The best way to obtain good plants, is from the seeds, which must be procured from America, for they never have produced any fruit in this country. The seeds should be sown in small pots filled with fresh loamy earth soon after they arrive, and should be placed under a hot-bed frame, where they may remain till the beginning of May, when they must be removed to a situation exposed to the morning sun, and screened from the sun in the middle of the day. In dry weather the pots must be watered, and kept clean from weeds; for as these seeds lie in the ground a whole year before the plants will come up, they should not be exposed to the sun the first summer, but the following autumn they should be removed, and placed under a frame, to protect the seeds from being injured by the frost; and if the pots are plunged into a moderate hot-bed the beginning of March, it will bring up the plants much sooner than they will otherwise rise; by which means they will get more strength the first summer, and be better able to resist the cold of the next winter. While these plants are very young, they will be in danger of suffering by severe frost; but when they have obtained strength, they will resist the greatest cold of our climate in the open air; therefore for the two or three first winters, it will be proper to keep them under shelter; so that the young plants may remain in the seed-pots all the first summer, and the following winter; and in the spring before they begin to shoot, they should be shaken out of the pots, and carefully separated so as not to break off their roots, and each planted in a small pot filled with light loamy soil, and plunged into a very moderate hot-bed, just to forward their taking fresh root; then they should be gradually inured to the open air, and during the following summer, the pots should be plunged into the ground, to prevent the earth from drying, in a situation where they may enjoy the morning sun, but screened from the great heat at noon. During the summer season, they will require to be frequently watered, and kept clean from weeds. The autumn following, they should be again placed under a hot-bed frame to screen them from frost; but they should enjoy the free air at all times, when the weather is mild. The April following, the plants may be shaken out of the pots, with the ball of earth to their roots, and planted where they are designed to remain.

This shrub delights in a moist, soft, loamy soil, and if it is planted in a sheltered situation, will endure the cold of our winters very well in the open air; but in dry land it is very subject to decay in warm seasons.

In the places where this shrub grows naturally; it produces great quantities of flowers, so that they seem covered with snow; which gave occasion to the inhabitants for titling it Snowdrop-tree; but in England the flowers are seldom so numerous; so do not make so good an appearance.

CHIRONIA. Lin. Gen. Plant. 227.

The CHARACTERS are;

The flower hath a permanent empalement of one leaf, cut into five oblong segments: it hath one petal, with a roundish tube, the size of the empalement, divided into five equal parts above, which spread open: it hath five short broad stamina, which are fastened to the top of the tube, and are terminated by large oblong summits, which join together, and after the flowers drop are spirally twisted. It hath an oval germen, situated in the center, supporting a slender declining style, crowned by a rising stigma in form of a head. The germen afterward becomes an oval capsule with two cells, filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia; the flower having five stamina and one style.

The SPECIES are,

1. **CHIRONIA** frutescens, capsulifera. Lin. Sp. Plant. 190. *Shrubby Chironia bearing capsules.* Centaurium minus Africanum, arborecens, latifolium, flore ruberrimo. Com. Rar. Pl. 8. tab. 8. *Lesser Tree-like African Centaury, with a broad leaf, and a very red flower.*

2. **CHIRONIA** frutescens baccifera. Lin. Sp. Plant. 190. *Shrubby berry-bearing Chironia.* Centaurium minus arborecens pulpiferum. Com. Rar. Pl. 9. tab. 9. *Lesser Tree-like Centaury with seeds surrounded with pulp.*

These plants grow naturally at the Cape of Good Hope, from whence their seeds were brought to Holland many years past, and the plants were raised in some of the curious gardens there, and have since been communicated to the curious in many parts of Europe. The seeds of the first sort were sent me from Paris, by Mr. Richard, gardener to the king at Versailles, from which I raised several plants, which have flowered in the Chelsea garden several years, but have not as yet perfected any seeds.

It hath a fibrous root, which spreads near the surface of the ground. The stalks are round, and inclining to be ligneous, but are of a very soft texture; these grow from two to three feet high, having several branches on every side, which grow erect, garnished with succulent leaves, which are an inch or more in length, and an eighth part of an inch broad, ending in an obtuse point. At the ends of each shoot the flowers are produced, which are tubulous, and spread open at the top like those of Periwinkle; these are of a bright red colour, and when there are a large number of the flowers open on the same plant, they make a very fine appearance. In the center of the flower is placed an oval germen, upon which there is fixed a recurved style, having a blunt stigma at the top, surrounded by five incurved stamina, each supporting a large summit. When the flowers fall away, the germen becomes an inflated capsule, which is filled with small seeds. The flowers are produced from June to autumn, and the seeds ripen in October. This plant should be placed in an airy glass-case in winter, where it may enjoy a dry air and much sun, but will not thrive in a warm stove; nor can it be well preserved in a common green-house, because a damp moist air will soon cause it to rot.

The seeds of this plant should be sown in small pots filled with light sandy earth, soon after they are ripe, and plunged into a moderate hot-bed, and must be frequently but gently watered; sometimes the seeds will lie a long time in the ground, so that if the plants do not appear the same season, the pots should not be disturbed, but preserved in shelter till the following spring, and then plunged into a fresh hot-bed, which will bring up the plants in a short time, if the seeds are good. When the plants are fit to remove, they should be transplanted into

small pots, four or five in each pot; then plunge the pots into a moderate hot-bed, and sprinkle them with water, and shade them every day from the sun till they have taken new root; after which they must have a large share of air in warm weather, to prevent their drawing up weak: when the plants have obtained some strength, they must be gradually inured to bear the open air; but when they are exposed abroad, if there should happen much rain, the plants must be screened from it, otherwise it will cause them to rot: when the plants have filled the pots with their roots, they should be parted, and each put into a separate pot filled with light sandy earth, not rich with dung, placing them in the shade till they have taken fresh root; then they may be removed to a warm sheltered situation, and mixed with such other plants as require but little water; in which situation they may remain till autumn, when they must be placed in a dry airy glass-case; and in the winter should have very little wet, but must enjoy the sun as much as possible; and in mild weather should have fresh air admitted to them, but must be protected from frost: with this management, the plants will thrive and produce flowers the second year from seed.

The second sort rises with a firmer stalk than the first, which is round, jointed, and divides upward into a greater number of branches, garnished with short narrow leaves, which are pretty thick and succulent. The flowers are produced at the end of the branches, in the same manner as those of the first, which are of a fine red colour, but not half so large as the flowers of the first; when these fall away, they are succeeded by oval pulpy berries, in which are included many small seeds. This sort continues flowering great part of summer and autumn, and in warm seasons the seeds will ripen in England.

It is propagated by seeds in the same manner as the former sort, and the plants require the same treatment.

CHIVES, as they are by some titled, are the stamina, which support the summits in the center of flowers.

CHIVETS, in French, are the small parts, or little offsets from the roots of bulbous plants, by which they are propagated.

CHONDRILLA. Lin. Gen. Plant. 815. Tourn. Inst. R. H. 475. tab. 268. [of *Χόνδριον*, Gr. a cartilage.] Gum Succory.

The CHARACTERS are,

The common empalement is composed of many narrow cylindrical scales, which are equal. The flower is composed of many hermaphrodite florets, which are uniform, and lie imbricatum, like tiles on a house; these have one petal, which is stretched out on one side like a tongue, and are indented at the top in four or five segments; they have each five short hairy stamina, terminated by cylindrical summits. The germen is situated under the floret, having a style the length of the stamina, crowned by two reflexed stigmas; the germen afterward becomes a single, oval, compressed seed, crowned with a single down, and inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia æqualis. The flowers of this section are composed of only hermaphrodite florets, which are fruitful.

We have but one SPECIES of this genus, viz.

CHONDRILLA (*Juncea*.) Lin. Hort. Cliff. 383. Gum Succory. *Chondrilla juncea viscosa arvensis*. C. B. P. 30. Viscous Field Gum Succory with rusby stalks.

This plant grows naturally in Germany, Helvetia, and France, on the borders of the fields, and is seldom preserved in gardens, because the roots are very apt to spread, and become troublesome weeds; and the seeds having down on their tops, are carried by the wind to a great distance, so that the neighbouring ground is filled with the plants, the roots of this strike deep into the ground, and spread out with thick fibres on every side, each of which, when cut, or broken into many parts, will shoot up a plant; so

that when this plant hath obtained possession of the ground, it is very difficult to root out. The root sends out a great number of slender stalks, which at their bottom are garnished with oblong sinuated leaves, but those above are very narrow and entire. The flowers are produced from the side and top of the branches, which are like those of Lettuce, and are succeeded by seeds of the same form, crowned with down. It flowers in July, and the seeds ripen in September.

The other species of this genus which were enumerated in the former edition, are referred to the *Lactuca* and *Crepis*.

CHRISTMAS FLOWER, or Black Hellebore. See *HELLEBORUS*.

CHRISTOPHORIANA. See *ACTEA*.

CHRISANTHEMOIDES OSTEOSPERMON. See *OSTEOSPERMUM*.

CHRYSANTHEMUM. Tourn. Inst. R. H. 491. tab. 280. Lin. Gen. Plant. 866. *Leucanthemum*. Tourn. Inst. R. H. 492. [*χρυσάνθεμον*, Gr. from *χρυσος*, gold, *άνθος*, a flower; that is to say, Golden Flower.] Corn Marigold.

The CHARACTERS are,

It hath a compound flower, the rays being composed of female florets, which are extended on one side like a tongue, and are indented in three segments at the end; these have an oval germen, supporting a slender style, crowned by two obtuse stigmas. The hermaphrodite florets which compose the disk, are funnel-shaped the length of the empalement, but are divided into five segments at the top, which are spread open; these have five short hairy stamina, terminated by tubular cylindrical summits, and have an oval germen, with style and stigma like the female; the germen afterward becomes a single, oblong, naked seed.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua. In this section all the central florets which compose the disk, are hermaphrodite and fruitful, and the rays are composed of female florets.

The SPECIES are,

1. **CHRYSANTHEMUM** (*Segetum*) foliis amplexicaulibus, supernè laciniatis, infernè dentato-ferratis. Hort. Cliff. 416. Corn Marigold with leaves embracing the stalks, the upper being jagged, and the lower indented like a saw. *Chrysanthemum segetum*. Clus. Hist. 1. p. 334. Corn Marigold.
2. **CHRYSANTHEMUM** (*Leucanthemum*) foliis amplexicaulibus, oblongis, supernè ferratis, infernè dentatis. Hort. Cliff. 416. Corn Marigold with oblong leaves embracing the stalks, the upper ones being sawed, and the lower indented. *Bellis sylvestris caule folioso major*. C. B. P. 261. Greater wild Daisy with a leafy stalk.
3. **CHRYSANTHEMUM** (*Scrobinum*) foliis lanceolatis, supernè ferratis, utrinque acuminatis. Hort. Cliff. 416. Corn Marigold with spear-shaped leaves, those above being sawed, and pointed on all sides. *Bellis major, radice repente, foliis latoribus, ferratis*. Mor. Hist. 3. p. 29. Greater Daisy with a creeping root, and broad sawed leaves.
4. **CHRYSANTHEMUM** (*Montanum*) foliis imis spathulato-lanceolatis, ferratis, summis linearibus. Sauv. Monsp. 87. Corn Marigold with lower leaves pointed like a spear-shaped spatula, and sawed, and the upper ones linear. *Leucanthemum montanum minus*. Tourn. Inst. 492. Lesser Mountain Ox-eye.
5. **CHRYSANTHEMUM** (*Graminifolium*) foliis linearibus, subintegerrimis. Sauv. Monsp. 87. Corn Marigold with narrow leaves, which are entire. *Leucanthemum gramineo folio*. Tourn. Inst. 493. Ox-eye with a Grass leaf.
6. **CHRYSANTHEMUM** (*Alpinum*) foliis pinnatifidis, laciniis parallelis, integris, caule unifloris. Lin. Sp. Plant. 889. Corn Marigold with many pointed leaves, whose segments are parallel and entire, and one flower on each foot-stalk. *Leucanthemum Alpinum, foliis Coronopi*. Tourn. Inst. R. H. 493. Alpine Ox-eye with a Hartshorn leaf.

7. **CHRYSANTHEMUM** (*Corymbiferum*) foliis pinnatis, incisiferratis, caule multifloro. Prod. Leyd. 174. *Corn Marigold with winged leaves, sawed segments, and many flowers upon a stalk.* Tanacetum montanum inodorum, minore flore. C. B. P. 132. *Unfavoury Mountain Tansy with a lesser flower.*

CHRYSANTHEMUM (*Coronarium*) foliis pinnatifidis, incisis, extrorsum latoribus. Hort. Cliff. 416. *Corn Marigold with wing-pointed cut leaves, whose exterior parts are broadest.* Chrysanthemum Creticum. Clus. Hist. 1. p. 334. *Corn Marigold of Crete.*

9. **CHRYSANTHEMUM** (*Monspeliensium*) foliis imis palmatis, foliolis linearibus, pinnatifidis. Sauv. Monsp. 304. *Corn Marigold, whose lower leaves are palmated, and the smaller linear, ending in many points.* Leucanthemum montanum foliis Chrysanthemi. Tourn. Inst. 492. *Mountain Ox-eye with Corn Marigold leaves.*

10. **CHRYSANTHEMUM** (*Frutescens*) fruticosum, foliis linearibus dentato-trifidis. Hort. Cliff. 417. *Shrubby Corn Marigold with narrow leaves, having three indented points.* Leucanthemum Canariense, foliis Chrysanthemi, Pyrethri sapore. Tourn. Inst. 493. *Canary Ox-eye with Corn Marigold leaves, and the taste of Pelitory.*

11. **CHRYSANTHEMUM** (*Flosculosum*) flosculis omnibus uniformibus, hermaphroditis. Hort. Cliff. 417. *Corn Marigold, whose florets are all uniform and hermaphrodite.* Bellis spinosa, foliis Agerati. C. B. P. 262. *Prickly Daisy with Maudlin leaves.*

12. **CHRYSANTHEMUM** (*Pallidum*) foliis linearibus, infernè apice dentatis, supernè integerrimis, pedunculis nudis unifloris. *Corn Marigold with narrow leaves, those on the lower part being indented at their points, the upper entire, and naked foot-stalks with one flower.* Chrysanthemum pallidum minimis, imisque, foliis incisis superioribus integris, capillaribus. Barrel. Icon. 421. *Least Corn Marigold, with the under and lesser leaves divided, the upper entire.*

The first sort is the common Corn Marigold, which grows naturally amongst the corn, and the borders of the corn-fields in divers parts of England, so is rarely admitted into gardens; but we have inserted this and the next to introduce the other species.

The second sort is the greater Daisy, which stands in the list of medicinal plants in the College Dispensatory: this grows naturally in moist pastures, almost every where in this country. It rises with stalks near two feet high, garnished with oblong indented leaves, which embrace the stalks with their base. The foot-stalks are each terminated by one white flower, shaped like those of the Daisy, but four times as large. It flowers in June.

The third sort grows naturally in North America, but hath been long preserved in the English gardens. The roots of this plant creep far under the surface, and send up strong stalks three or four feet high, garnished with long sawed leaves, ending in points; the stalks divide upward into many smaller, each being terminated by a large, white, radiated flower; these appear in September. It multiplies very fast by its creeping roots, and will thrive in any soil or situation.

The fourth sort grows naturally upon the Alps, and other mountainous places. I received this from Verona, near which place it grows in plenty: this sends up a single stalk a foot high, garnished with entire leaves above, but the under leaves are sawed on the edges. The stalk is terminated by one large white flower, shaped like those of the third sort. It flowers in June, and the seeds ripen in August. This sort may be propagated by seeds, which, if sown in a shady border, will come up in about six weeks; and the plants, when fit to remove, may be transplanted into a shady border, where they are to remain, and will require no other care but to keep them clean from weeds.

The fifth sort grows naturally about Montpellier; this hath a perennial root, from which springs up many narrow Grass-like leaves, and, between them, stalks which rise a foot and a half high, garnished

with leaves of the same form as those below. The stalks are each terminated by one large white flower, with a yellow disk or middle. This flowers in June, but rarely perfects seeds in England, so is propagated only by parting the roots: the best time for this is in autumn, that the plants may get good root before winter.

The seventh sort grows naturally on the Alps, and other mountainous places in Germany: this sends out upright stalks, garnished with leaves cut into many parallel segments, somewhat like those of Buckshorn Plantain. The stalks rise a foot and a half high, and are each terminated by a single flower of the same form with those of the last: it hath a perennial root, and may be propagated in the same manner as the other.

The eighth sort has been many years cultivated in the gardens for the beauty of its flowers. Of this there are single and double with white, and the same with yellow flowers; and as these do not differ from each other in any thing except in the colour of their flowers, therefore they are generally esteemed but one species; but this difference is constant, for I have never found the seeds saved from the white, produce plants with yellow flowers, nor those of the yellow produce white.

There is also a variety of these colours with fistular florets, which has accidentally risen from seeds of the other; these are generally titled Quill-leaved Chrysanthemum; but as the seeds saved from these degenerate to the common sorts, so they do not merit a particular denomination.

These plants are always esteemed as annual, so the seeds are usually sown upon a slender hot-bed in the spring, and the plants treated in the same manner as the African Marigold, for the culture of which we shall refer the reader to that article; but as the plants which rise from seeds, do many of them produce single flowers, although the seeds are saved from the best double flowers, therefore many persons now propagate these plants from cuttings, whereby they continue the double sorts only; these cuttings, taken from the plants the beginning of September, and planted in pots, will readily take root; and if they are placed under a hot-bed frame to screen them from the frost in winter, letting them have free air in mild weather, they will live through the winter; and in the spring these plants may be transplanted into the borders of the flower-garden, where they will flower in June, and continue in succession till the frost puts a stop to them; by this method all the varieties may be continued without variation, but the plants which are propagated this way by cuttings will become barren soon, so will not produce seeds.

The ninth sort is a perennial plant, sending out many stalks from the root, which divide into branches, garnished with pretty thick leaves, deeply cut into many segments, like those of the last sort; these are of a pale green; the flowers are produced at the end of the branches, standing upon pretty long naked foot-stalks; they are very like those of the common Greater Daisy, in size and colour. It flowers in June, and continues till the end of September. This sort ripens seeds every year in England, by which the plant is easily propagated; for if the seeds are sown in the spring on a common border, the plants will come up in six weeks; when these are fit to remove, they may be transplanted into a nursery-bed at about a foot distance every way, and kept clean from weeds till autumn, when they may be removed to the places where they are designed to remain. As these plants extend their branches pretty far on every side, they should be allowed at least two feet room; therefore they are not very proper furniture for small gardens, where there is not room for these large growing plants; but in large gardens, these may have a place for the sake of variety.

If these plants are planted in poor dry land, or upon lime-rubbish, they will not grow so vigorous as in good ground, so they will endure the cold better, and

C H R

and continue longer; for when their leaves and branches are replete with moisture, they are very apt to rot in the winter, so are seldom of long duration; but where the plants have grown from the joints of old walls, I have known them continue in vigour several years.

The tenth sort grows naturally in the Canary Islands, from whence it was first brought to England, where it has been long an inhabitant in some curious gardens. It has been frequently called by the gardeners Pellitory of Spain, from the very warm taste which it hath, much resembling the taste of that plant.

This rises with a shrubby stalk near two feet high, dividing into many branches, garnished with pretty thick succulent leaves, of a grayish colour, cut into many narrow segments, which are divided into three parts at their extremity. The flowers come out from the wings of the leaves, standing upon naked foot-stalks singly, which greatly resemble those of the common Chamomile; there is a succession of flowers upon the same plants great part of the year, for which it is chiefly esteemed. This plant will perfect seeds in England, when the seasons are favourable; but as the cuttings of it take root so easily, if planted during any of the summer months, the seeds are rarely sown.

As this plant is a native of warm countries, it will not live in the open air in England during the winter season; therefore when the cuttings have made good roots, they should be each planted into a separate pot, and placed in the shade till they have taken fresh root; then they may be removed to a sheltered situation, where they may remain till autumn, at which time they must be removed into the green-house to protect them from frost; but in mild weather they should have plenty of free air, and, during the winter, they should be frequently refreshed with water, but it must not be given them in too great plenty. In summer they will require more moisture, and should be treated in the same manner as other hardier kinds of exotic plants.

The eleventh sort grows naturally at the Cape of Good Hope, from whence the seeds were brought many years past to Holland, where the plants were first raised, and from thence all the other parts of Europe have been supplied with this plant. It rises with a shrubby stalk about two feet high, which divides into many slender branches upward, garnished with oblong leaves, much indented on their edges, each indenture terminating in a soft spine; these are of a pale green, set close to the branches. The flowers are produced on short foot-stalks from the wings of the leaves, toward the upper part of the branches; these are globular, and formed of a great number of hermaphrodite florets, which are tubular and even, having no rays, so are naked, and of a deep yellow colour. The flowers appear in June, and continue in succession till the frost stops them. This may be propagated by cuttings in the same manner as the last, and the plants should be treated in the same way. The twelfth sort grows naturally about Madrid: this hath a low shrubby stalk, which seldom rises a foot high, putting out several slender ligneous branches, garnished with narrow, pale, green leaves; those on the lower part of the branches are indented at their extremity in several parts, but the upper leaves are entire; from the end of each branch is produced a naked foot-stalk six inches long, sustaining one radiated flower, of a sulphur colour. The flowers come out in June and July, but there is seldom any seeds ripened in England; this sort must be sheltered under a common frame in winter, for unless the winter proves very favourable, the plants will not live in the open air here. It may be propagated by cuttings in summer, as the two last sorts, but these cuttings do not so readily take root as those do.

CHRYSOBALANUS. Lin. Gen. Plant. 585. Icaco. Plum. Nov. Gen. 44. Cocoa Plumb.

The CHARACTERS are,

The empalement of the flower is of one leaf, divided into

C H R

five parts, almost to the middle. The flower hath five petals, which spread open, and ten stamina, five of which are longer than the petals; the other are shorter, and are terminated by heart-shaped summits. In the center is situated an oval germen, supporting a trifid short style, crowned by obtuse stigmas. The germen afterward becomes an oval fleshy berry, inclosing a nut with five longitudinal furrows.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, intitled Polyandria Monogynia; but it would be more properly placed in the third section of his tenth class, for the flowers have ten stamina and three styles.

The SPECIES are,

1. **CHRYSOBALANUS** (*Icaco*) foliis ovatis, emarginatis, floribus racemosis, caule fruticoso. *Chrysobalanus with oval indented leaves, flowers growing in bunches, and a shrubby stalk.* Frutex Cotini ferè folio crasso, in summitate deliquium patiente, fructu ovali cæruleo ossiculum angulosum continente. Catesb. Car. *The Cocoa Plumb.*
2. **CHRYSOBALANUS** (*Purpurea*) foliis decompositis, foliolis ovatis integerrimis. *Chrysobalanus with compounded leaves, whose lobes are oval and entire.* Icaco fructu purpureo. Plum. Nov. Gen. 44. *Icaco with purple fruit.*

The first sort grows naturally in the Bahama Islands, and in many other parts of America, but commonly near the sea. It rises with a shrubby stalk about eight or ten feet high, sending out several side branches, covered with a dark brown bark, spotted with white; these are garnished with oval stiff leaves, which are indented at the end, in form of a heart, placed alternately on the branches. From the wings of the leaves, and also at the division of the branches, the flowers are produced, which grow in loose bunches; these are small and white, having many stamina in each, which are joined to the petals of the flowers, terminated by yellow summits. The flowers are succeeded by oval Plumbs about the size of Damsons; some of these are blue, some red, and others yellow; they have a sweet luscious taste. The Spaniards in the island of Cuba, make a conserve of these fruits. The stone of the Plumb is shaped like a Pear, and hath five longitudinal ridges on it. This grows naturally on moist land.

The seeds of the second sort were sent me from Jamaica, with Plumier's title; the stones were exactly the same shape of those of the former, but the plants have leaves compounded of several winged lobes, which are branched out opposite, each having six or seven pair of pinnæ (or lobes.) This sort hath not flowered in England, so I can give no farther account of it.

As these trees are natives of the warm parts of America, so they will not thrive in England, unless they are kept in a warm stove. They are propagated by seeds, which must be obtained from the countries where the plants naturally grow; these must be sown in the spring in small pots filled with light earth, and plunged into a hot bed of tanners bark, observing frequently to water the pots; but not let them have much at each time. In six weeks the plants will come up, and, if properly managed, will be fit to remove in a month's time after, when they should be carefully separated, and each planted into a separate small pot filled with light kitchen-garden earth, and then plunged into the hot-bed again, observing to shade them from the sun till they have taken fresh root; after which they must have air every day in proportion to the warmth of the season, and their waterings during the summer should be frequent, but sparing. In the autumn the plants must be removed into the bark-stove, and plunged into the tan-bed; and in winter the plants must not have too much water, lest it occasions their throwing off their leaves. In summer they must have a good share of air, and the plants in the stove should be constantly treated in the same manner as other tender plants from the same countries.

CHRY-

CHRYSOCOMA. Lin. Gen. Plant. 845. Dillen. Gen. 14. Coma aurea. Boerh. 1. p. 121. Goldyllocks.

The CHARACTERS are,

The common empalement is imbricated, the scales are narrow; the outer being convex and pointed; the flower is composed of many hermaphrodite florets, which are tubular, equal, and funnel-shaped, cut into five segments at the brim, which turn back; these have each five short slender stamina, terminated by cylindrical summits; they have an oblong germen, supporting a slender style, crowned by two oblong depressed stigmas. The germen afterward becomes a single, oblong, compressed seed, crowned with hairy down.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Aequalis; the plants of this section have only hermaphrodite florets, which are fruitful.

The SPECIES are,

1. **CHRYSOCOMA** (*Linofyris*) herbacea, foliis linearibus, glabris, calycibus laxis. Lin. Sp. Plant. 841. *Herbaceous Goldyllocks with narrow smooth leaves, and loose empalements.* Coma aurea Germanica linariæ folio. Park. Theat. 688. *German Goldyllocks.*
2. **CHRYSOCOMA** (*Biflora*) herbacea paniculata, foliis lanceolatis trinerviis, punctatis, nudis. Lin. Sp. Plant. 841. *Herbaceous Goldyllocks with flowers growing in panicles, and spear-shaped leaves, having three nerves, and yellow flowers growing in umbels.*
3. **CHRYSOCOMA** (*Coma Aurea*) fruticosa foliis linearibus dorso decurrentibus. Hort. Cliff. 397. *Shrubby Goldyllocks with very narrow leaves, whose back parts run along the stalks.* Coma aurea Africana fruticans, foliis linariæ angustis, major. Com. Hort. Amst. 2. p. 89. *Greater shrubby African Goldyllocks, with narrow Toad-flax leaves.*
4. **CHRYSOCOMA** (*Cernua*) subfruticosa, foliis linearibus subtus pilosis, floribus ante florescentiam cernuis. Hort. Cliff. 397. *Shrubby Goldyllocks with very narrow hairy leaves, and flowers nodding before they are blown.* Coma aurea foliis linariæ angustioribus minor. Hort. Amst. 2. p. 89. *Lesser Goldyllocks with narrower Toad-flax leaves.*
5. **CHRYSOCOMA** (*Ciliata*) suffruticosa, foliis linearibus rectis, ciliatis ramis pubescentibus. Lin. Sp. Plant. 481. *Shrubby Goldyllocks with narrow leaves and downy branches.* Conyza Africana, tenuifolia, subfrutescens, flore aureo. Hort. Elth. 104. tab. 68. *Narrow-leaved, African, shrubby Fleabane, with a golden flower.*

The first sort grows naturally in Germany, and also in France and Italy; this hath a perennial root; the stalks rise two feet and a half high, are round, stiff, and closely garnished with long, narrow, smooth leaves, which come out without any order, of a pale green colour; the upper part of the stalk divides into many slender foot-stalks, each sustaining a single head of flowers, which are composed of many hermaphrodite florets, contained in one common empalement, having very narrow scales. The flowers are of a bright yellow, and stand disposed on the top of the stalk, in form of an umbel. These appear in July; and in favourable seasons are succeeded by seeds, which ripen in September, soon after which the stalks decay to the root, and new ones arise the following spring.

This plant is generally propagated by parting of the roots, that being the most expeditious method; for the seedling plants do not flower till the second or third year. The best time to remove the plants and part their roots, is soon after the stalks decay in autumn, that the plants may get fresh roots before winter. It delights in a dry loose soil, in which it will live in the open air, and propagate by its roots very fast; but in strong wet land, the roots often rot in winter.

The second sort grows naturally in Siberia, from whence the seeds were sent to Petersburg, part of which I received from the late Dr. Amman, who was professor of botany in that university. This plant hath a perennial creeping root, which spreads on

every side to a considerable distance, sending up many erect stalks, garnished with flat spear-shaped leaves, ending in points; these are rough, and have three longitudinal veins; the upper part of the stalks branch out, and form loose panicles of yellow flowers, which are larger than those of the former sort. This flowers in June and July, and the seeds ripen in autumn.

It propagates too fast by its creeping roots to be admitted into the flower-garden, for the roots will often extend two or three feet every way in the compass of one year, so that they will interfere with the neighbouring flowers; but as the plants will grow in any soil or situation, so a few roots may be planted on the side of extensive rural walks round the borders of fields, where they will require no care, and their flowers will make a good appearance, and continue long in beauty.

The third sort grows naturally at the Cape of Good Hope. This rises with a ligneous stalk about a foot high, dividing into many small branches, which are garnished with narrow leaves, of a deep green, coming out on every side without order; the back part of each leaf hath a small short appendix, which runs along the stalks. The flowers are produced at the end of the branches, on slender naked foot-stalks; these are of a pale yellow, and shaped like those of the former sorts, but are larger. This plant flowers great part of the year, for which it is chiefly esteemed; the seeds ripen very well in autumn, which if sown on a common border of light earth in the spring, the plants will come up, and may be transplanted into pots, to be removed into shelter in winter, for these plants will not live through the winter in the open air in England.

The most expeditious method of propagating this plant is by cuttings, which, if planted in a common border in any of the summer months, and covered with hand-glasses, will easily take root, provided they are shaded from the sun and duly watered: when these have gotten good roots they should be carefully taken up, and each planted in a separate pot, filled with light earth, placing them in the shade till they have taken new root; then they may be exposed with other hardy exotic plants till autumn, when they must be removed into the green-house during the winter season; they should enjoy a large share of free air in mild weather, for they only require protection from frost, so must not be too tenderly treated.

The fourth sort is a native of the Cape of Good Hope, from whence I received the seeds; this is a less plant than the former, it hath a shrubby stalk, branching out in the same manner; the leaves are shorter, and a little hairy; the flowers are not half so large, of a pale sulphur colour, and nod on one side before they are blown. This also flowers great part of the year, and ripens seeds very well; but this is generally propagated in the same manner as the former, and the plants require the same treatment.

The fifth sort is also a native of the same country as the two former; this hath a low shrubby stalk, which branches out on every side, very narrow, short, rough, and reflexed; the flowers stand single on the top of naked foot-stalks, which arise from the upper part of the branches; these flowers are larger than those of the last, and stand erect. This plant requires the same treatment as the two former, and is propagated by cuttings in the same manner.

CHRYSOPHYLLUM. Lin. Gen. Plant. 233. Cainito. Plum. Nov. Gen. 9. tab. 9. The Star Apple.

The CHARACTERS are,

The empalement is permanent, and consists of five small, roundish, concave petals; the flower is composed of five petals, which spread open, and are cut in the middle into two parts; it hath five stamina placed alternate to the segments of the petals, terminated by heart-shaped summits: the oval germen is situated in the center, support-

ing a short style, crowned by an obtuse stigma. The germen afterward becomes a large, oval, fleshy fruit, inclosing three or four flat seeds, having hard shells.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. CHRYSOPHYLLUM (*Cainito*) foliis ovatis, parallelis striatis subtus, tomentoso-nitidis. Jacq. Amer. 15. *Chrysophyllum with oval leaves, with parallel veins and neat woolly leaves on their under side.* Cainito folio subtus aureo, fructu olivæ formi. Plum. Nov. Gen. 10. *The Damson-tree.*

2. CHRYSOPHYLLUM (*Glabrum*) foliis utrinque glaberrimis. Jacq. Amer. 15. *Chrysophyllum with very smooth leaves.* Cainito folio subtus aureo, fructu maliformi. Plum. Nov. Gen. 10. *The Star Apple.*

These trees grow naturally in the West-Indies, where the first sort rises from twenty to thirty feet high, dividing into many branches, garnished with oval leaves, smooth above, and of a gold colour on their under side; the flowers come out from the side of the branches, at the setting on of the leaves, in round clusters, which are succeeded by oval, smooth, pulpy fruit, inclosing three or four hard flat seeds.

The second sort rises with an upright trunk to the height of thirty or forty feet, dividing into many slender branches, garnished with spear-shaped leaves, coming out without order; from the wings of the leaves, and also at the extremity of the branches, the flowers are produced in bunches, which are succeeded by round pulpy fruit the size of a Golden Pippin, containing many flat hard seeds.

The fruit of both these trees is very rough and astringent at first, but by lying some time after they are gathered, they become mellow, like the Medlar. The timber of both these trees is used in buildings, and for shingles to cover houses.

These plants are preserved in several curious gardens for the beauty of their leaves, especially the first sort, whose under sides shine like satin, the upper sides are of a deep green. The leaves continue all the year, so make a very pretty appearance in the stove at all seasons.

These trees, being natives of the warmest parts of the world, cannot be preserved in this country, without being kept in the warmest stoves; and should always remain in a hot-bed of tanners bark, otherwise they will make but little progress. They are propagated by seeds, which must be procured from the places of their growth, for they do not produce fruit in Europe. These seeds must be fresh, otherwise they will not grow; and if they are sent over in sand, it will preserve them from drying too much; when the seeds arrive, they must be sown as soon as possible in small pots filled with light fresh earth, and plunged into a good hot-bed of tanners bark. If the seeds are good, and the bed in a proper temperature of warmth, the plants will appear in five or six weeks; and in about two months after, will be strong enough to transplant; in doing of which, the plants, with all the earth, should be shaken out of the pots very carefully, and separated with their roots entire, and each planted into a single small pot filled with fresh rich earth, and plunged again into a hot-bed of tanners bark, watering and shading them until they have taken fresh root. If the hot-bed in which these plants are plunged, is from time to time stirred, and a little fresh tan added to it, to renew the heat when it declines, the plants will make good progress, and in three or four months will be near a foot high, and may then be shifted into pots a small size larger than those they before were in. If these plants are constantly kept in a warm bed in the stove, and shifted twice a year, to renew the earth to their roots, they will thrive very fast, and put out their side branches, so as to make a handsome appearance in the stove, with other curious plants of the same country; for though they do not produce

either flowers or fruit, yet as they keep their leaves through the year, which are so very beautiful, they deserve a place in the stove, better than most other plants. The chief care they require, is to keep them constantly in a proper degree of heat, and never to put them into too large pots; and in winter they should not have too much water, about twice a week will be often enough to water them; and in the depth of winter, they should not have much at each time.

These trees are frequently propagated in the West-Indies, by planting of their branches (as I have been informed by persons of credit;) but I have not heard of their being propagated in England by that method.

CHRYSOSPLENium. Lin. Gen. Plant. 493. [*χρυσόσπληνιον*, of *χρυσός*, Gold, and *σπλήν*, the spleen; q. d. a plant, the flowers of which are of a golden colour, and good against diseases of the spleen.] Golden Saxifrage.

The CHARACTERS are,

The empalement is divided into four or five parts, which spread open, are coloured, and permanent. The flower hath no petals, but eight or ten stamina, which are short, erect, and stand opposite to the angles of the empalement, terminated by single summits: the germen is immersed in the empalement, supporting two short styles, crowned by obtuse stigma. The germen afterward becomes a capsule with two beaks, opening with two valves, and filled with small seeds.

This genus of plants is ranged in the second section of Linnæus's tenth class, intitled Decandria Digynia, the flowers having ten stamina and two styles.

The SPECIES are,

1. CHRYSOSPLENium (*Alternifolium*) foliis alternis. Flor. Suec. 317. Golden Saxifrage with alternate leaves. Saxifraga aurea foliis pediculis oblongis insidentibus. Rail Syn. Hist. 206. Golden Saxifrage with leaves growing upon long foot-stalks.

2. CHRYSOSPLENium (*Oppositifolium*) foliis oppositis. Sauv. Monsp. 128. Golden Saxifrage with opposite leaves. Chrysosplenium foliis amplioribus auriculatis. Tourn. Inst. 146. Golden Saxifrage with larger eared leaves.

These two plants are found growing wild in many parts of England, upon marshy soils and bogs, as also in moist shady woods, and are seldom propagated in gardens; where, if any person has curiosity to cultivate them, they must be planted in very moist shady places, otherwise they will not thrive. They flower in March and April.

CIBOULS, or CHIBOULS. See CEPA.

CICER. Lin. Gen. Plant. 783. Tourn. Inst. R. H. tab. 210. [This plant is called Cicer, of *Κίκυς*, strength, because it is said to strengthen: it is also called Arietaria, because the seeds of it resemble the head of a ram.] Cicer, or Chick Pease.

The CHARACTERS are,

The empalement of the flower is cut into five segments, four of which lie upon the standard; the two middle, which are the longest, are joined, the other is under the keel. The flower is of the butterfly kind, the standard is large, roundish, and plain; the wings are much shorter and obtuse, the keel is shorter than the wings, and is sharp-pointed. It hath ten stamina, nine of them are joined, and the tenth is separate, terminated by single summits. It hath an oval germen supporting a single style, crowned by an obtuse stigma. The germen afterward becomes a turgid swelling pod of a rhomboidal figure, inclosing two roundish seeds, with a protuberance on their side.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, from the flower having ten stamina joined in two bodies.

There is but one SPECIES of this genus, viz.

- CICER (*Arietinum*) foliolis serratis. Hort. Cliff. 370. Chick Pease with sawed leaves. Cicer sativum. C. B. P. 347. Garden Chick Pease.

There is a variety of this with a red seed, which differs from it in nothing but the colour.

It is much cultivated in Spain, being one of the ingredients in their olios, and is there called Garavance; it is also cultivated in France, but in England it is rarely sown.

This plant is annual, shooting out several hairy stalks from the root, which are about two feet long; garnished with long winged leaves of a grayish colour, composed of seven or nine pair of small roundish leaves (or lobes) terminated by an odd one, which are sawed on their edges. From the side of the branches come out the flowers, sometimes one, at other times two together. They are shaped like those of Pease, but are much smaller and white, standing on long foot-stalks; these are succeeded by short hairy pods, including two seeds in each, which are the size of common Pease, but have a little knob or protuberance on one side.

The seeds of this plant may be sown in the spring, in the same manner as Pease, making drills with a hoe, about an inch and a half deep, in which the seeds should be sown at about two inches asunder, then with a rake draw the earth into the drill to cover the seeds. The drills should be made at three feet distance from each other, that there may be room for their branches to spread, when the plants are fully grown, as also to hoe the ground between them, to keep it clean from weeds, which is all the culture these plants require.

This plant flowers in June, and the seeds ripen in August; but unless the season proves warm and dry, the plants decay in this country before the seeds are ripe.

CICHORIUM. Lin. Gen. Plant. 825. Tourn. Inst.

R. H. tab. 272. [*κικώριον*, or *κικώρειον*, of *κικέω*, to find, because found every where in walking.] Succory.

The CHARACTERS are,

The flower hath a common scaly empalement, which at first is cylindrical, but is afterward expanded; the scales are narrow, spear-shaped, and equal. The flower is composed of many hermaphrodite florets, which are plain, uniform, and stand circularly, each having one petal, which is tongue-shaped, and cut into five segments. They have five short hairy stamina, terminated by five-cornered cylindrical summits. The germen is situated under the petal, supporting a slender style, crowned by two turning stigmas: the germen afterward becomes a single seed, inclosed with a down, and shut up in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia æqualis. The plants of this section have only hermaphrodite fruitful florets.

The SPECIES are,

1. **CICHORIUM** (*Intybus*) floribus geminis sessilibus, foliis runcinatis. Flor. Suec. 650. Succory with two flowers sitting close to the stalk. *Cichorium sylvestre* five officinarum. C. B. P. 126. Wild Succory.
2. **CICHORIUM** (*Spinosum*) caule dichotomo spinoso floribus axillaribus sessilibus. Hort. Cliff. 388. Succory with a prickly forked stalk. *Cichorium spinosum*. C. B. P. 126. Prickly Succory.
3. **CICHORIUM** (*Endivia*) floribus solitariis pedunculatis, foliis integris, crenatis. Hort. Cliff. 389. Succory with single flowers on foot-stalks, and entire crenated leaves. *Cichorium latifolium*, five *endivia vulgaris*. C. B. P. 125. Broad-leaved Succory, or common Endive.
4. **CICHORIUM** (*Crispum*) floribus solitariis pedunculatis, foliis limbratis, crispis. Succory with single flowers on foot-stalks, and fringed curled leaves. *Endivia crispa*. C. B. P. 125. Curled Endive.

The first sort grows naturally by the sides of roads and in shady lanes; in many parts of England: this has been supposed to be no other way differing from the garden Succory, but by the latter being cultivated in gardens; indeed, most of the writers on botany, have confounded the two sorts together; for the Garden Succory which is described in most of the old books, I take to be the broad-leaved Endive, which is the third sort here enumerated, for I have many years cultivated both sorts in the garden, without finding either of them alter. There is an essential

difference between these, for the wild Succory hath a perennial creeping root, whereas the other is at most but a biennial plant; and if the seeds of the latter are sown in the spring, the plants will flower and produce seeds the same year, and perish in autumn, so that it may rather be called annual. The wild Succory sends out from the roots long leaves, which are jagged to the midrib, each segment ending in a point; from between these arise the stalks, which grow from three to four feet high, garnished with leaves, shaped like those at the bottom, but are smaller, and embrace the stalks at their base. These branch out above into several smaller stalks, which have the same leaves, but smaller and less jagged; the flowers are produced from the side of the stalks, which are of a fine blue colour; these are succeeded by oblong seeds, inclosed in a down. It flowers in June and July, and the seeds ripen in September.

The second sort grows naturally on the sea-coasts in Sicily and the islands of the Archipelago. This sends out from the root many long leaves, which are indented on their edges, spreading flat on the ground; from between these arise the stalks, which have very few leaves, and those small and entire: the stalks are divided in forks upward, from between these come out the flowers, which are of a pale blue, and are succeeded by seeds shaped like those of the common sort; the ends of the smaller branches are terminated by star-like spines, which are very sharp. The plant is biennial with us in England, and in cold winters is frequently killed. It flowers and seeds about the same time with the former sort, and may be treated in the same way as the Endive.

The broad leaved Succory or Endive, differs from the wild sorts in its duration, the root always perishing after it has ripened seeds: the leaves are broader, rounder at the top, and not lacinated on the sides as the leaves of the wild; the branches are more horizontal, and the stalks never rise so high.

This sort is not much cultivated in the English gardens at present, for the curled Endive being tenderer, and not so bitter, is generally preferred to it. The broad-leaved and curled Endive has been supposed to be only varieties from each other, which hath accidentally been produced by culture; but from having cultivated both near forty years, I could never find that they ever altered, otherwise than by the curled sort coming more or less curled; the leaves of this sort have only a few slight indentures on their edges, and the stalks grow more erect, having but few leaves upon them. This, when blanched, has a bitter taste, which has occasioned its being generally neglected in England, but in Italy it is still cultivated in their gardens.

All the sorts of Succory are esteemed aperitive and diuretic, opening obstructions of the liver, and good for the jaundice; it provokes urine, and cleanses the urinary passages of slimy humours, which may stop their passage.

The curled Endive is now much cultivated in the English gardens, being one of the principal ingredients in the sallads of autumn and winter, for which purpose it is continued as long as the seasons will permit. I shall therefore give directions for the managing of this plant, so as to have it in perfection during the autumn and winter months.

The first season for sowing of these seeds is in May, for those which are sown earlier in the year, generally run up to seed, before they have arrived to a proper size for blanching; and it frequently happens, that the seeds sown in May in the rich ground near London, will run to seeds the same autumn; but in situations which are colder, they are not so apt to run up, therefore there should be some seeds sown about the middle or latter end of that month. The second sowing should be about the middle of June, and the last time in the middle of July. From these three different crops, there will be a supply for the table during the whole season; for there will be plants of each sowing, very different in their growth, so that there

there will be three different crops from the same beds.

When the plants come up they must be kept clean from weeds, and in dry weather duly watered, to keep them growing till they are fit to transplant, when there should be an open spot of rich ground prepared to receive the plants, in size proportionable to the quantity intended. When the ground is well dug and levelled, if it should be very dry, it must be well watered to prepare it to receive the plants; then the plants should be drawn up from the seed-bed carefully, so as not to break their roots, drawing out all the largest plants, leaving the small ones to get more strength; which, when they have room to grow, by taking away the large ones, they will soon do.

As the plants are drawn up, they should be placed with their roots even, all the same way, and every handful as they are drawn, should have the tops of their leaves shortened, to make them of equal length: this will render the planting of them much easier, than when the plants are promiscuously mixed, heads and tails: then the ground should be marked out in rows at one foot asunder, and the plants set ten inches distant in the rows, closing the earth well to their roots, and let them be well watered; and repeat this every other evening, till the plants have taken good root, after which they must be kept clean from weeds.

When the plants of the seed-bed have been thus thinned, they should be well cleaned from weeds and watered, which will encourage the growth of the remaining plants, so that in ten days or a fortnight after, there may be another thinning made of the plants, which should be transplanted in the same manner. And at about the same distance of time, the third and last drawing of plants may be transplanted.

Those plants which were the first transplanted, will be fit to blanch by the latter end of July at farthest; and if they are properly managed, in three weeks or a month, they will be sufficiently blanched for use, which will be as soon as these fallads are commonly required; for during the continuance of good Cos Lettuce, few persons care for Endive in their fallads; nor, indeed, is it so proper for warm weather. If any of the plants should put out flower-stems, they should be immediately pulled up and carried away, being good for nothing, so should not be left to incommode the neighbouring plants. As the quantity of roots necessary for the supply of a middling family is not very great, so there should not be too many plants tied up to blanch at the same time, therefore the largest should be first tied, and in a week after those of the next size; so that there may be three different times of blanching the plants, on the same spot of ground. But as in some large families there is a great consumption of this herb for soups, so the quantities of plants should be proportionably greater, at each time of planting and blanching. The manner of blanching is the next thing to be treated of, therefore in order to this you should provide a parcel of small Osier twigs (or bals mat) to tie up some of the largest heads to blanch; which should be done in a dry afternoon, when there is neither dew nor rain to moisten the leaves in the middle of the plants, which would occasion their rotting soon after their being tied up. The manner of doing it is as follows, viz. You must first gather up all the inner leaves of the plant in a regular order, into one hand, and then take up those on the outside that are sound, pulling off and throwing away, all the rotten and decayed leaves which lie next the ground; observing to place the outside leaves all round the middle ones, as near as possible to the natural order of their growth, so as not to cross each other: then having got the whole plant close up in your hand, tie it up with the twig, bals, &c. at about two inches below the top, very close; and about a week after go over the plants again, and give them another tie about the middle of the plant, to prevent the heart leaves from

bursting out on one side; which they are subject to do; as the plants grow, if not prevented this way.

In doing of this you need only tie up the largest plants first, and so go over the piece once a week, as the plants increase in their growth; by which means you will continue the crop longer, than if they were all tied up at one time: for when they are quite blanched, which will be in three weeks or a month after tying, they will not hold sound and good above ten days or a fortnight, especially if the season proves wet: therefore it is that I would advise to sow at three or four different seasons, that you may have a supply as long as the weather will permit. But in order to this, you must transplant all the plants of the last sowing under warm walls, pales, or hedges, to screen the plants from frost; and if the winter should prove very sharp, you should cover them with some Pease haulm, or such other light covering, which should be constantly taken off in mild weather: these borders should also be as dry as possible, for these plants are very subject to rot, if planted in a moist soil in winter.

Although I before directed the tying up of the plants to blanch them, yet this is only to be understood for the two first sowings; for after October, when the nights begin to be frosty, those plants which are so far above ground will be liable to be much prejudiced thereby, especially if they are not covered in frosty weather; therefore the best method is, to take up your plants of the latter sowings in a very dry day, and with a large flat-pointed dibble, plant them into the sides of trenches of earth, which should be laid very upright, planting them sideways, on the fourth side of the trenches, towards the sun, with the tops of the plants only out of the ground, so that the heavy rains may run off, and the plants be kept dry, and secured from frosts.

The plants thus planted, will be blanched fit for use in about a month or five weeks time, after which it will not keep good more than three weeks, before it will decay; you should therefore continue planting some fresh ones into trenches every fortnight or three weeks, that you may have a supply for the table; and those which were last transplanted out of the seed beds, should be preserved till February, before they are planted to blanch; so that from this you may be supplied until the beginning of April, or later: for at this last planting into the trenches, it will keep longer than in winter, the days growing longer; and the sun, advancing with more strength, dries up the moisture much sooner than in winter, which will prevent the rotting of these plants; but if the weather should prove frosty, these latter plantations of Endive should be covered with mats and straw to preserve it, otherwise the frost will destroy it, but the coverings must always be taken off when the weather is favourable.

When your Endive is blanched enough for use, you must dig it up with a spade; and after having cleared it from all the outside green and decayed leaves, you should wash it well in two or three different waters to clear it the better from slugs, and other vermin, which commonly shelter themselves amongst the leaves thereof, and then you may serve it up to the table with other fallading.

But in order to have a supply of good seeds for the next season, you must look over those borders where the last crop was transplanted, before you put them into the trenches to blanch; and make choice of some of the largest, soundest, and most curled plants, in number according to the quantity of seeds required: for a small family, a dozen of good plants will produce seeds enough; and for a large, two dozen or thirty plants.

These should be taken up and transplanted under a hedge or pale, at about eighteen inches distance, in one row about ten inches from the hedge, &c. This work should be done in the beginning of March, if the season is mild, otherwise it may be deferred a fortnight

fortnight longer. When the flower-stems begin to advance, they should be supported with a packthread, which should be fastened to nails driven into the pale, or to the stakes of the hedge, and run along before the stems, to draw them upright close to the hedge or pale, otherwise they will be liable to break with the strong winds. Observe also to keep them clear from weeds, and about the beginning of July your seeds will begin to ripen; therefore, as soon as you find the seeds are quite ripe, you must cut off the stalks, and expose them to the sun upon a coarse cloth to dry; and then beat out the seeds, which must be dried, and put up in bags of paper, and preserved for use in some dry place. But I would here caution you, not to wait for all the seeds ripening upon the same plant; for if so, all the first ripe and best of the seeds will scatter and be lost before the other are near ripe; so great a difference is there in the seeds of the same plant being ripe.

The wild Succory (of which there are some varieties in the colour of the flowers) is seldom propagated in gardens; it growing wild in unfrequented lanes and dunghills in divers parts of England, where the herb women gather it, and supply the markets for medicinal use.

CICUTA properly signifies an hollow intercepted between two knots, of the stalks or reeds of which the shepherds used to make their pipes, as Virgil sings;

*Est mihi disparibus septem compacta Cicutis
Fistula—*

CICUTA. Lin. Gen. Plant. 316. Sium. Raii Syn. 212. Water Hemlock.

The CHARACTERS are,

It is a plant with an umbellated flower; the principal umbel is composed of several smaller (called rays;) these are equal, roundish, and bristly: the great umbel hath no involucre, but the smaller have, which are composed of many short leaves. The flowers have each five oval petals nearly equal, which turn inward; they have five hairy stamina, which are longer than the petals, terminated by single summits. The germen is situated below the flower, supporting two slender styles, which are permanent and longer than the petals, crowned by stigmas in form of a head. The germen afterward becomes a roundish channelled fruit dividing into two parts, containing two oval seeds, plain on one side and convex on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class of plants, intitled Pentandria Digynia, the flower having five stamina and two styles. The title of this genus has been generally applied to the common Hemlock, which grows naturally on the banks by highways, in most parts of England. But to that plant Dr. Linnæus has applied the old title of Conium, and added this title to the poisonous Water Hemlock described by Webber.

The SPECIES are,

1. **CICUTA** (*Virosa*) umbellis oppositis foliis, petiolis marginatis. Lin. Sp. Plant. 255. Hemlock with umbels opposite to the leaves, and obtuse margined foot-stalks. Sium erucæ folio. C. B. P. 154. Sium with a Rocket leaf. Cicuta aquatica Gesneri. J. B. 111. 2. p. 175. Water Hemlock of Gesner.
2. **CICUTA** (*Maculata*) foliorum serraturis mucronatis, petiolis membranaceis, apice bilobis. Lin. Sp. Plant. 256. Hemlock with pointed serratures to the leaves, and membranaceous foot-stalks ending in two lobes. Angelica Virginiana foliis acutioribus, semine striato minore, cumini sapore & odore. Mor. Hist. 3. p. 281. Virginia Angelica with pointed leaves, and a small channelled seed, having the taste and smell of Cumin.
3. **CICUTA** (*Bulbifera*) ramis bulbiferis. Lin. Sp. 367. Hemlock, whose branches bear bulbs. Ammi foliorum lacinulis capillaribus, caule angulato. Flor. Virg. 31. The first sort grows naturally in standing waters in many parts of England, so is never propagated in gardens; for unless there is a considerable depth of

standing water for the plants to root in; they will not grow. I have several times transplanted these plants into ponds, where they have grown one summer, but have not continued through the winter.

It grows near four feet high, with a branching hollow stalk, garnished with winged leaves. The stalks are terminated by umbels of yellowish flowers, which are succeeded by small channelled seeds like those of Parsley. It flowers in June and July, and the seeds ripen in autumn.

The second sort grows naturally in North America, from whence the seeds have been brought to England, where the plants are preserved in botanic gardens for the sake of variety. This is propagated by seeds, which should be sown in autumn in a shady border, where the plants will come up in the spring, and require no other care but to keep them clean.

The third sort is a native of North America. This is sometimes preserved in botanic gardens for variety, but being a plant of no great beauty or use, is seldom allowed a place in other gardens. It is propagated by seeds, which should be sown in autumn, and the plants afterward treated as those of the second sort.

CICUTARIA. See **LIGUSTICUM**.

CINARA. See **CYNARA**.

CINERARIA, Sea Ragwort.

The CHARACTERS are,

It has a simple empalement, composed of many small equal leaves. The flower is radiated. The disk is composed of many hermaphrodite florets, which are funnel-shaped, cut into five segments at the top; these have five slender stamina, crowned by cylindrical summits, and an oblong germen, supporting a very slender style, crowned by two erect stigmas. The germen afterward becomes a narrow four-cornered seed, covered with downy hairs. The female florets which compose the rays are tongue-shaped, indented at their points; these have an oblong germen with two styles, and have seeds like the hermaphrodite florets, which are included in the empalement.

This genus of plants is ranged in the second order of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua, the flowers being composed of hermaphrodite and female florets, which are both fruitful.

The SPECIES are,

1. **CINERARIA** (*Geifolia*) pedunculis ramosis, foliis reniformibus suborbiculatis sublobatis dentatis petiolatis. Lin. Sp. 1242. Ragwort with branching foot-stalks, kidney-shaped, orbicular, indented leaves upon foot-stalks. Jacobæa Africana, hederæ terrestris folio, repens. Hort. Amst. 2. p. 145.
2. **CINERARIA** (*Maritima*) floribus paniculatis, foliis pinnatifidis tomentosis, laciniis sinuatis, caule frutescente. Lin. Sp. 1244. Sea Ragwort with a shrubby stalk, woolly wing-pointed leaves, and flowers growing in panicles. Jacobæa maritima. C. B. P. 131. Sea Ragwort.
3. **CINERARIA** (*Ameloides*) pedunculis unifloris, foliis ovatis oppositis, caule suffruticoso. Lin. Sp. 1245. Ragwort with an under shrub stalk, oval leaves placed opposite, and foot-stalks with one flower. After caule ramoso scabro perenne, foliis ovatis sessilibus, pedunculis nudis unifloris. Fig. pl.
4. **CINERARIA** (*Othonnites*) pedunculis unifloris, foliis oblongis indivisis subdentatis petiolatis alternis nudis. Lin. Sp. 1244. Ragwort with oblong undivided leaves slightly indented, and foot-stalks with one flower. Jacobæa Africana frutescens, crassis & succulentis foliis. Hort. Amst. 2. p. 147.
5. **CINERARIA** (*Tomentosa*) foliis pinnato-sinuatis dentatis subtus tomentosis, floribus paniculatis, caule frutescente. Ragwort with sinuated, wing-shaped, indented leaves, downy on their under side, flowers in panicles, and a shrubby stalk. Jacobæa maritima latifolia. C. B. P. 69.

There are several other species of this genus than are here enumerated, but being plants of little use or beauty are omitted, as they are rarely cultivated in gardens.

The

C I R

The first sort grows naturally at the Cape of Good Hope. The root of this is composed of many small fibres; the stalks are weak, so trail on the ground, if they are not supported; but if they are will rise four feet high, dividing into many branches, garnished with roundish kidney-shaped leaves, crenated on their edges; the flowers are produced at the extremity of the branches in small clusters; they are yellow, and in shape like those of the common Ragwort, which are succeeded by seeds, crowned with down.

This sort is easily propagated by cuttings, which, if planted in a shady border during the summer months, and duly watered, will put out roots in a month or five weeks; soon after which it will be proper to transplant them into pots, because their roots are very apt to spread in the full ground; so when the plants are taken up, many of their roots are torn off, whereby the plants are endangered. This is also often the case of the plants in pots. When they are not often removed, their roots will shoot through the holes in the bottom of the pots into the ground, and the plants will grow luxuriantly; but when the pots are removed, and those roots torn off, the plants are often killed thereby. As this plant grows naturally at the Cape of Good Hope, it is too tender to live through the winters in England in the open air; yet if it is nursed tenderly, it is very apt to draw up weak, and thereby is destroyed; therefore the surest method to preserve it, is to make young plants annually from cuttings, and to place them in a common hot-bed frame in winter, where they may enjoy the full air in mild weather, but be screened from the frost, and in summer place them abroad with other of the hardier sorts of exotic plants.

The second sort grows naturally on the sea-coasts in some parts of England and Wales, in particular warm spots, but in the south of France and Italy, it is very common. This hath many ligneous stalks, which rise two or three feet high, dividing into many branches, which have a white downy bark, and are garnished with very woolly leaves six or eight inches long, deeply sinuated, and jagged on their borders into many winged points; they are downy on both sides. The stalks which support the flowers are a foot or more in length, having two or three small leaves on each, shaped like those below, and are terminated by many yellow flowers growing in panicles, shaped like those of common Ragwort; these appear in June, July, and August, and are succeeded by seeds, which ripen the beginning of October.

This sort is also easily propagated by planting cuttings or slips of it on a shady border during the summer months, observing to water them duly. When these are well rooted, they should be planted in a dry rubbishing soil, where they will resist the cold of our ordinary winters very well, and continue many years; but in rich moist ground, the plants are often so very luxuriant in summer, as to be killed in winter when there is much frost.

The third sort grows naturally at the Cape of Good Hope. This hath branching stalks, which are shrubby, and rise from two to three feet high, garnished with oval leaves placed opposite: the foot-stalks of the flowers are long, naked, and support one blue flower at the top, whose rays are reflexed; these appear great part of the year, and those which blow in summer are succeeded by compressed seeds crowned with down.

This may be propagated by sowing the seeds on a bed of light earth the beginning of April, and when the plants are fit to remove, they should be part of them planted in pots, that they may be sheltered in winter under a hot-bed frame; the remainder may be planted close to a warm wall in poor ground, where, if the winter proves favourable, they will live; but if these fail, those in the frame will be secured. It may also be propagated by cuttings, in the same manner as the last mentioned.

The fourth sort hath shrubby branching stalks, which

C I R

rise three or four feet high, garnished with oblong, thick, undivided leaves, of a glaucous colour. The flowers are produced on branching foot-stalks, arising toward the end of the branches; they are yellow, shaped like those of the other sorts, but are rarely succeeded by seeds in England. This is easily propagated by cuttings any time in summer: the plants, when rooted, must be planted in pots, that they may be removed into shelter in winter, for they will not live abroad in England. It grows naturally at the Cape of Good Hope.

The fifth sort grows naturally on the sea coasts of Italy and Sicily. This has great resemblance to the second sort, but the stalks are more woody, rise higher, and do not branch so much. The leaves are broader, not so much sinuated, and are of a black green colour on their upper side. The flowers are produced in smaller bunches on the top of the foot-stalks, and are like those of the second sort, but are rarely succeeded by seeds in England, nor are the plants so hardy, therefore should be sheltered in winter. It is easily propagated by cuttings during the summer months, in the same way as the second sort.

CIRCEA. Lin. Gen. Plant. 24. Tourn. Inst. R. H. 301. tab. 155. [It is said to be so called from Circe, the famous enchantress, said to have enchanted Ulysses and his companions. Boerhaave supposes it to be so called, because the fruit of this plant takes hold of peoples cloaths, and by this means draws them to it, as the enchantress Circe was wont to do by her enchantments.] Enchanter's Nightshade.

The CHARACTERS are,

The empalement of the flower is composed of two oval concave leaves: the flower hath two heart-shaped petals, which are equal and spread open; it hath two erect hairy stamina, terminated by roundish summits. The germen is situated under the flower, supporting a slender style, crowned by an obtuse bordered stigma. The empalement afterward becomes a rough oval capsule with two cells opening lengthways, each containing a single oblong seed.

This genus of plants is ranged in the first section of Linnæus's second class, intitled Diandria Monogynia, the flower having two stamina and one style.

The SPECIES are,

1. CIRCEA (*Lutetiana*) caule erecto, racemis pluribus. Lin. Sp. Plant. 9. *Enchanter's Nightshade, with an upright stalk and many spikes of flowers.* Circea lutetiana. Lob. Icon. 266. *Common Enchanter's Nightshade.*
2. CIRCEA (*Alpina*) caule adscendente, racemo unico. Lin. Sp. Plant. 9. *Enchanter's Nightshade, with an ascending stalk and a single spike.* Circea minima. Col. p. 2. 80. *Least Enchanter's Nightshade.*

The first sort grows naturally in shady woods, and under hedges, in many parts of England. This plant hath a creeping root, by which it multiplies greatly. The stalks are upright, and rise a foot and a half high, garnished with heart-shaped leaves placed opposite, upon very long foot-stalks: these are of a dark green on their upper side, but are pale on their under side. The stalks are terminated by loose spikes of flowers, which are branched out into three or four small spikes. The flowers are small and white, having but two petals, opposite to which are situated the two stamina. After the flowers fall away, the empalement of the flower becomes a rough capsule, inclosing two oblong seeds.

The second sort grows at the foot of mountains in many parts of Germany. It also grows naturally in a wood near the Hague, from whence I brought it to England. This sort seldom rises more than six or eight inches high, with a slender stalk, garnished with leaves shaped like those of the former sort, but smaller, and are indented on their edges. The flowers are produced on single loose spikes at the top of the stalks, which are smaller than those of the former sort, but of the same form and colour. These plants flower in June, and their seeds ripen in August; but they both multiply exceedingly by their creeping

roots, so are seldom kept in gardens, unless for the sake of variety.

If the roots are planted in any shady moist part of a garden, they will increase fast enough without any care.

CIRCULATION of the sap. See **SAP**.

CIRRI are those fine strings or fibres put out from the stalks of plants, by which some plants fasten themselves to walls, pales, or trees, in order to their support, as Ivy, &c.

CIRSIIUM. See **CARDUUS**.

CISSAMPELOS. Lin. Gen. Plant. 993. *Caapeba*. Plum. Nov. Gen. 33. tab. 29.

The **CHARACTERS** are,

It is male and female in different plants; the male flowers have no empalement; they have four oval plain petals, and a wheel-shaped nectarium in the disk, with four small stamina joined together, crowned by plain summits. The female flowers have neither empalement or corolla; instead of petals, there is a large nectarium, whose membranes stand round the hairy oval germen, which afterward becomes a succulent berry, inclosing a single seed.

This genus of plants is ranged in the twelfth section of Linnaeus's twenty-second class, intitled *Diœcia Monodelphia*, the male and female flowers being on different plants, and the male flowers have four stamina, which are joined in one body.

The **SPECIES** are,

1. **CISSAMPELOS** (*Pariera*) foliis peltatis cordatis emarginatis. Lin. Sp. 1473. *Cissampelos* with target heart-shaped leaves which are indented at their top. *Caapeba* folio orbiculari, & umbilicato lævi. Plum. Nov. 33. *Caapeba* with a round, smooth, umbilicated leaf.

2. **CISSAMPELOS** (*Caapeba*) foliis basi petiolatis integris. Lin. Sp. 1473. *Cissampelos* with leaves having foot-stalks, and entire at their base. *Caapeba* folio orbiculari non umbilicato. Plum. Nov. Gen. 33. *Caapeba* with a round leaf not umbilicated, called *Velvet Leaf* in America.

These plants grow naturally in the warmest parts of America, where they twist themselves about the neighbouring shrubs, and rise to the height of five or six feet. The first sort hath round heart-shaped leaves, whose foot-stalks are set within the base of the leaf, resembling an ancient target; these are hairy on their under side, and have pretty long slender foot-stalks. Toward the upper part of the stalks the flowers come out from the wings of the leaves; those of the male plants grow in short spikes or clusters, and are of a pale herbaceous colour; but the female flowers are produced in long loose racemi from the side of the stalks, and are succeeded by a single pulpy berry inclosing a single seed.

The second sort hath round heart-shaped leaves, which are extremely woolly and soft to the touch; these have their foot-stalks placed at the base between the two ears; the flowers of this come out in bunches from the side of the stalks, in the same manner as the first. The stalks and every part of the plant is covered with a soft woolly down.

The seeds of both these plants were sent me from Jamaica, by the late Dr. Houstoun, which succeeded in the Chelsea garden, where the plants produced their flowers for several years; and the fruit of the first sort were produced, but these would not grow, though they seemed to be perfectly ripened; but the plants grew at some distance from the male, so were probably not impregnated.

These plants are propagated by seeds, which should be sown upon a hot-bed in the spring; and the plants must afterward be treated in the same way as other tender exotics, keeping them constantly in the bark-stove, otherwise they will not live in this country.

The first sort is supposed to be the *Pareira*, whose root has been so much esteemed as a diuretic. But by a specimen which I received from the late Dr. Houstoun, under the title of *Pariera*, it should rather be ranged under the genus of *Smilax*.

CISSUS, Wild Grape.

The **CHARACTERS** are,

It hath a small many-leaved empalement, and four concave petals to the flower, with a large nectarium at the border of the germen, and four stamina the length of the corolla inserted in the nectarium, crowned by roundish summits. The germen is four-cornered, supporting a slender style the length of the stamina, crowned by an acute stigma. The cover of the flower afterward becomes a berry inclosing one roundish seed.

This genus of plants is ranged in the first section of Linnaeus's fourth class, intitled *Tetrandria Monogynia*, the flowers having four stamina and one style.

The **SPECIES** are,

1. **CISSUS** (*Cordifolia*) foliis cordatis integerrimis. Lin. Sp. 170. *Wild Grape* with entire heart-shaped leaves. *Vitis* folio subrotundo, uva corymbosa cæruleo. Plum. Gen. 18.
2. **CISSUS** (*Sicyoides*) foliis ovatis nudis fetaceo ferratis. Lin. Sp. 170. *Wild Grape* with oval leaves which are sawed. *Bryonia* alba geniculato, violæ foliis, baccis e viridi-purpurascens. Sloan. Hist. Jam. 1. p. 106.
3. **CISSUS** (*Acida*) foliis ternatis oblongis carnosissimis. Lin. Sp. 170. *Wild Grape* with trifoliate leaves, which are oblong, fleshy, and cut on their edges. *Vitis* trifolia minor corymbosa, acinis nigrioribus turbinate. Plum. Sp. 18.

4. **CISSUS** (*Trifoliata*) foliis ternatis subrotundis subdentatis. Lin. Sp. 170. *Wild Grape* with roundish trifoliate leaves, which are slightly indented. *Bryonia* alba triphylla maxima. Sloan. Hist. Jam. 1. p. 106.

These plants all of them grow naturally in the island of Jamaica, and in some of the other islands in the warm parts of America, where they send out slender branches, having tendrils at their joints, by which they fasten to the neighbouring trees, bushes, and any other support, mounting to a considerable height. The first sort produces bunches of fruit, which are frequently eaten by the negroes, but are chiefly food for birds and wild fowl, as indeed are most of the fruit of the other sorts, as they all grow in the uncultivated parts.

The plants are preserved in some of the European gardens, more for the sake of variety, than for use or beauty, as they rarely produce either fruit or flowers in moderate climates. They are propagated either by laying their flexible branches down in pots of earth, where they will put out roots in four or five months, or by planting cuttings in pots filled with light earth, which should be plunged into a moderate hot-bed of tanners bark, covering the pots closely with hand-glasses to exclude the outer air: the cuttings must be frequently refreshed with water, but not too much given at each time. When these or the layers are well rooted, they should be carefully taken up, and each planted in a small pot filled with light earth, and plunged into the hot-bed of tan, where they should constantly remain, being too tender to thrive in England, but with this care. Therefore they should be shifted into larger pots when it is necessary, and their branches must be supported with stakes, to prevent them from trailing over the neighbouring plants; and in warm weather the plants should have free air admitted to them daily. With this treatment they will thrive very well.

CISTUS. Lin. Gen. Plant. 598. Tourn. Inst. R. H. 259. tab. 136. [It is so called from *Κίστρος*, or *Κιστός*, Gr. Ivy, because its small seminal vessel is inclosed in a cista, or little chest.] *Rock-rose*.

The **CHARACTERS** are,

The flower hath a five-leaved empalement which is permanent, two of the middle alternate leaves being smaller than the other. The flower hath five large roundish petals which spread open; it hath a great number of hairy stamina, which are shorter than the petals, and are terminated by small roundish summits. In the center is situated a roundish germen, supporting a single style the length of the stamina, crowned by a plain orbicular stigma. The germen afterward becomes an oval close capsule, having in some five, and others ten cells, filled with small roundish seeds.

This

C I S

This genus of plants is ranged in the first section of Linnaeus's thirteenth class, intitled Polyandria Monogynia, the flowers having many stamina and but one style.

The SPECIES are,

1. *CISTUS (Pilosus)* arborescens exstipulatus foliis ovatis, petiolatis hirsutis. Lin. Sp. 736. *Tree Rock-rose with oval leaves, whose foot-stalks are hairy. Cistus mas major, folio rotundiore. J. B. 2. 2. Greater male Cistus, or Rock-rose, with a rounder leaf.*
2. *CISTUS (Incanus)* arborescens exstipulatus foliis spatulatis tomentosis rugosis, inferioribus basi vaginantibus connatis. Hort. Cliff. 205. *Tree Rock-rose with spatule-shaped, woolly, rough leaves, which are joined at their base. Cistus mas 2 folio longiore incano. J. B. 2. 2.*
3. *CISTUS (Breviorifolius)* arborescens, foliis ovato-lanceolatis, basi connatis, hirsutis, rugosis, pedunculis florum longioribus. *Tree Rock-rose with oval spear-shaped leaves, joined at their base, which are hairy and rough, and longer foot-stalks to the flowers. Cistus mas folio brevior. C. B. P. 464.*
4. *CISTUS (Lusitanicus)* arborescens, foliis ovatis, obtusis, villosis, subtus nervosis rugosis, floribus amplioribus. *Tree Rock-rose, with oval, obtuse, hairy leaves, which are nervous and rough on their under side, and larger flowers. Cistus mas Lusitanicus, folio amplissimo incano. Tourn. Inst. 259.*
5. *CISTUS (Hispanicus)* arborescens villosus, foliis lanceolatis, viridibus, basi connatis, floribus sessilibus, calycibus acutis. *Hairy-tree Rock-rose with green spear-shaped leaves joined at their base, flowers sitting close, and sharp-pointed empalements.*
6. *CISTUS (Ladaniferus)* arborescens exstipulatus, foliis lanceolatis, supra laevibus, petiolis basi coalitis vaginantibus. Hort. Cliff. 205. *Tree Rock-rose with spear-shaped leaves, smooth on their upper side, and their foot-stalks joining like sheaths. Cistus ladanifera Hispanica incana. C. B. P. 467.*
7. *CISTUS (Albidus)* arborescens exstipulatus foliis ovato-lanceolatis tomentosis incanis, sessilibus subtrinerviis. Sauv. Monsp. 150. *Tree Rock-rose with oval, spear-shaped, woolly leaves, sitting close to the stalks. Cistus mas folio oblongo incano. C. B. P. 464.*
8. *CISTUS (Salvifolius)* arborescens exstipulatus, foliis ovatis petiolatis utrinque hirsutis. Hort. Cliff. 205. *Rock-rose with oval hairy leaves, having foot-stalks. Cistus foemina, folio salviae, supina humisparfa. C. B. P. 466.*
9. *CISTUS (Creticus)* arborescens exstipulatus, foliis spatulato-ovatis petiolatis enerviis scabris, calycinis lanceolatis. Lin. Sp. 738. *Tree Rock-rose with oval spatule-shaped rough leaves without veins, having foot-stalks. Cistus ladanifera Cretica flore purpureo. Tourn. Cor. 19. Gum-bearing Cistus of Crete with a purple flower.*
10. *CISTUS (Oleaeifolius)* fruticosus, foliis lineari-lanceolatis, hirsutis, sessilibus, floribus terminalibus. *Shrubby Rock-rose with narrow, spear-shaped, hairy leaves, sitting close to the branches, and flowers terminating the stalks. Cistus ledon foliis oleae sed angustioribus. C. B. P. 167.*
11. *CISTUS (Laurifolius)* arborescens exstipulatus foliis oblongo-ovatis petiolatis, trinerviis supra glabris. *Tree Rock-rose with oblong oval leaves, having foot-stalks, smooth above, and the foot-stalks joined at their base. Cistus ledon foliis laurinus. C. B. P. 476.*
12. *CISTUS (Cordifolius)* foliis oblongo-cordatis, glabris, petiolis longioribus, caule fruticoso. *Rock-rose with oblong, heart-shaped, smooth leaves, longer foot-stalks, and a shrubby stalk.*
13. *CISTUS (Monspeliensis)* arborescens exstipulatus, foliis lineari-lanceolatis, sessilibus, utrinque villosis, trinerviis. Hort. Cliff. 205. *Tree Rock-rose with linear spear-shaped leaves sitting close to the branches, hairy on both sides, having three nerves. Cistus ladanifera Monspeliensum. C. B. P. 467.*
14. *CISTUS (Salicifolius)* arborescens, foliis lineari-lanceolatis, subtus incanis, trinerviis, petalis subrotundis. *Tree Rock-rose with narrow spear-shaped leaves, hoary on their under side, having three nerves with roundish petals. Cistus ladanifera Hispanica, salicis folio, flore*

C I S

albo; maculae puniceae insignito. Tourn. Inst. R. H. 260. *Spanish Gum-bearing Cistus with white flowers spotted with purple.*

15. *CISTUS (Populifolius)* arborescens exstipulatus, foliis cordatis laevibus acuminatis petiolatis. Hort. Cliff. 205. *Tree Rock-rose with heart-shaped smooth leaves, having foot-stalks. Cistus ledon foliis populi nigrae major. C. B. P. 467.*
16. *CISTUS (Crispus)* arborescens exstipulatus, foliis lanceolatis pubescentibus trinerviis undulatis. Hort. Cliff. 206. *Rock-rose with spear-shaped, hairy, waved leaves, having three veins. Cistus mas, foliis chamædryos. C. B. P. 464.*
17. *CISTUS (Halimifolius)* foliis ovatis, incanis, inferne petiolatis, superne coalitis, caule fruticoso. *Rock-rose with oval hoary leaves, those beneath having foot-stalks, and the upper ones joined at their base, and a shrubby stalk. Cistus Halimi, folio 1. Clus. Hist. 1. p. 71. Cistus with Sea Purslane leaves.*
18. *CISTUS (Longifolius)* foliis lineari-lanceolatis, incanis petiolatis, floribus racemosis caule fruticoso. *Rock-rose with narrow spear-shaped leaves, having foot-stalks which are hoary, flowers growing in clusters, and a shrubby stalk. Cistus folio halimi longiore incano. J. B. 2. 5.*

These plants all grow naturally in the south of France, in Spain, and Portugal, from whence their seeds have been brought to England, where most of the sorts are now cultivated in the nurseries for sale. The first sort hath a strong woody stem, covered with a rough bark, which rises three or four feet high, dividing into many branches, so as to form a large bushy head, garnished with oval hairy leaves, placed opposite, and sit close to the branches, having several smaller leaves of the same form, rising from the same joint. The flowers are produced at the end of the branches, four or five standing together, almost in form of an umbel, but rarely more than one is open at the same time; these are composed of five large roundish petals of a purple colour, which spread open like a Rose, having a great number of stamina, surrounding the oval germen in the center, terminated by small, roundish, yellow summits; these flowers are but of short duration, generally falling off the same day they expand; but there is a succession of fresh flowers every day for a considerable time. After the flowers are past, the germen swells to an oval seed-vessel, sitting in the empalement, which is hairy; these capsules have ten cells, which are full of small roundish seeds. This sort flowers in May and June, and the seeds ripen in autumn; and there is generally more flowers produced in September and October, if the autumn proves favourable, and where the plants are protected from frost, they frequently produce some flowers all the winter season.

The second sort differs from the first in the shape of the leaves, which are longer and whiter; those on the lower part of the branches are oval, and join at their base, surrounding the stalks, but the upper leaves are spear-shaped and distinct; the flowers are larger, and of a paler purple colour. This flowers and ripens seeds at the same time with the first.

The third sort differs from both the former, in having shorter and greener leaves, which are joined at their base, and are hairy. The foot-stalks of the flowers are much longer, and the flowers are smaller, but of a deeper purple. This flowers and seeds at the same time with the two former, and the shrubs grow as large as the first sort.

The fourth sort hath much larger and rounder leaves than either of the former, which are hairy, and smooth on their upper side, but rough, and full of veins on their under; the branches are white, hairy, and the flowers are very large, and of a light purple colour. This flowers at the same time with the former.

The fifth sort doth not rise so high as either of the former, but sends out branches near the root, which are hairy and erect, garnished with spear-shaped leaves, of a dark green colour, which join at their base,

base, surrounding the stalk. At each joint comes out a very slender branch, having three pair of small leaves of the same shape with the other, terminated by a single flower; the ends of the branches have three or four flowers sitting close without foot-stalks. The flowers are of a deep purple colour, and like those of the first. This flowers at the same time with the other sorts.

The sixth sort rises to the height of five or six feet, with a strong woody stalk, sending out many hairy branches, garnished with spear-shaped leaves, smooth on their upper side, but veined on their under, having short foot-stalks, which join at their base, where they form a sort of sheath to the branch. The flowers come out at the end of the branches, which are large, of a light purple colour, and resembling those of the fourth sort.

The seventh sort hath erect branches, which come out from the lower part of the stalk, and are woolly; garnished with oblong hoary leaves, covered with a white down, which are smooth above, but veined on their under side, joining at their base where they surround the stalk; the flowers are produced at the end of the branches, which are of a bright purple colour, and large. This flowers at the same time with the other sorts.

The eighth sort hath a slender smooth stalk, covered with a brown bark, which never rises more than three feet high, sending out many horizontal weak branches, which spread wide, garnished with small oval leaves, which are hairy, standing upon short foot-stalks. The flowers come out at the wings of the leaves, upon long naked foot-stalks; these are white, and somewhat smaller than those of the other sorts. This flowers in June, July, and August.

The ninth sort grows naturally in the islands of the Archipelago; this is the plant which produces the labdanum, as is hereafter mentioned; it rises three or four feet high, with a woody stalk, sending out many lateral branches, covered with a brown bark, garnished with oval, spear-shaped, hairy leaves, with waved borders; these in warm seasons sweat a glutinous liquid, which spreads on the surface of the leaves, is very clammy and sweet scented. The flowers come out at the end of the branches, on short hairy foot-stalks; they are of a deep purple colour, and about the size of a single Rose; these appear in June and July.

The tenth sort rises with a shrubby stalk about four feet high, the branches are very hairy, glutinous, grow erect, and are garnished with long, narrow, hairy leaves, ending in points, of a deep green on both sides, having a deep longitudinal furrow on their upper side, made by the midrib, which is prominent, the flowers stand upon long foot-stalks at the end of the branches, which are of a pale sulphur colour, having a bordered empalement, which is cut into five acute parts at the top. This flowers in June, July, and August, and the seeds ripen in autumn.

The eleventh sort rises with a strong woody stem to the height of five or six feet, sending out many erect branches, garnished with spear-shaped leaves ending in points; these are thick, white on their under side, of a dark green above, and very glutinous in warm weather. The flowers are produced at the end of the branches, upon long naked foot-stalks, which branch on their sides into small foot-stalks, each sustaining one large white flower, having a hairy empalement. This sort flowers in June and July.

The twelfth sort rises with a smooth shrubby stalk four or five feet high, sending out many slender ligneous branches, covered with a smooth brown bark; garnished with oblong heart-shaped leaves, which are smooth, and have long foot-stalks. The flowers are produced at the end of the branches, standing upon pretty long foot-stalks; they are white, and appear in June, July, and August, but rarely produce any seeds in England.

The thirteenth sort rises with a slender shrubby stalk, from three to four feet high, sending out many

branches from the bottom upward, which are hairy, garnished with spear-shaped leaves, of a very dark green colour, having three longitudinal veins in each, and in warm weather are covered with a glutinous sweet-scented substance, which exudes from their pores. The flower-stalks which come out at the end of the branches, are long, naked, and sustain many white flowers, rising above each other; their empalements are bordered, and end in sharp points. This flowers at the same time with the last mentioned.

The fourteenth sort rises with a woody stem to the height of five or six feet, sending out many side branches from the bottom, the whole length; these are smooth, covered with a reddish brown bark, garnished with narrow spear-shaped leaves, whitish on their under side, of a dark green above, having three longitudinal veins. The flowers are produced at the end of the branches, on short foot-stalks, and are composed of five very large, roundish, white petals, each having a large purple spot at their base. The whole plant exudes a sweet glutinous substance in warm weather, which hath a very strong balsamic scent, so as to perfume the circumambient air to a great distance. This flowers in June, July, and August.

There is a variety of this with white flowers, having no purple spots, which is in all other respects the same with this.

The fifteenth sort hath a stiff, slender, woody stalk, which sends out many branches the whole length, and rises to the height of six or seven feet; the leaves are large, heart-shaped, and of a light green colour; these sit close to the branches, having many nerves; the flowers are produced at the end of the branches, upon naked foot-stalks; they are white, and soon drop off. This flowers in June and July, and is at present pretty rare in the English gardens.

The sixteenth sort hath weak, slender, woody branches, which spread horizontally, so seldom rise more than two or three feet high, garnished with spear-shaped hairy leaves, which are indented on their edges, and have three longitudinal veins running through them; the flowers are white, coming out upon naked foot-stalks from the wings of the leaves; these are succeeded by roundish blunt seed-vessels, having several cells, filled with angular seeds. This flowers in June and July, and the seeds ripen in August and September.

The seventeenth sort hath an upright shrubby stalk, which rises four or five feet high, sending out many branches from the ground upward, so as to form a large bush. The branches are channelled and hoary. The leaves are oval, standing opposite; those on the lower part of the branches have foot-stalks, but upward they coalesce at their base, and surround the stalk; they are very white. The foot-stalks of the flowers which rise at the end of the branches, are a foot in length, naked, hairy, and put out two or four shorter foot-stalks on the side, each supporting three or four flowers. The flowers are large, of a bright yellow colour, but of short duration; their empalements are hairy, and sharp-pointed. This flowers in June and July, and at present is but in few English gardens.

The eighteenth sort hath been long preserved in the English gardens; this rises with a slender woody stalk three or four feet high, sending out many slender branches, garnished with narrow, spear-shaped, hoary, waved leaves; from the wings of the leaves come out slender branches, which have two or three pair of small leaves, terminated by loose bunches of flowers, each standing on a slender foot-stalk. The flowers are of a dirty sulphur colour, and appear in June and July, but are never succeeded by seeds in this country.

This sort will not live abroad in the winter, so is always placed in a green-house, where, by its hoary leaves, which continue all the year, it makes a variety.

All the various kinds of *Cistus* are very great ornaments to a garden; their flowers are produced in great plenty, which though but of a short duration, yet are succeeded by fresh ones almost every day for above two months successively; these flowers are many of them about the bigness of a middling Rose, but single, and of different colours; the plants continue their leaves all the year.

These plants are all of them, except the last, hardy enough to live in the open air in England, unless in very severe winters, which often destroys many of them, so that a plant or two of each sort may be kept in pots, and sheltered in winter, to preserve the kinds; the rest may be intermixed with other shrubs, where they will make a pretty diversity; and in such places where they are sheltered by other plants, they will endure the cold much better than where they are scattered singly in the borders. Many of these plants will grow to the height of five or six feet, and will have large spreading heads, provided they are permitted to grow uncut; but if they are ever trimmed, it should be only so much as to prevent their heads from growing too large for their stems; for whenever this happens, they are apt to fall on the ground, and appear unightly.

These shrubs are propagated by seeds, and also from cuttings; but the latter method is seldom practised, unless for those sorts which do not produce seeds in England; these are the twelfth, seventeenth, and eighteenth sorts; all the others generally produce plenty of seeds, especially those plants which came from seeds; for those which are propagated by cuttings, are very subject to become barren, which is also common to many other plants.

The seeds of these plants may be sown in the spring upon a common border of light earth, where the plants will come up in six or seven weeks, and, if they are kept clear from weeds, and thinned where they are too close, they will grow eight or ten inches high the same year; but as these plants, when young, are liable to injury from hard frost, therefore they should be transplanted when they are about an inch high, some into small pots filled with light earth, that they may be removed into shelter in winter, and the others into a warm border, at about six inches distance each way; those which are potted, must be set in a shady situation till they have taken new root; and those planted in the border must be shaded every day with mats till they are rooted, after which the latter will require no other care but to keep them clean from weeds till autumn, when they should have hoops placed over them, that they may be covered in frosty weather; those in the pots may be removed into an open situation, so soon as they have taken new root, where they may remain till the end of October, but during the summer they must be shifted into larger pots, and be frequently watered; the end of October they should be placed under a hot-bed frame to screen them from the cold in winter, but, at all times, when the weather is mild, they should be fully exposed to the open air, and only covered in frosts: with this management, the plants will thrive much better than when they are more tenderly treated.

The above method is what the gardeners generally practise; but those who are desirous to have their plants come forward, should sow the seeds on a moderate hot-bed in the spring, which will bring up the plants very soon; but these must have plenty of air when they appear, otherwise they will draw up very weak; when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into a very moderate hot-bed, observing to shade them till they have taken fresh root; then they must have plenty of air admitted to them every day in good weather, to prevent their drawing up weak; and by degrees they must be hardened, so as to be removed into the open air the beginning of June, and then they may be treated in the same manner as is before directed for the other seedling plants. By the bringing

of the plants forward in the spring in this method, they will grow to the height of two feet, or more, the first summer, and have many lateral branches, so will be strong enough to plant abroad the following spring, and most of them will flower the same summer; whereas those which are sown in the full ground, rarely flower till the year after; nor will they be so strong, or capable to resist the cold of the second winter, as those which have been brought forward.

In the spring following, these plants may be turned out of the pots, with all the earth preserved to their roots, and planted in the places where they are to remain (for they are bad plants to remove when grown old,) observing to give them now and then a little water, until they have taken fresh root; after which time, they will require no farther care than to train them upright in the manner you would have them grow; but those plants which were at first planted into a border in the open ground, should be arched over, and covered with mats in frosty weather, during the first winter, but may be transplanted abroad the succeeding spring. In removing of these plants, you should be careful to preserve as much earth about the roots as you can; and if the season should prove hot and dry, you must water and shade them until they have taken fresh root, after which they will require no other culture than was before directed.

These plants may also be propagated by cuttings, which should be planted in May or June, upon a bed of light earth, keeping them shaded with mats, and frequently refreshed with water, until they have taken root; which will be in about two months time, when you may transplant them into pots filled with good fresh light earth, and they should be set in a shady place until they have taken root, then they may be exposed to the open sun until October, when you should remove them into shelter the first winter; but the succeeding spring you may plant them abroad, as was before directed for the seedling plants.

The fourteenth and fifteenth sorts are by much the most beautiful of all these *Cistus*'s; the flowers, which are as big as a large Rose, are of a fine white, with a deep purple spot on the bottom of each leaf. These plants also abound with a sweet glutinous liquor, which exudes through the pores of the leaves in so plentiful a manner in hot weather, that the surfaces of the leaves are covered therewith; from this plant *Clusius* thinks might be gathered great quantities of the *ladanum* which is used in medicine, in the woods in Spain, where he saw vast quantities of this shrub growing.

But it is from the ninth sort, which *Monf. Tournefort* says, the Greeks, in the Archipelago, gather this sweet gum; in the doing of which (*Bellonius* says) they make use of an instrument like a rake without teeth, which they call *ergastiri*; to this are tied many thongs of raw and untanned leather, which they rub gently on the bushes that produce *ladanum*, so that the liquid moisture may stick upon the thongs, after which they scrape it off with knives; this is done in the hottest time of the day, for which reason the labour of gathering this *ladanum* is excessive, and almost intolerable, since they are obliged to remain on the mountains for whole days together, in the very heat of summer, or the dog days; nor is there any person almost that will undertake this labour, except the Greek monks.

Monf. Tournefort also relates the same in his travels, where he says, that the shrubs which produce the *ladanum* grow upon dry sandy hillocks; and that he observed several country fellows in their shirts and drawers, that were brushing the shrubs with their whips; the straps whereof, by being drawn over the leaves of the plant, licked up a sort of odoriferous balsam sticking upon the leaves, which he supposes to be part of the nutritious juice of the plant, which exudes through the pores of the leaves, where it remains like a fattish dew, in shining drops as clear as turpentine.

When the whips are sufficiently laden with this greafe, they take a knife, and scrape it clean off the straps, and make it up into a mass of cakes of different sizes; this is what comes to us under the name of ladanum, or labdanum. A man that is diligent, will gather three pounds two ounces per day, or more, which they sell for a crown on the spot; this work is rather unpleasant than laborious, because it must be done in the hottest time of the day, and in the greatest calm; and yet the purest ladanum is not free from filth, because the winds of the preceding days have blown dust upon these shrubs, which, by the glewy substance upon the surfaces of the leaves, is thereby detained and mixed therewith. But to add weight to this drug, they knead it up with a very fine blackish sand, which is found in those parts, as if nature herself was minded to teach them how to adulterate this commodity. It is no easy thing to discover this cheat, when the sand has been well blended with the ladanum; in order to which you must chew it for some time, to find whether it crackles between the teeth, and if it doth, you must first dissolve it, and then strain it, in order to purify away what has been added to it.

CITHAREXYLUM. Lin. Gen. Plant. 678. Fiddle-wood.

The CHARACTERS are,

The empalement of the flower is bell-shaped, of one leaf, indented in five parts. The flower is of one leaf, funnel-shaped, divided at the top into five equal parts, which spread open. It hath four stamina which adhere to the tube, two of them being longer than the other, terminated by oblong summits with two lobes. In the center is situated the roundish germen, supporting a slender style, crowned by an obtuse double-headed stigma. The germen afterward becomes a capsule with two cells, each having a single seed.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia; the plants of this section have two long, and two short stamina, and the seeds are included in a capsule.

The SPECIES are,

1. **CITHAREXYLUM** (*Cinereum*) ramis angulatis, foliis ovato-lanceolatis venis candicantibus. *Fiddle-wood with angular branches, and oval spear-shaped leaves, having white veins. Citharexylum arbor laurifolia Americana, foliorum venis latis candicantibus. Pluk. Almag. 108. Fiddle-wood with oval spear-shaped leaves, which are veined, indented, and placed by threes, angular branches, and flowers growing in loose bunches. This is the common Fiddle-wood of America.*
2. **CITHAREXYLUM** (*Album*) foliis oblongo-ovatis, integris, oppositis, ramis angulatis, floribus spicatis. *Fiddle-wood with oblong, oval, entire leaves growing opposite, angular branches, and flowers growing in spikes. Berberis fructu arbor maxima baccifera, racemosa, foliis integris obtusis, flore albo pentapetalo odoratissimo, fructu nigro monopyreno. Sloan. Cat. Jam. 170. Fiddle-wood, or Fiddle-wood.*

The first sort grows common in most of the islands in the West-Indies, where it rises to a great height, and becomes a very large timber-tree; the wood of which is greatly esteemed for buildings, being very durable.

This hath an upright trunk fifty or sixty feet high, sending out branches on every side, which have several angles, or ribs, running longitudinally, garnished by three oval spear-shaped leaves at every joint, standing in a triangle, upon short foot-stalks. The leaves are about four inches long, and one or two broad, of a lively green colour, pretty much notched on their edges, having several deep veins running from the midrib to the edges, which are of a white colour on their upper side, and very prominent on their under. The flowers come out from the sides, and also at the end of the branches, in loose bunches, which are succeeded by small pulpy berries, inclosing two seeds in each.

The second sort is a native of the same islands with

the first. This is also a very large tree, whose timber is greatly valued in America, for buildings, being very durable; and from thence I have been informed the French gave it the title of Fidelle-wood, which the English have rendered Fiddle-wood; and some have supposed that the wood was used for making those musical instruments, which is a great mistake.

This tree rises with a strong upright trunk to the height of sixty feet or more, sending out many angular branches, standing opposite, which are covered with a loose whitish bark, (from whence the inhabitants give it the name of white Fiddle-wood,) garnished with oval oblong leaves, standing opposite, on short foot-stalks; these are of a lucid green, and are rounded at their ends. The flowers come out in long loose spikes, toward the end of the branches, which are white, and smell very sweet; these are followed by small, roundish, pulpy berries, each inclosing a single seed.

The first sort hath been long preserved in some of the curious gardens in England, for the sake of variety. The leaves continuing through the year, and being of a fine green colour, make a pretty variety in the stove during the winter season: this may be propagated either by seeds, or cuttings; the latter is the usual method in England, where the seeds are not produced; but when seeds can be obtained from abroad, the plants which rise from them are much better than those raised from cuttings.

The seeds of this sort should be sown in small pots early in the spring, and plunged into a fresh hot-bed of tanners bark, and treated in the same manner as other exotic seeds, which are brought from hot countries. If the seeds are fresh, the plants will appear in six or seven weeks, and in about one month more will be fit to transplant; when this is done, the plants should be carefully separated, so as not to tear, or break off their roots, and each planted in a small pot filled with light fresh earth, and plunged into the hot-bed again, observing to shade them till they have taken fresh root; after which they should have a large share of air admitted to them in warm weather, and must be frequently watered; in autumn the plants should be removed into the bark-stove, where it will be proper to keep them the first winter, till they have obtained strength; then they may be afterward kept in a dry stove in winter, and in the middle of summer they may be exposed in the open air for two or three months, in a warm situation, with which management the plants will make better progress than when they are more tenderly treated.

If the cuttings of these plants are planted in small pots during the summer months, and plunged into a moderate hot-bed, they will take root, and may afterward be treated in the same manner as the seedling plants.

The seeds of the second sort were sent me by William Williams, Esq; from Jamaica, which have succeeded in the physic garden at Chelsea; but as the plants have not yet flowered, I can give no other account of them, than what is before-mentioned; however, they seem to be full as hardy as those of the first sort, and make full as great progress. The leaves of this sort continue all the year, and having a glossy green colour, make a pretty appearance in the winter season.

CITRUS. Lin. Gen. Plant. 807. Citreum. Tourn. Inf. R. H. 620. tab. 395, 396. The Citron-tree.

The CHARACTERS are,

The empalement of the flower is of one leaf, indented in five parts. The flower hath five oblong, thick petals, which spread open, and are a little concave; it hath ten stamina, which are not equal, and join in three bodies at their base, terminated by oblong summits. The oval germen in the center supports a cylindrical style, crowned by a globular stigma; the germen afterward becomes an oblong fruit, with a thick fleshy skin filled with a succulent pulp, having many cells, each containing two oval hard seeds.

Dr. Linnæus has joined the Aurantium and Limon to this genus, making them only different species of the same genus; but all the varieties of Citron which

I have

I have examined, have but ten stamina in their flowers, whereas those of the Orange have more, so that these may be separated on that difference; but Tournefort adds, as a distinguishing character to this genus, the appendix which grows to the foot-stalk of the leaf. However, I shall not so closely follow Linnaeus, in joining those things together, which have by all the writers on botany and gardening been kept separate, lest I should render this work unintelligible to those who have not made botany their study.

The SPECIES are,

1. CITRUS (*Medica*) fructu oblongo, majori, mucronato, cortice crasso rugoso. Citron with a larger, oblong, pointed fruit, having a thick rough rind. Malum Citreum dulci medulla. Fer. Help. 72. *The Sweet Citron.*
2. CITRUS (*Tuberosa*) fructu oblongo, cortice tuberosa rugoso. Citron with an oblong fruit, having a rough knotted rind. Malum Citreum vulgare. Fer. Help. 57. *The common Citron.*

There are several varieties of this fruit, with which the English gardens have been supplied from Genoa, where is the great nursery for the several parts of Europe for this sort, as also Orange and Lemon-trees; and the gardeners who cultivate them there, are as fond of introducing a new variety to their collection, as the nursery-men in England are of a new Pear, Apple, Peach, &c. so that the varieties being annually increased, as are many of our fruits from seeds, there is like to be no end of the variety of these, nor of the Orange and Lemon-trees.

The fruit of the Citron is seldom eaten raw, as those of the Orange, but they are generally preserved, and made into sweetmeats, which are by some persons greatly esteemed; and as these are kept till winter and spring, when there is a scarcity of fruit for furnishing out the desert, they are the more valuable; but unless the seasons are warm, and the trees are well managed, the fruit rarely ripens in England. Some of the fairest fruit which I have seen growing in England, were in the gardens of his late grace the Duke of Argyle, at Whitton, where the trees were trained against a south wall, through which there are flues contrived for warming the air in winter, and glass-covers to put over them when the weather begins to be cold. In this place the fruit were as large, and perfectly ripe, as they are in Italy or Spain.

The several sorts of Citrons are cultivated much in the same manner as the Orange-tree, to which I shall refer the reader, to avoid repetition; but shall only remark, that these are somewhat tenderer than the Orange, and should therefore have a warmer situation in winter, otherwise they are very subject to cast their fruit. They should also continue a little longer in the house in the spring, and be carried in again sooner in the autumn; as also have a warmer and better defended situation in the summer, though not too much exposed to the sun in the heat of the day.

And as their leaves are larger, and their shoots stronger, than those of the Orange, they require a little more water in the summer; but in winter they should have but little water at each time, which must be the oftener repeated. The soil ought to be much the same as for the Orange-tree, but not quite so strong.

The common Citron is much the best stock to bud any of the Orange or Lemon kinds upon, it being the straightest and freest growing tree. The rind is smoother, and the wood less knotty, than either the Orange or Lemon; and will take either sort full as well as its own kind, which is what none of the other sorts will do: and these stocks, if rightly managed, will be very strong the second year after sowing, capable to receive any buds, and will have strength to force them out vigorously; whereas it often happens, when these buds are inoculated into weak stocks, they frequently die, or remain till the second year before they put out; and those that shoot the next spring after budding, are oftentimes so weak as hardly to be

fit to remain, being incapable to make a strait hand-some stem, which is the great beauty of these trees.

CITRUL. See PEPO.

CLARY. See SCLAREA.

CLAYTONIA. Gron. Flor. Virg. Lin. Gen. Plant. 253.

The CHARACTERS are,

The flower hath a two-leaved oval empalement, with a transverse base: it hath five oblong oval petals, which are indented at the top, and five awl-shaped recurved stamina, which are shorter than the petals, terminated by oblong summits. In the center is situated an oval germen, supporting a single style, crowned by a trifid stigma. The germen afterward becomes a roundish capsule, having three cells, opening with three elastic valves, and filled with round seeds.

This genus of plants is ranged in the first section of Linnaeus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and but one style.

The SPECIES are,

1. CLAYTONIA (*Virginica*) foliis linearibus. Lin. Sp. Plant. 294. *Claytonia with very narrow leaves.* Ornithogalo affinis Virginiana, flore purpureo pentapetaloides. Pluk. Alm. 272.
2. CLAYTONIA (*Siberica*) foliis ovatis. Lin. Sp. Plant. 294. *Claytonia with oval leaves.* Linnaea. Act. Stockh. 1746.

The first sort grows naturally in Virginia, from whence it was sent by Mr. Clayton to England, and received its title from him.

It hath a small tuberous root, which sends out low slender stalks in the spring, about three inches high, which have each two or three succulent narrow leaves about two inches long, of a deep green colour. At the top of the stalk are four or five flowers produced, standing in a loose bunch; these are composed of five white petals which spread open, and are spotted with red on their inside; after these fall away, the germen becomes a roundish capsule divided into three cells, which are filled with roundish seeds. The flowers appear in April, and the seeds ripen in June, soon after which the plant decays to the root.

The second sort grows naturally in Siberia. This is a low plant, seldom rising more than two or three inches high; the root is tuberous, sending out three or four oval leaves; the foot-stalk of the flower arises immediately from the root, sustaining two or three small white flowers of the same shape with those of the first sort, so make but little figure in a garden.

The plants are both propagated by seeds, and also from offsets sent out from the roots: the seeds should be sown upon a shady border of light earth, or in pots filled with the like mould, soon after they are ripe; for if they are kept out of the ground till spring, the plants will not come up till the next year; whereas those which are sown early in the autumn, will grow the following spring, so that a whole year is gained. When the plants come up, they will require no other care but to keep them clean from weeds; and in the autumn, if some old tanners bark is spread over the surface of the ground, it will secure the roots from being injured by frost; which, if it should prove very severe, might injure the young plants, but in mild winters they will not require protection.

The best time to transplant the roots is about Michaelmas, when they are inactive; but as they are small, if great care is not taken in opening the ground, the roots may be buried and lost; for they are of a dark colour, so are not easily distinguished from the ground.

CLAVICLE [Clavicus, Lat.] a clasper or tendril.

CLEMATIS. Lin. Gen. Plant. 616. Clematitis.

C. B. P. 300. [Κλημάτις, of Κλημία, a twig or clasper, &c. because it climbs up trees with claspers, like those of Vines. Hence it is called Virgultum ductile, Ranunculus obsequiosus; and also Antrogenomene, and Flammula, as though producing a carbuncle; for the leaves being bruised, and applied to the skin, burn it into carbuncles, as it is in the pestilence;

lence; and Flammula, because if one leaf be cropped in a hot day in the summer season, and bruised, and presently put to the nostrils, it will cause a smell and pain like a flame:] Virgin's Bower.

The CHARACTERS are,

The flowers have no empalment; they have each four loose oblong petals, with a great number of stamina, which are shorter than the petals, and the summits adhere to their side. They have many germen, which are roundish and compressed; the awl-shaped style, which is longer than the stamina, is crowned by a single stigma. The germina afterward become so many roundish compressed seeds, with the style sitting on their top, and are collected into a head, the styles of the several species being of various forms.

This genus of plants is ranged in the seventh section of Linnæus's thirteenth class, intitled Polyandria Polygynia, the flowers of this section having many stamina and several styles.

The SPECIES are,

1. CLEMATIS (*Reita*) foliis pinnatis, foliolis ovato-lanceolatis, integerrimis, caule erecto. Hort. Cliff. 225. *Clematis with winged leaves, whose lobes are oval, spear-shaped, entire, and an upright stalk. Clematidis five flammula surrecta alba.* J. B. 2. 127. *Upright white Climber.*
2. CLEMATIS (*Integrifolia*) foliis simplicibus, ovato-lanceolatis. Hort. Cliff. 225. *Clematis with single leaves, which are oval and spear-shaped. Clematidis cærulea erecta.* C. B. P. 300. *Upright blue Climber.*
3. CLEMATIS (*Hispanica*) foliis pinnatis, foliolis lanceolatis, acutis, integerrimis, caule erecto. *Clematis with winged leaves, whose lobes are spear-shaped, pointed, and entire, and an upright stalk. Clematidis Hispanica surrecta altera & humilior flore albicante.* H. R. Par.
4. CLEMATIS (*Vitalba*) foliis pinnatis, foliolis cordatis, scandentibus. Hort. Cliff. 225. *Clematis with winged leaves, whose lobes are heart-shaped and climbing. Clematidis latifolia integra.* J. B. 2. p. 125. *Climber with broad entire leaves, commonly called Viorna, or Traveller's Joy.*
5. CLEMATIS (*Canadensis*) foliis ternatis, foliolis cordatis, acutis, dentatis, scandentibus. *Clematis with trifoliate, heart-shaped, pointed leaves, which are indented, and climbing. Clematidis Canadensis latifolia & triphylla.* Sar. *Broad-leaved Canada Climber.*
6. CLEMATIS (*Flammula*) foliis inferioribus, pinnatis, laciniatis, summis simplicibus, integerrimis, lanceolatis. Hort. Cliff. 225. *Clematis whose lower leaves are winged and jagged, and the upper ones single, spear-shaped, and entire. Clematidis five flammula repens.* C. B. P. 300. *Creeping Climber.*
7. CLEMATIS (*Cirrhosa*) cirrhis scandens foliis simplicibus. Hort. Cliff. 226. *Clematis with climbing tendrils, and simple leaves. Clematidis peregrina, foliis pyri incisis.* C. B. P. 300. *Foreign Climber with cut Pear-shaped leaves.*
8. CLEMATIS (*Viticella*) foliis compositis decompositisque, foliolis ovatis, integerrimis. Hort. Cliff. 225. *Clematis with compound and decomposed leaves, whose small leaves are oval and entire. Clematidis cærulea vel purpurea repens.* C. B. P. 300. *Single blue Virgin's Bower.*
9. CLEMATIS (*Alpina*) foliis compositis ternatis ternatisque, foliolis acutis ferratis. *Clematis with compound leaves, whose lobes are sharply sawed. Clematidis Alpina geranii folio.* C. B. P. 300. *Alpine Climber with a Crane's-bill leaf.*
10. CLEMATIS (*Viorna*) foliis compositis decompositisque, foliolis quibusdam trifidis. Flor. Virg. 62. *Clematis with compound and decomposed leaves, some of whose lobes are trifid. Clematis purpurea repens, petalis florum coriaceis.* Raii Hist. 1928. *Creeping purple Climber, with coriaceous petals to the flower.*
11. CLEMATIS (*Orientalis*) foliis compositis, foliolis incisis angulatis lobatis cuneiformibus, petalis interne villosis. Lin. Sp. 765. *Clematis with compound leaves, whose small leaves are cut into angular wedge-shaped lobes, and the inside of the petals are hairy. Clematidis Orientalis folio apii, flore ex viridi flavescente, poste-*

rius reflexo. Tourn. Cor. 20. *Eastern Climber with a Smallage leaf, and a reflexed, greenish; yellow flower.*

12. CLEMATIS (*Sibirica*) foliis compositis & decompositis, foliolis ternatis, ferratis. Gmel. *Climber with compound and decomposed leaves, whose small leaves are sawed and trifoliate.*
13. CLEMATIS (*Dioica*) foliis ternatis, integerrimis, floribus diocis. *Three-leaved Climber, with entire leaves, having three lobes, and male and female flowers on the same plant. Clematis foliis ternis.* Sloan. Cat. 84. *Three-leaved Climber.*
14. CLEMATIS (*Americana*) foliis ternatis, foliolis cordato-acuminatis, integerrimis, floribus corymbosis. *Three-leaved Climber with heart-shaped pointed lobes, which are entire, and flowers collected in round bunches. Clematidis Americana triphylla, foliis non dentatis.* Houst. MSS.
15. CLEMATIS (*Crispa*) foliis simplicibus, ternatisque, foliolis integris trilobisque. Lin. Sp. Plant. 543. *Climber with single and trifoliate leaves, whose small leaves are either entire, or have three lobes. Clematis flore crispo.* Hort. Elth. 86. *Climber with a curled flower.*

The first sort grows naturally in the south of France, Italy, Austria, and several parts of Germany, but hath been long cultivated in the English gardens for ornament. This hath a perennial root. The stalks are upright, about three or four feet high, garnished with winged leaves standing opposite, which are composed of three or four pair of lobes, terminated by an odd one; they are oval, spear-shaped, and entire: the flowers are produced in large loose panicles at the top of the stalks; these are composed of four white petals, which spread open; and the middle is occupied by a great number of stamina, surrounding five or six germen, which afterward become so many compressed seeds, each having a long tail or beard sitting on the top. It flowers in June, and the seeds ripen in September.

The second sort grows naturally in Hungary and Tartary, but hath been long an inhabitant in the English gardens. The root of this is perennial, sending up many slender upright stalks, from three to four feet high, garnished with opposite single leaves at each joint, having short foot-stalks; the leaves are near four inches long, and an inch and an half broad in the middle, of a bright green, smooth, and entire, ending in a point: the flowers come out from the upper part of the stalks, standing upon very long naked foot-stalks, each supporting a single blue flower, composed of four narrow thick petals which spread open, and many hairy stamina surrounding the germina in the center. After the flowers are past, the germen become so many compressed seeds, each having a tail or beard. It flowers and seeds at the same time with the former sort.

The third sort is very like the first, from which it differs in having but two or three pair of lobes in each leaf, which are narrower and stand farther asunder: the stalks are shorter, and the flowers larger.

The fourth sort grows naturally in the hedges, in most parts of England. This hath a tough climbing stalk, sending out clasps, by which it fastens to the neighbouring bushes and trees, and sometimes rises more than twenty feet high, sending out many side branches, so as often to cover all the trees and bushes of the hedge. This puts out many bunches of white flowers in June, which are succeeded by several flat seeds joined in a head, each having a long twisted tail sitting on the top, which is covered with long white hairs; and in autumn, when the seeds are near ripe, they appear like beards, from whence the country people call it Old Man's Beard. The branches of this being very tough and flexible, are used for tying up faggots; from whence, in some countries, it is called Bindwith.

There are two varieties of this, one with indented leaves, which is the most common, and the other hath entire leaves; but as these are supposed to arise accidentally from seeds, they are not distinguished by later botanists.

The fifth sort grows naturally in most parts of North America, from whence the seeds have been brought to Europe. This is in its first appearance very like the last sort, but the leaves are broader, and grow by threes on the same foot-stalk; whereas those of the former have five or seven lobes in each leaf. The flowers appear at the same time with the former, but the seeds do not ripen in England, unless the season is very warm. There is little beauty in this sort.

The sixth sort hath a climbing stalk like the fourth; the lower leaves of this are winged, and deeply cut on their edges, but the upper leaves are single, spear-shaped, and entire. The flowers of this sort are white, and appear in June or July. This grows naturally in the south of France, and in Italy.

The seventh sort grows naturally in Spain and Portugal. This hath a climbing stalk, which will rise to the height of eight or ten feet, sending out branches from every joint, whereby it becomes a very thick bushy plant; the leaves are sometimes single, at other times double, and frequently trifoliate, being indented on their edges. These keep their verdure all the year: opposite to the leaves come out clasps, which fasten themselves to the neighbouring shrubs, by which the branches are supported; otherwise they would fall to the ground. The flowers are produced from the side of the branches; these are large, of an herbaceous colour, and appear always about the end of December, or beginning of January, which being a season when few persons visit gardens for information, these flowers have escaped their notice, so that many have supposed this sort doth not produce flowers in England; and the flowers being nearly the same colour of the leaves, those who have been more constant visitors of gardens, have passed by this plant, without noticing the flowers; but for many years together, it hath produced plenty of flowers in the garden at Chelsea, and always at the same season.

The seventh sort is cultivated in the nursery-gardens for sale, and is known by the title of Virgin's Bower. There are four varieties of it which are preserved in the gardens of the curious, and have been by some treated as so many distinct species; but as their only differences consist either in the colour of their flowers, or the multiplicity of their petals, they are now only esteemed as seminal variations; but as they are distinguished by the nursery-gardeners, I shall just mention them.

1. Single blue Virgin's Bower.
2. Single purple Virgin's Bower.
3. Single red Virgin's Bower.
4. Double purple Virgin's Bower.

These have no difference in their stalks or leaves, so that the same description will fit them all, excepting the colours or multiplicity of petals in their flowers.

The stalks of these plants are very slender and weak, having many joints, from whence come out side branches, which are again divided into smaller. If these are supported, they will rise to the height of eight or ten feet, and are garnished with compound winged leaves, placed opposite at the joints. These branch out into many divisions, each of which hath a slender foot-stalk, with three small leaves, which are oval and entire: from the same joint, generally four foot-stalks arise, two on each side; the two lower have three of these divisions, so that they are each composed of nine small leaves or lobes; but the two upper have only two opposite leaves on each, and between these arise three slender foot-stalks, each supporting one flower. The flowers have each four petals, which are narrow at their base, but are broad at the top and rounded: in one they are of a dark worn-out purple, in another blue, and the third of a bright purple or red colour. The double sort, which is common in the English gardens, is of the worn-out purple colour: but the foreign catalogues mention double flowers of both the other colours, which may probably be found in some of their gardens; but as I have not seen them myself, I have not noticed

them. The double flowers have no stamina or germen, but in lieu of them, there is a multiplicity of petals, which are narrow, and turn inward at the top.

These plants grow naturally in the woods in Spain and Portugal, but have been long cultivated in the English gardens for ornament. They flower in June and July, but they seldom ripen seeds in England; and the double sort continues to the end of August.

The ninth sort grows naturally on the Alps; and other mountains in Italy. I received it from mount Baldus, where it grows in plenty. This hath a slender climbing stalk, which rises three or four feet high, supporting itself by fastening to the neighbouring plants or shrubs. The leaves of this are composed of nine lobes or small leaves, three standing upon each foot-stalk, so that it is what the former writers stile a nine-leaved plant. The flowers come out at the joints of the stalk; in the same manner as the common Travellers Joy, which are white, so make no great appearance. This sort flowers in May.

The tenth sort grows naturally in Virginia and Carolina, from both of these countries I have received the seeds. This hath many slender stalks, garnished with compound winged leaves at each joint; and are generally composed of nine leaves, standing by threes, like those of the eighth sort, but the small leaves or lobes of this are nearly of a heart-shape. The flowers of this stand upon short foot-stalks, which come out from the wings of the leaves, one on each side the stalk. The flowers are composed of four thick petals, which are purple on their outside, and blue within. They appear in July, and if the autumn proves warm, the seeds will ripen in September.

The eleventh sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the royal garden at Paris, where they succeeded and perfected seeds, so that most of the gardens in Europe have been furnished with the seeds from thence: this hath weak climbing stalks, which fasten themselves by their clasps, to any plants or shrubs which stand near them, and thereby rise to the height of seven or eight feet, garnished with compound winged leaves, consisting of nine small leaves (or lobes) which are angular and sharp-pointed. The flowers come out from the wings of the leaves, which are of a yellowish green; and the petals are reflexed backward; they come out in April and May, and in warm seasons the seeds will ripen very well, if the plants have a good situation.

The twelfth sort grows naturally in Siberia, from whence the seeds were sent to the imperial garden at Peterburgh, where they succeeded and produced seeds, part of which were sent me in the year 1753. These grew, and the plants have flowered several years in the Chelsea garden. It hath weak climbing stalks which require support, that rise from four to six or eight feet high; the joints are far asunder; at each of these come out two compound winged leaves, whose small leaves or lobes are placed by threes; these are deeply sawed on their edges, and terminate in sharp points. The flowers come out from the wings of the leaves single, standing upon long haked foot-stalks, and are composed of four broad obtuse petals, which spread open in form of a cross, of a whitish yellow colour. In the center is placed several germen, surrounded by a great number of stamina, with flat compressed summits, of the same colour with the petals of the flower; after these are past, the germen become so many compressed seeds, each having a bearded tail. It flowers in February March and April, and the seeds ripen in July or August.

The thirteenth sort was sent me from Jamaica by the late Dr. Houstoun. This hath slender climbing stalks, which fasten themselves to the trees and shrubs which stand near them, and thereby rise to the height of ten or twelve feet, garnished with trifoliate leaves, coming out on each side the stalk; the lobes are large, oval, and entire, having three longitudinal veins. The foot-stalks of the flowers arise at the

U u u same

same joints, close to those of the leaves, one on each side the stalks: these are long, naked, and grow horizontally, extending beyond the leaves before they divide and branch; then there comes out three or four pair of small foot-stalks from the large one, each of which divides again into three smaller, each supporting a single flower: the lower pair of these are extended four or five inches, the other gradually diminish to the top, so that they form a pyramidal thyrse of flowers; these are white, and are composed of four narrow petals which are reflexed back, but the stamina all stand erect.

This hath been by some persons supposed to be the same with the common Travellers Joy, but those who have seen the two plants, cannot doubt of their being distinct species.

The fourteenth sort was sent me from Campeachy by the late Dr. Houstoun. This hath strong climbing stalks, which fasten themselves by their clasps to the neighbouring trees, whereby they are supported, and rise to the height of twenty feet or more, garnished at each joint by trifoliate leaves, which are heart-shaped, pointed, and entire. The flowers come out on long, naked, branching foot-stalks, which rise from the wings of the leaves; they are white, and collected into roundish bunches; these are succeeded by seeds shaped like those of the common sort, but have long curling beards to each, which are finely feathered.

The fifteenth sort grows naturally in Carolina, from whence I received the seeds in the year 1726. This hath weak stalks which rise near four feet high, and by their clasps fasten themselves to the neighbouring plants, whereby they are supported. The leaves come out opposite at the joints; these are sometimes single, at others trifoliate, and some of the leaves are divided into three lobes. The flowers come out singly from the side of the branches upon short foot-stalks, which have one or two pair of leaves below the flower, which are oblong and sharp-pointed. The flowers have four thick petals, like those of the tenth sort; these are of a purple colour, and their inner surface is curled, and hath many longitudinal furrows. This flowers in July, and the seeds ripen in September.

The three first sorts have perennial roots, which multiply pretty fast, but their stalks die down every autumn, and new ones arise in the spring, in which particular they differ from all the other species, therefore require different management, and are propagated in a different manner; therefore I shall first give directions for their culture.

These plants are propagated either by seeds, or parting their roots; but the former being a tedious method (the plants seldom rising until the second year after sowing, unless the seeds are sown in the autumn soon after they are ripe, and are often two years more before they flower,) the latter is generally practised. The best season for parting these roots is in October or February; either just before their branches decay, or before they rise again in the spring.

They will grow almost in any soil or situation; but if the soil is very dry, they should always be new planted in the autumn, otherwise their flowers will not be so strong; but if the soil be wet, it is better to defer it until the spring. The roots may be cut through their crowns with a sharp knife, observing to preserve to every offset some good buds or eyes; and then it matters not how small you divide them, for their roots increase very fast: but if you part them very small, you should let them remain three or four years before they are again removed, that their flowers may be strong, and their roots multiplied in eyes, which in less time cannot be obtained.

These plants are extreme hardy, enduring the cold of our severest winters in the open air, and are very proper ornaments for large gardens, either to be planted in large borders, or intermixed with other hardy flowers in quarters of flowering shrubs; where, by being placed promiscuously in little open places,

they fill up those small vacancies, and are agreeable enough. They begin to flower about the beginning of June, and often continue to produce fresh flowers until August, which renders them valuable, especially since they require very little care in their culture; for their roots may be suffered to remain several years undisturbed, where there is no want to part them, which will not in the least prejudice them.

The fourth sort is found wild in most parts of England, growing upon the sides of banks under hedges, and extends its trailing branches over the trees and shrubs that are near it. This plant in the autumn is generally covered with seeds, which are collected into little heads, each of which having, as it were, a rough plume fastened to it, hath occasioned the country people to give it the name of Old Man's Beard. It is titled by Lobel and Gerard, Viorna; and by Dodonæus, Vitis alba: in English it is most commonly called Travellers Joy. This sort is rarely cultivated in gardens, being too rambling, and having but little beauty.

The fifth and sixth sorts have no more beauty than the fourth, so are seldom preserved in gardens, unless for the sake of variety. They are both as hardy as the common sort, and may be propagated either by seeds or laying down their branches.

The seventh sort retains its leaves all the year, which renders it valuable. This was formerly preserved in green-houses in the winter, supposing it too tender to live in the open air in England; but now it is generally planted in the full ground, where the plants thrive much better than in pots, and produce plenty of flowers, which they never did when they were more tenderly treated; nor have I found that the plants have suffered from severe frosts; for those which have been growing in the open air at Chelsea, more than fifty years, have resisted the greatest cold without covering.

This sort doth not produce seeds in England, so it is propagated by layers, and also from cuttings. If they are propagated by layers, it must be done in the beginning of October, when the shoots of the same year only should be chosen for this purpose; for the older branches do not put out roots in less than two years, whereas the tender shoots will make good roots in one year: these must be pegged down into the ground, in the same manner as is usually practised for other layers, to prevent their rising. If the shoots have two inches of earth over them, it will be better than a greater depth; but then, a little old tanners bark should be spread over the surface of the ground, to keep out the frost; for as the plants generally begin flowering about Christmas, so at the same time they are putting out roots, which being but just formed, may be injured by severe frosts: these layers will have strong roots by the following autumn, when they may be taken from the old plant, and transplanted where they are designed to remain.

When they are propagated by cuttings, they should be planted in March, in pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, observing to shade them from the sun in the day-time, and gently water them two or three times a week; and in less than two months they will have taken root, when they should be gradually inured to the open air. The following summer they may be placed in any part of the garden till Michaelmas, and then they should be turned out of the pots and planted in the full ground, either where they are designed to remain, or into a nursery-bed, to grow a year longer to get strength, before they are placed out for good.

All the varieties of Virgin's Bower are propagated by laying down their branches; for although the single flowers sometimes produce seeds in England, yet as these seeds, when sown, generally remain a whole year in the ground before they vegetate, so the other being the more expeditious method of increasing these plants, is generally practised: but in order to succeed, these layers should be laid down at a different

season

season from the former sort; for when they are laid in the autumn, their shoots are become tough, so rarely put out roots under two years; and after lying so long in the ground, not one in three of them will have made good roots; so that many have supposed these plants were difficult to propagate, but since they have altered their season of doing it, they have found these layers have succeeded as well as those of other plants.

The best time for laying down the branches is in the beginning of July, soon after they have made their first shoots, for it is these young branches of the same year, which freely take root; but as these are very tender, there should be great care taken not to break them in the operation: therefore those branches from which these shoots were produced, should be brought down to the ground, and fastened to prevent their rising; then the young shoots should be laid into the earth, with their tops raised upright, three or four inches above ground; and after the layers are placed down, if the surface of the ground be covered with moss, rotten tanners-bark, or other decayed mulch, it will prevent the ground from drying, so that the layers will not require watering above three or four times, which should not be at less than five or six days interval; for when these layers have too much wet, the tender shoots frequently rot; or when the young fibres are newly put out, they are so tender, as to perish by having much wet: therefore where the method here directed is practised, the layers will more certainly take root, than by any other yet practised.

As most of these plants have climbing branches, they should be always planted where they may be supported, otherwise the branches will fall to the ground and appear unsightly; so that unless they are properly disposed, instead of being ornaments to a garden, they will become the reverse. Where there are arbours or seats, with trellis work round them, these plants are very proper to train up against it; or where any walls or other fences require to be covered from the sight, these plants are very proper for the purpose; but they are by no means proper for open borders, nor do they answer the expectation, when they are intermixed with shrubs; for unless their branches have room to extend, they will not be productive of many flowers.

The sort with double flowers is the most beautiful, so that should be preferred to those with single flowers, of which a few only should be planted for variety. They are all equally hardy, so are seldom injured by frost, excepting in very severe winters, when sometimes the very tender shoots are killed; but if these are cut off in the spring, the stems will put out new shoots.

The tenth, eleventh, and fifteenth sorts are also very hardy plants, and have climbing branches, so may be disposed in the same manner as the other: they are also propagated by layers, which will succeed, if performed at the same time, and in the same manner as is directed for them.

The other sorts are natives of the warmest parts of America, so will not thrive in this country, unless they are preserved in stoves; but as these are great ramblers and plants of no great beauty, they are seldom preserved in Europe, but in botanic gardens for the sake of variety. These may be propagated by layers, in the same manner as the other sorts; or may be raised from seeds, obtained from the countries where they naturally grow; but these must be treated in the same manner as other exotic plants from the same country.

CLEOME. Lin. Gen. Plant. 740. Sinapisrum. Tourn. Inst. R. H. 231. tab. 116.

The CHARACTERS are,

The flower hath a four-leaved empalement which spreads open: it hath four petals which are inclined upward and spread open, the two lower being less than the other; in the bottom there are three mellow glands which are roundish, and are separated by the empalement. It hath six or more

stamina which are incurved, having rising summits fixed to their side: it hath a single style, supporting an oblong germen, which is of the same length as the stamina, and crowned by a thick stigma. The germen afterward becomes a long cylindrical pod, sitting upon the style, having one cell, opening with two valves, and filled with roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradynamia Siliquosa; the plants of this section have in the flowers four long and two short stamina, and their seeds are included in long pods.

The SPECIES are,

1. CLEOME (*Pentaphylla*) floribus gynandris, foliis quinatis caule inermi. Lin. Sp. 938. *Cleome with flowers having male and female parts, five leaves, and smooth stalks.* Sinapisrum Indicum, pentaphyllum flore carneo, minus, non spinosum. H. L.
2. CLEOME (*Ornithopodoides*) floribus hexandris, foliis ternatis, foliolis ovato-lanceolatis. Lin. Sp. Plant. 940. *Cleome with flowers having six stamina, trifoliate leaves, and spear-shaped lobes.* Sinapisrum Orientale, triphyllum, ornithopodii filiquis. Tourn. Cor. 17.
3. CLEOME (*Lusitanica*) floribus hexandris, foliis ternatis, foliolis linearilanceolatis, filiquis bivalvibus. *Cleome with flowers having six stamina, trifoliate leaves, narrow spear-shaped lobes, and pods having two valves.* Sinapisrum Lusitanicum triphyllum, flore rubro. Tourn. Inst. R. H. 231.
4. CLEOME (*Viscosa*) floribus dodecandris, foliis quinatis ternatisque. Flor. Zeyl. 241. *Cleome with flowers having twelve stamina, trifoliate and quinquefoliate leaves.* Sinapisrum Zeylanicum, triphyllon & pentaphyllum viscosum, flavo flore. Mart. Dec. 3.
5. CLEOME (*Triphylla*) floribus hexandris, foliis ternatis, foliolo intermedio majori. *Cleome with flowers having six stamina, and trifoliate leaves, whose middle lobe is the largest.* Sinapisrum Indicum triphyllum, flore carneo non spinosum. H. L.
6. CLEOME (*Erucago*) floribus hexandris, foliis septenis, caule spinoso, filiquis pendulis. *Cleome with flowers having six stamina, leaves with seven lobes, a prickly stalk, and hanging pods.* Sinapisrum Ægyptiacum heptaphyllum, flore carneo, majus spinosum. H. L.
7. CLEOME (*Spinosa*) floribus hexandris, foliis quinatis ternatisque, caule spinoso. *Cleome with flowers having six stamina, leaves composed of five and three lobes, and a prickly stalk.* Sinapisrum Indicum spinosum, flore carneo, folio trifido vel quinquefido. Houst. MSS.
8. CLEOME (*Monophylla*) floribus hexandris, foliis simplicibus, petiolatis ovato-lanceolatis. Flor. Zeyl. 243. *Cleome with six stamina to the flowers, and six leaves, which are ovally spear-shaped.* Sinapisrum Zeylanicum viscosum, folio solitario, flore flavo, filiquâ tenui. Burm. Thes. 217.

The first sort grows naturally in Asia, Africa, and America; I have received the seeds of it from Aleppo, and the coast of Guinea, and in the earth which came from the West-Indies with other plants; this hath come up as a weed. It rises with an herbaceous stalk about a foot high, garnished with smooth leaves, composed of five small leaves or lobes, joining at their base to one center, and spread out like the fingers of a hand. The leaves on the lower part of the stalk stand upon long foot-stalks, which are gradually shortened to the top of the stalk, where they almost join it: the flowers are produced in loose spikes at the end of the stalks and branches; these have four petals of a flesh colour, which stand erect, spreading from each other; and below these are placed the stamina and style, which coalesce at the bottom, and are stretched out beyond the petals, where they spread open; after the flower is past, the germen which sits upon the style, becomes a taper pod, about two inches long, filled with round seeds. This is an annual plant, which dies soon after the seeds are ripe.

The second sort grows naturally in the Levant, from whence Dr. Tournefort sent the seeds to the royal garden at Paris, and from thence most of the botanic gardens in Europe have been furnished with it: this rises

rises with an upright stalk about the same height as the first, garnished with leaves composed of three spear-shaped lobes, standing upon short foot-stalks; the flowers come out singly from the side of the stalks, and have four red petals, which stand in the same form as those of the former sort: these are succeeded by slender pods two inches long, which swell in every division, where each seed is lodged, so as to appear like joints, as those do of the Bird's-foot Trefoil; when the seeds are ripe, the whole plant decays. If the seeds of this are sown in autumn the plants will flower in June, and their seeds will ripen in August, but those which are sown in the spring do not flower till July; so that unless the season proves favourable, the seeds will not ripen: if the seeds of this sort are permitted to scatter, the plants will come up without care, and require only to be thinned and kept clean from weeds, for they will not bear transplanting.

The third sort grows naturally in Portugal and Spain, from whence I have received the seeds. This rises with an herbaceous stalk about a foot and half high, sending out a few short side branches, which are garnished with leaves composed of three narrow lobes, standing upon short foot-stalks. The flowers come out singly from the side of the stalks, are of a deep red colour, and are succeeded by thick taper pods, filled with round seeds. This is an annual plant, which will thrive in the open air, and requires the same treatment as the former.

The fourth sort grows naturally in the island of Ceylon, from whence the seeds were brought to Holland, where they succeeded, and the seeds were sent me by the late Dr. Boerhaave; this rises near two feet high, sending out several side branches, garnished with leaves, some of which have five, and others three roundish lobes standing upon short hairy foot-stalks. The flowers come out singly at the foot-stalks of the leaves, they are of a pale yellow, and are succeeded by taper pods between two and three inches long, ending in a point, which are full of round seeds. The whole plant sweats out a viscous clammy juice. This is also an annual plant.

The fifth sort was sent me from Jamaica by the late Dr. Houstoun, in the year 1730. This is an annual plant which rises two feet high, sending out many side branches, garnished with leaves, with one large spear-shaped lobe in the middle, and two very small ones on the side; these sit close to the branches. The flowers come out singly from the side of the branches, upon long foot-stalks: these have four large flesh-coloured petals, and six long stamina, which stand out beyond the petals; when the flowers fade, the germen which sits upon the style becomes a taper pod four inches long, filled with round seeds.

The sixth sort was sent me from Jamaica by the late Dr. Houstoun, who found it growing naturally there in great plenty. It also grows naturally in Egypt. This rises with a strong thick herbaceous stalk two feet and a half high, dividing into many branches, which are garnished with leaves composed of seven long spear-shaped lobes, joining in a center at their base, where they sit upon a long slender foot-stalk: just below the foot-stalk comes out one or two short, thick, yellow spines, which are very sharp. The flowers come out singly from the side of the branches, forming a long loose spike at their extremities; this spike hath single broad leaves, which half surround the stalks at their base, from the bosom of which, come out the foot-stalks of the flowers, which are two inches long, each sustaining a large flesh-coloured flower, whose style and stamina are extended two inches beyond the petals. After the flower is past, the germen, which sits upon the style, becomes a thick taper pod five inches long, which hangs downward, and is filled with round seeds. This is also an annual plant, which perishes soon after the seeds are ripe.

The seventh sort was sent me from the Havannah in the year 1731, by the late Dr. Houstoun. This is

also an annual plant, which rises near two feet high, branching out on every side: the lower leaves are composed of five oblong lobes standing upon long foot-stalks, but those on the stalks and branches have but three lobes, and have short foot-stalks: the main stalk and also the branches, are terminated by loose spikes of purple flowers, each sitting upon a slender foot-stalk, at the base of which is placed a single oval leaf. The stalks are armed with slender stiff spines, which are situated just under the foot-stalks of the leaves; when the flowers fade, the germen becomes a taper pod, two inches long, filled with round seeds.

The eighth sort grows naturally in Ceylon; this is an annual plant, which rises with an herbaceous stalk a foot and half high, garnished with long, narrow, single leaves, standing alternately on the stalks; from the wings of the leaves come out the foot-stalks of the flower, each sustaining a single yellow flower, which is succeeded by a very slender taper pod.

All these plants except the second and third sorts, are natives of very warm countries, so will not thrive in England without artificial heat; therefore their seeds must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be planted in separate small pots, filled with fresh light earth, and plunged into a fresh hot-bed, observing to shade them until they have taken fresh root; after which they should have air admitted to them every day in proportion to the warmth of the season, and their waterings should be frequently repeated, but not given in too great plenty; when the plants have filled these small pots with their roots, they should be put into larger, and plunged again into a hot-bed to bring them forward; and in July, when they are too tall to remain longer in the hot-bed, they should be removed into an airy glass case, where they may be screened from cold and wet, but in warm weather may enjoy the free air. With this management the plants will flower soon after, and perfect their seeds in autumn. The second and third sorts may be sown in the open borders of the garden, where they are designed to remain, for they do not require any artificial warmth.

CLEONIA, Portugal Self-heal.

The CHARACTERS are,
It hath a bilabiated empalement of one leaf, which is tubulous and angular; the upper lip is broad, plain, and indented in three parts; the under is short and divided into two. The flower is of the grinning kind, with one petal; the upper lip is erect and divided into two parts, the lower is trifid, the middle segment having two lobes, the two lateral spread asunder; it hath four stamina, the two lower being the longest, whose outer top of their summits form a cross. It hath four germen, supporting a slender style with four stigma, having four equal bristles; the germen afterward become four seeds, inclosed in the hairy empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, intitled Didynamia Gymnospermia, the flower having two long and two short stamina, and are succeeded by naked seeds filling in the empalement.

This plant grows naturally in Spain and Portugal; it is annual, perishing soon after it has ripened its seeds. It was formerly ranged under the genus of Bugula, Tournefort afterward titled it Clinopodium, and father Barrelier placed it with the Prunella, to which genus it is nearly related.

It is propagated by seeds, which, when sown in the autumn the plants will come up the following spring: but the seeds which are sown in the spring, frequently lie in the ground till the following autumn, and sometimes till the next spring before they vegetate. When the plants come up and are fit to transplant, a few of them may be planted into a border where they may remain to produce their flowers and seeds, as they require but little culture; so a few plants may be allowed to have place in small gardens, where they will not take much room.

CLETHRA. Gron. Fl. Virg. 43. Lin. Gen. Plant. 489.

The CHARACTERS are;

The flower hath a permanent empalement of one leaf, which is cut into five parts; it hath five oblong petals, which are longer than the empalement; it hath ten stamina which are as long as the petals, and are terminated by oblong erect summits; in the center is situated a roundish germen supporting a permanent erect style, crowned by a trifid stigma. The germen afterward becomes a roundish capsule inclosed by the empalement, having three cells, which are full of angular seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flowers having ten stamina, and one style.

We know but one SPECIES of this genus at present, viz.

CLETHRA (*Alnifolia*) Gron. Virg. 47. *There is no English title to this plant, it is the Alnifolia Americana serrata, floribus pentapetalis albis in spicam dispositis. Pluk. Alm. 18. American Shrub with an Alder sawed leaf, and white five-leaved flowers, disposed in a spike.*

This shrub is a native of Virginia and Carolina, where it grows in moist places, and near the sides of rivulets, rising to the height of eight or ten feet, but in this country it rarely rises to half that height: the leaves are in shape like those of the Alder-tree, but are longer; these are placed alternately upon the branches: the flowers are produced at the extremity of the branches, in close spikes: they are composed of five leaves, are white, and have ten stamina in each, which are nearly of the same length with the petals, this plant flowers in July, and when the autumn proves favourable, there are often some spikes of flowers again in October.

This is hardy enough to bear the open air in England, and is one of the most beautiful shrubs at the season of its flowering; which is very little later than in its native country, being commonly in flower here by the beginning of July; and if the season is not very hot, there will be part of the spikes in beauty till the beginning of August; and as most of the branches are terminated with these spikes of flowers, so when the shrubs are strong, they make a fine appearance at that season.

This will thrive much better in moist land than in dry ground, and requires a sheltered situation, where it may be defended from strong winds, which frequently break off the branches, where they are too much exposed to its violence. It is propagated by layers, but they are generally two years before they get root, so that at present it is rare in England. The finest shrubs of this kind, which I have yet seen, are in the curious garden of his grace the late duke of Argyle, at Whitton near Hounslow, where they thrive as well as in their native country. They may also be propagated by suckers, which are sent out from their roots; if these are carefully taken off with fibres in the autumn, and planted into a nursery-bed, they will be strong enough in two years to transplant where they are to remain.

It may also be propagated by seeds, which must be procured from the countries where it grows naturally, for the seeds are not perfected in England. But as these seldom arrive here till spring, so when they are sown at that season, the plants will not come up till the following spring. Therefore the seeds should be sown in pots, and placed in a shady situation till autumn, then placed under a frame in winter; the plants will come up the next spring, and in autumn may be transplanted into a nursery-bed, to get strength before they are placed to remain for good.

CLIFFORTIA. Lin. Gen. Plant. 1004.

The name was given to this genus of plants by Dr. Linnæus, in honour of Mr. George Clifford of Amsterdam; a great collector of plants, and a patron of botanists, who has printed a folio book of the plants in his garden, with several copper-plates, exhibiting the figures of many of the most curious plants. We have no English name for it.

The CHARACTERS are;

It hath male and female flowers in different plants: the male flowers have a spreading empalement, composed of three small, oval, concave leaves. It hath no petals, but a great number of hairy upright stamina, which are the length of the empalement, terminated by compressed, oblong, twin summits. The female flowers have a permanent empalement, composed of three leaves which are equal, sitting upon the germen; these have no petals, but the oblong germen which is situated below the empalement, supports two long, slender, feathered styles, terminated by a single stigma; the germen afterward becomes an oblong taper capsule, with two cells crowned by the empalement, including one narrow taper seed.

This genus of plants is ranged in the tenth section of Linnæus's twenty-second class, intitled Dioecia Polyandria; the plants of this section and class have male and female flowers on different plants, and the male flowers have a great number of stamina.

The SPECIES are,

1. CLIFFORTIA (*Ilicifolia*) foliis subcordatis, dentatis. Lin. Sp. Plant. 1308. *Cliffortia with heart-shaped indented leaves.* Arbuscula Afr. folio acuto ilicis caulem amplexo rigido. Boerh. Ind. alt. 2.
2. CLIFFORTIA (*Trifoliata*) foliis ternatis, intermedio tridentato. Prod. Leyd. 253. *Three-leaved Cliffortia, whose middle leaf is cut in three parts.* Myrica foliis ternatis; intermediis cuneiformibus tridentatis. Hort. Cliff. 456.
3. CLIFFORTIA (*Ruscifolia*) foliis lanceolatis, integerrimis. Hort. Cliff. 463. *Cliffortia with spear-shaped leaves which are entire.* Frutex Æthiopicus conifer, fructu parvo, sparsim intra folia rusci, seminibus cylindraceis.

The first sort grows naturally at the Cape of Good Hope, but hath been long cultivated in many of the English gardens; however it was not reduced to any genus, till Dr. Linnæus established this, and gave it the title. By some former writers it was called *Camphorata*, to which genus it had no relation.

It rises with a weak shrubby stalk four or five feet high, sending out many diffused branches, which spread out on every side, requiring some support: these are garnished with leaves, which are heart-shaped at their base, but broad at their ends, where they are sharply indented. They are very stiff, of a grayish colour, and closely embrace the stalks with their base, and are placed alternate on the branches; from the bosom of these arise a single flower, sitting close to the branch, having no foot-stalk. Before the empalement is spread open, it forms a bud, in shape and size of those of the Caper; this empalement is composed of three green leaves, which afterwards spread open, and then the numerous stamina appear standing erect; these, as also the inner surface of the empalement, are of a yellowish green colour. The flowers appear in June, July, and August, but the leaves continue in verdure through the year.

All the plants which I have seen of this sort, either in the English or Dutch gardens, were male, nor have I heard of any female plants being in any of the European gardens.

This plant is easily propagated by cuttings, which may be planted in any of the summer months; if these are planted in small pots filled with light earth, and plunged into a very moderate hot-bed they will soon take root, provided they are screened from the sun and duly watered; when they have taken root, they must be gradually inured to bear the open air, to which they should be exposed, to prevent their drawing up weak: therefore they should be placed abroad till they have obtained some strength, then they may be each transplanted into a separate small pot, and placed in the shade until they have taken fresh root; after which they may be placed with other of the hardy kinds of exotic plants in a sheltered situation till October, when they should be removed into the greenhouse, or placed under a common hot-bed frame, where they may be screened from the hard frost, but

X x x enjoy

enjoy the free air at all times when the weather is mild.

When the plants advance in height; their stems and branches must be supported, otherwise they will trail upon the ground. In summer they must be placed in the open air, with Myrtles and other hardy green-house plants; and in winter the plants may be treated in the same manner as those, but must have little water in winter. This plant has endured the cold of our ordinary winters, when planted near a south-west wall without covering, but in severe winters they are always destroyed.

The second sort is a native of the same country as the first; this hath very slender ligneous stalks, which must be supported, otherwise they will fall to the ground. These send out slender branches on every side, which are closely garnished with trifoliate leaves standing close to the branches; the middle lobes of these are much larger than the two side, and are indented in three parts. The flowers of this come out from the bosom of the leaves, having very short foot-stalks, and are shaped like those of the first, but are smaller; these appear in July and August. Of this sort we have only male plants in the English gardens, which can only be propagated by layers; and as these are two years before they take root, the plants are at present very rare in England. This sort requires the same management as the first, and is equally hardy, but must not be over watered in winter. The leaves of this sort continue green all the year, and being singularly shaped, they make a variety in the green-house during the winter season.

The third sort rises with a weak shrubby stalk about four feet high, sending out lateral branches, which are covered with a whitish bark, and are garnished with leaves, placed in clusters without order; these are stiff, of the consistence and colour of the Butchers Broom, but are narrower, and run out to a longer point. Between these clusters of leaves the flowers come out in loose bunches, these have a great number of yellowish stamina, included in a three-leaved empalement. We have only the male plant of this sort, which is very difficult to propagate, so is very rare in Europe at present.

This plant is tenderer than either of the former sorts, so should be placed in a warm green-house in winter, and during that season, they must have but little water. In the summer they may be exposed to the open air in a sheltered situation, but they should not remain abroad too late in the autumn; for if there should be much rain at that season, it would endanger these plants if they are exposed to it.

CLIMATE [of Κλίμα, Gr. an inclination,] is a part of the surface of the earth bounded by two circles parallel to the equator; so that the longest day in that parallel, nearest to the pole, exceeds the longest day in that parallel nearest to the equator by some certain space of time, viz. half an hour, till you come to places situate nearly under the arctic circle; and a whole hour, or even several days when you go beyond it.

The antient Greek geographers reckoned only seven climates from the equator towards the north pole, and denominated them from some noted place, through which the middle parallel of the climate passed; but the moderns reckon up twenty-four.

The beginning of the climate is the parallel circle, wherein the day is the shortest.

The end of the climate is that wherein the day is the longest.

The climates therefore are reckoned from the equator to the pole; and are so many bands or zones, terminated by lines parallel to the equator; though in strictness there are several climates in the breadth of one zone.

Each climate only differs from its contiguous ones, in that the longest day in summer is longer or shorter by half an hour in one place than the other.

As the climates commence from the equator, the first climate at its beginning has its longest day pre-

cisely twelve hours long; at its end twelve hours and a half; the second, which begins where the first ends, viz. at twelve hours and a half, ends at thirteen hours: and so of the rest, as far as the polar circles.

Here what geographers call hour-climates terminate, and month-climates commence.

As an hour-climate is a space comprised between two parallels of the equator, in the first of which the longest day exceeds that in the latter by half an hour; so the month-climate is a space between two circles parallel to the polar circles, whose longest day is longer or shorter than that of its contiguous one by a month, or thirty days.

The antients, who confined the climates to what they imagined the habitable part of the earth, only allowed of seven, as had been said: the first they made to pass through Meroe, the second through Sienna, the third through Alexandria, the fourth through Rhodes, the fifth through Rome, the sixth through Pontus, and the seventh through the mouth of the Borysthenes.

The moderns, who have sailed farther towards the poles, make thirty climates on each side; and because the obliquity of the sphere makes a little difference in the length of the longest day, some of them make the difference of the climate but a quarter of an hour instead of half an hour.

The term climate is vulgarly bestowed on any country or region differing from another, either in respect of the seasons, the quality of the soil, or even the manners of the inhabitants, without any regard to the length of the longest day.

CLINOPodium. Lin. Gen. Plant. 644. Tourn. Inst. R. H. 194. tab. 92. Field Basil.

The CHARACTERS are,

It hath an involucre cut into many parts, is the length of the empalement, upon which the whorls sit. The empalement is of one leaf, with a cylindrical tube, which is divided into two lips; the upper lip is broad, trifid, acute, and reflexed; the under lip is cut into two narrow segments, which turn inward. The flower is of the lip kind, with a short tube enlarging to the mouth; the upper lip is erect, concave, and indented at the top, which is obtuse; the under lip is trifid and obtuse, the middle segment being broad and indented. It hath four stamina under the upper lip, two of which are shorter than the other, terminated by roundish summits; in the center is situated the quadripartite germen, supporting a slender style the length of the stamina, crowned by a single compressed stigma. The germen afterward become four oval seeds shut up in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, intitled Didynamia Gymnospermia. The flowers of this class and section, have two long, and two short stamina, which are succeeded by four naked seeds.

The SPECIES are,

1. **CLINOPodium** (*Vulgare*) capitulis subrotundis, hispidis, bracteis setaceis. Lin. Sp. Plant. 587. Field Basil with roundish prickly heads, and bristly bractea. Clinopodium Origano simile, elatius, majore flore. C. B. P. 225. Common English Field Basil.
2. **CLINOPodium** (*Incanum*) foliis subtus tomentosis, verticillis explanatis, bracteis lanceolatis. Lin. Sp. Plant. 588. Field Basil with leaves which are woolly on the under side, broad plain whorls, and spear-shaped bractea. Clinopodium menthæ folio incanum, & odoratum. Hort. Elth. 87.
3. **CLINOPodium** (*Rugosum*) foliis rugosis, capitulis axillaribus, pedunculatis, explanatis, radiatis. Lin. Sp. Plant. 588. Field Basil with rough leaves, plain heads growing on the sides of the stalks, which have foot-stalks, and are radiated. Clinopodium rugosum, capitulis scabiosæ. Hort. Elth. 88.
4. **CLINOPodium** (*Humile*) humile ramosum, foliis rugosioribus, capitulis explanatis. Low branching Field Basil with rougher leaves, and plain heads. Clinopodium Americanum humile, foliis rugosioribus. Dale.

5. *CLINOPodium (Carolinianum)* caule erecto, non ramoso, foliis subtus villosis, verticillis paucioribus, bracteis calyce longioribus. *Field Basil with an upright unbranching stalk, leaves hairy on their under side, fewer whorls, and bractea longer than the empalement.* *Clinopodium Americanum*, erectum; non ramosum foliis longioribus, internodiis longissimis: Dale.

6. *CLINOPodium (Egyptiacum)* foliis ovatis rugosis, verticillis omnibus distantibus, i. e. *Field Basil with oval rough leaves, and the whorls of flowers standing at a great distance.* *Clinopodium Egyptiacum*, vulgari simile. Dill: *Egyptian Field Basil like the common.*

The first sort grows naturally by the side of hedges and in thickets, in many parts of England; this hath a perennial fibrous root, which sends up several stiff square stalks about a half high, from which come out a few lateral branches toward the top, garnished with oval hairy leaves, placed opposite; at the top of the stalks the flowers come out in round whorls, or heads; one of these terminate the stalk, and there is generally another which surrounds the stalk at the joint immediately below it. The flowers are sometimes purple, at others white, for they vary from one colour to the other, when they are propagated by seeds, so that both colours are found naturally in the fields. The whorls (or heads) grow very close, and each foot-stalk sustains several flowers; each flower hath a tubular empalement, ending in five sharp points, which stand erect; at the base of the empalement stand two bristly spines, which Linnæus terms the bractea; these stand almost horizontal under the empalement. The flower is of the labiated, or lip kind, according to Tournefort, Ray, &c. which is now styled ringent, or grinning, from the appearance which the upper part has to the mouth, or chaps of animals. The upper lip is broad and trifid, but the under is cut into two narrow segments; each flower is succeeded by four naked seeds, sitting at the bottom of the empalement. This flowers in June.

The second sort grows naturally in Pennsylvania and Carolina, from both of these countries I have frequently received the seeds; this hath a perennial root, which sends up many square stalks about two feet high, which put out a few short side branches toward the upper part, garnished with oblong oval leaves, about the size of those of Water Mint, standing opposite, close to the stalk; they are hoary, and soft to the touch, and have a strong odour, between that of Marjoram and Basil. The upper surface of the leaves is of a pale green, but their under side is hoary and woolly, they are slightly indented on their edges. The flowers grow in flat smooth whorls round the stalks, each stalk hath generally three of these whorls, the upper which terminates the stalk being smaller, the other two increasing, so that the lower is the greatest. The flowers are of a pale purple colour, and shaped like those of the first sort, but the stamina of this stands out beyond the petal, and the bractea at the base of the empalement are large, spear-shaped, and indented on their sides. This plant is called Snake-weed in some parts of America, supposing it a remedy for the bite of rattle snakes. This flowers in July in England.

The third sort grows naturally in Carolina, from whence the seeds were sent me by the late Dr. Dale: this hath a perennial root, which sends up several square stalks, which are closely covered with brownish hairs; these rise between two and three feet high, garnished with leaves which are very unequal in their size, those at the bottom, and also toward the top, being above three inches long, and one inch and a quarter broad, whereas those in other parts of the stalk are not half so large; they are rough on their upper side, hairy below, and sawed on their edges, standing opposite: all the lower part of the stalk, but immediately below the foot-stalks of the flower-heads, there are three large leaves standing round the stalks; between these arise two slender hairy foot-stalks, about three inches long, one on each side the stalk; these sustain small heads of flowers, shaped like those

of the scabious; they are white, shaped like those of the other, but smaller; the bractea immediately under the empalement, spread out like rays. This plant flowers in September in this country; but never ripens its seeds here.

The seeds of the fourth sort were sent me from Carolina, by the late Dr. Dale; this hath some appearance of our common sort, but the stalks do not grow more than half so high, and divide into many long side branches; the leaves are smaller and rougher, and the whorls of flowers are produced half the length of the branches, whereas the common sort hath rarely more than two; the bractea at the base of the empalement is also much longer. This flowers in June and July, and hath a perennial root.

The fifth sort was sent me by the late Dr. Dale, from Carolina; this hath a perennial root, which sends up strait hairy stalks, almost round; the joints of these are four or five inches asunder, at each of these come out two oblong leaves, hairy on their under side, standing upon short foot-stalks; at the bottom of these come out on each side a slender branch, half an inch long, having two or four small leaves, shaped like the other. The flowers are produced in small whorls, standing thinly; these are white, and the bractea are longer than the empalement. This flowers in August.

The sixth sort is a native of Egypt, from whence the seeds were sent to Europe, and the plants have for some years past grown in many curious gardens. It hath a perennial root; the stalks rise a foot and an half high, garnished with oval leaves, having many transverse deep furrows, of a dark green colour; placed opposite, at about five or six inches asunder. There are commonly two or four side branches from the main stem, produced toward the bottom; and the whorls of flowers are produced at every joint toward the upper part of the stalks: these are pretty large and hairy. The flowers are somewhat larger than those of the common Field Basil, and are of a deeper colour, stretching a little more out of the empalement. The leaves of this have at first sight much the same appearance; but when they are observed with attention, the difference is soon observed between the two sorts: but the greatest difference is in the leaves and whorls of flowers being placed at a greater distance, and the stalks growing sparsely in this species; nor do the plants continue so long as those of the common sort.

This sort flowers in June, commonly a fortnight or three weeks before the common Field Basil, and the seeds ripen in September; which, if permitted to scatter, the plants will come up in autumn; and if the winter proves favourable, they will live in the open air, provided they grow on a dry soil; but in moist ground they are frequently destroyed, especially when the plants are young.

This plant approaches near to the *Clinopodium Orientale* *Origanum folio, flore minimo.* Tour. Corol. 12. But by comparing this with a specimen of that sort from the Paris garden, I find the leaves of that are smother, and placed much nearer together on the stalks than those of this sort; the flowers are smaller, so that it may be deemed a distinct species, as these differences are permanent, and do not alter in any of the plants which arise from the seeds.

These plants may be propagated by seeds, and also by parting their roots; the latter is generally practiced in England, because few of the sorts perfect their seeds here. The best time to transplant and part their roots is in autumn, that they may take root before winter. If these are planted in a dry soil, they are all, except the third sort, hardy enough to thrive in the open air in England, and require no other care but to keep them clean from weeds, and every other year they may be transplanted and parted. The third sort must be planted in pots, and in winter sheltered under a frame, where the plants may enjoy the free air in mild weather, but screened from frost, otherwise they will not live in this country.

CLITORIA.

CLITORIA. Lin. Gen. Plant. 796. Ternatea. Tourn. Act. Reg. 1706. Clitorius. Dill. Hort. Elth. 76. We have no English title for this plant.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubular, crested, and indented in five parts at the top. The flower is of the butterfly kind, having a large spreading standard, which is crested, and indented at the top; the two wings are oblong, obtuse, and shorter than the standard, which is closed. The keel is shorter than the wings; it is roundish and hooked; it hath ten stamina, nine of which are joined, and one stands separate, which are terminated by single summits. In the center is situated an oblong germen, supporting a rising style, crowned by an obtuse stigma. The germen afterward becomes a long, narrow, compressed pod, with one cell, opening with two valves, inclosing several kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria; the flowers of this section have ten stamina, which compose two bodies.

The SPECIES are,

1. **CLITORIA** (*Ternatea*) foliis pinnatis. Hort. Cliff. 360. *Clitoria with winged leaves.* Ternatea flore simplici cæruleo. Tourn. Acad. Reg. Sc. 1706.
2. **CLITOREA** (*Brasiliana*) foliis ternatis, calycibus campanulatis solitariis. Hort. Upsal. 215. *Clitoria with trifoliate leaves, and a single flower with a bell-shaped empalement.* Planta leguminosa Brasiliana, Phaseoli flore, flore purpureo maximo. Breyn. Cent. 78. tab. 32.
3. **CLITORIA** (*Virginiana*) foliis ternatis, calycibus campanulatis subgeminis. Flor. Virg. 83. *Three-leaved Clitoria with two flowers joined, whose empalements are bell-shaped.* Clitorius trifolius flore minore cæruleo. Hort. Elth. 90. tab. 76.
4. **CLITORIA** (*Mariana*) foliis ternatis, calycibus cylindricis. Lin. Sp. Plant. 753. *Clitoria with trifoliate leaves, and cylindrical empalements to the flowers.* Clitorius Marianus trifolius subtus glaucis. Pet. Hort. Sicc. 243.

The first sort grows naturally in India; the seeds of this were first brought to Europe from Ternate, one of the Molucca Islands, and this induced Dr. Tournefort to give the title of Ternatea to this genus. There is a variety of this with white flowers, and another with large blue flowers, which make a fine appearance. The seeds which I received of the latter, produced all the plants with very double flowers, without the least variation; but in cold seasons the plants do not produce any pods here.

This rises with a twining herbaceous stalk to the height of four or five feet, in the same manner as the Kidney-bean, and requires the like support; for in the places where it grows naturally, it twists itself about the neighbouring plants; the stalks are garnished with winged leaves, composed of two or three pair of lobes, terminated by an odd one; these are of a beautiful green, and are placed alternate on the stalks; from the appendages of the leaves, come out the foot-stalks of the flower; each of these is encompassed by two very fine leaves about the middle, where they are bent, sustaining a very large, gaping, beautiful flower, whose bottom part seems as if growing to the top.

The flowers have a green membranaceous empalement, which is cut into five parts. The standard of the flowers is large, and is spread open very wide; and the flowers are of so deep a blue colour, as to stain paper, after having been many years dried, almost as blue as indigo; these flowers are succeeded by long slender pods, containing several kidney-shaped seeds.

The second sort grows naturally in the Brasils, from whence these seeds were brought to Europe. This hath a twining stalk like the former, which rises five or six feet high, garnished at each joint with one trifoliate leaf, standing upon a long foot-stalk. The flowers come out singly from the foot-stalk of the leaves, standing upon pretty long foot-stalks, which

are encompassed about the middle with two small oval leaves; the flowers are very large, the standard being much broader than that of the first sort, and the two wings are larger; the flowers are of a fine blue colour, so make a fine appearance. The flowers appear in July, and in warm seasons the seeds will ripen in autumn, soon after which the plants decay.

There is one with a double flower of this sort, which I raised in the Chelsea garden some years past, from seeds sent me from India; but the plants did not produce seeds here, and being annual, the sort was lost. The flowers of this were very beautiful.

The seeds of the third sort were sent me from the Bahama Islands; this sends out from the root two or three slender twining stalks, which rise to the height of six or seven feet, garnished at each joint with one trifoliate leaf, whose lobes are oblong and pointed. At the opposite side of the stalk, the foot-stalk of the flower arises, which is little more than an inch long, naked, and sustains a single flower, which is of a purple colour within, but of a greenish white on the outside, not half so large as either of the former: these flowers are each succeeded by long, slender, compressed pods, ending in a point, which contain one row of roundish kidney-shaped seeds. This sort flowers in July and August, and the seeds ripen in autumn.

The seeds of the fourth sort were sent me from Carolina, where the plants grow naturally. This rises with a twining weak stalk about five feet high, garnished with trifoliate leaves like the former, whose lobes are narrower, and of a grayish colour on their under side; the flowers come out by pairs on the foot-stalks; their empalements are cylindrical. The flowers are small, and of a pale blue colour within, but of a dirty white on the outside. This flowers in August, but rarely ripens any seeds in England.

All these sorts are annual with us in England, so that unless the seeds ripen, the species are lost; and as the two sorts with double flowers have not formed any pods in this country, so far as I have been able to learn, therefore the seeds of these must be procured from the countries where they naturally grow. Indeed these are supposed to be only varieties, which accidentally arise from the single. If this be true, I cannot account for the success of those plants which grew at Chelsea, for they were all of the same double kind, without the least variation; and this was not from a single experiment, but in three different years when I received the seeds, the plants did all of them produce double flowers.

The seeds of these plants must be sown upon a good hot-bed early in the spring; and when the plants are two inches high, they should be carefully taken up, and each planted in a small pot filled with light fresh earth, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root, and refresh them with water as they may require it. After they are well rooted in the pots, they must have air every day in proportion to the warmth of the season, to prevent their drawing up weak; their waterings should be repeated two or three times a week, but they should not have too much at each time. As these plants have climbing stalks, they will soon grow too tall to remain under common frames, therefore they must then be removed into the stove, and plunged into the bark-bed; but if their roots have filled the pots, they should be removed into larger, and afterward they must be treated in the same manner as other plants from the same countries.

CLUSIA. Lin. Gen. Plant. 577. Plum. Nov. Gen. 20. tab. 20. The Balsam-tree.

The CHARACTERS are,

It hath an imbricated empalement, composed of roundish concave leaves which spread open; it hath five or six large, roundish, concave, spreading petals. In the bottom is situated a globular nectarium, including the germen, which is pervious at the top, from which place the stigma arises.

It hath a great number of stamina, which are shorter than the petals, terminated by single summits. The oblong oval germen is terminated by a plain star-like stigma, with six obtuse indentures. The germen afterward becomes an oval capsule, with six furrows, and six cells, opening with six valves, which spread in form of a star, including many angular seeds fixed to a column, surrounded with pulp.

This genus of plants is ranged in the first section of Linnæus's twenty-third class, intitled Polygamia Monœcia, having male, female, and hermaphrodite flowers on the same plant.

The SPECIES are,

1. CLUSIA (*Plava*) foliis aveniis corollis tetrapetalis. Jacq. Amer. 34. *Clusia whose leaves have no veins, and the flower has four petals. Terebinthus folio singulari, non alato, rotundo, succulento flore pallide luteo.* Sloan. Hist. Jam. 2. p. 97. *Commonly called Balsam-tree in America.*

2. CLUSIA (*Veuosa*) foliis venosis. Lin. Sp. Plant. 510. *Clusia with veined leaves. Clusia flore roseo minor, fructu flavescens.* Plum. Nov. Gen. 2.

There are three varieties of the first sort, which differ in the size and colour of their flowers and fruit; one hath a white flower and scarlet fruit, another hath a Rose flower and a greenish fruit, and a third hath a yellow fruit: but these are supposed to be only feminal variations, though Plumier has enumerated them as distinct species; but as the plants have not flowered in England, I can give no particular account of their difference: the singular beauty of the leaves of this plant, renders it worthy of a place in every collection of rare plants.

The first sort is pretty common in the British Islands of America, where the trees grow to the height of twenty feet, and shoot out many branches on every side, garnished with thick, round, succulent leaves, placed opposite. The flowers are produced at the ends of the branches, each having a thick succulent cover: these are of different colours in different plants, some being red, others yellow, some white, and some green. After the flowers are past, they are succeeded by oval fruit, which are also of different colours in different plants: from every part of these trees there exudes a sort of turpentine, which is called in the West Indies Hog-gum; because they say, that, when any of the wild hogs are wounded they repair to these trees, and rub their wounded parts against the stems of them, till they have anointed themselves with this turpentine, which heals their wounds. The turpentine of these trees is also greatly recommended for the cure of sciaticas, by spreading it on a cloth, and applying it as a plaster to the part affected.

The plants are at present very rare in Europe: there were some years ago some fine plants in the garden of Mr. Parker, near Croyden in Surry; these were brought over, growing in tubs of earth from Barbadoes, which is the best method of procuring them; for the seeds seldom succeed, and the young plants grow so slowly, as not to make any figure in some years; but in the bringing over the plants, great care should be had, that they do not receive much wet; for as these plants have very succulent stems, moisture will cause them to rot.

The plants are tender, so they must be constantly kept in the stove, otherwise they will not live through the winter in England; they must also be watered very sparingly, especially in winter, for they naturally grow in those parts of the islands, where it seldom rains, therefore they cannot bear much moisture.

They may be propagated by cuttings, which must be laid to dry when they are cut off from the plants for a fortnight or three weeks, that the wounded part may be healed over, otherwise they will rot. When the cuttings are planted, the pots should be plunged into a hot-bed of tanners bark, and now and then gently refreshed with water: the best time for planting these cuttings is in June or July, that they may

be well rooted before the cold weather comes on in autumn. In winter these plants may be placed upon stands in the dry stove; but if in summer they are plunged into the tan-bed, they will make great progress, and their leaves will be large, in which consists the great beauty of these plants.

The second sort was discovered by the late Dr. Houstoun, growing naturally at Campeachy, from whence he sent me some dried samples and seeds: this hath very large oval spear-shaped leaves, ending in points, which are placed alternate on the branches, and have several ribs, which go off from the midrib alternate, rising upward to the side of the leaves; and also a great number of small veins, running horizontally between these ribs. The borders of the leaves are sawed, and their under sides are of a shining brown colour. The branches are covered with a woolly down, and the flowers are produced in loose spikes at the end of the shoots; these are smaller than those of the former sort, and are of a Rose colour. This tree rises to the height of twenty feet; it is propagated by seeds, which must be obtained from the countries where the trees naturally grow, for there can be little hopes of obtaining any of the seeds in Europe. The plants are tender, so must be placed in the tan-bed of the bark-stove, otherwise they will not thrive in this country; and they must be treated in the same manner as is directed for other tender plants from the same countries.

CLUTIA. This genus of plants was constituted by the learned Dr. Boerhaave, professor of botany in the university of Leyden, in honour of Augerius Clute, a curious botanist.

The CHARACTERS are,

It is male and female in different plants. The male flowers have a large spreading empalement, composed of five oval concave leaves; they have five heart-shaped petals, which are shorter than the empalement, and spread open. They have five exterior nectariums, which are situated in a circle at the bottom of the petals, and five interior, which are situated within the other, having small apices with a mellous liquor, and five stamina situated in the middle of the style, which spread horizontally, terminated by roundish summits: these have no germen, but a long truncated style in the middle of the stamina. The female flowers have permanent empalements, and petals like those of the male; these have five double exterior nectariums, but no interior; they have a roundish germen, supporting three bifid reflexed styles the length of the petals, crowned by obtuse stigma: the germen afterward becomes a globular capsule, with six furrows, and three cells, each containing a single seed.

This genus of plants is ranged in the thirteenth section of Linnæus's twenty-second class, intitled Diccia Gynandria. This section and class include those plants which have the different sexes on separate plants, and the male flowers have their stamina adhering to the style.

The SPECIES are,

1. CLUTIA (*Alaternoides*) foliis sessilibus lineari-lanceolatis floribus solitariis erectis. Hort. Cliff. 500. *Clutia with linear spear-shaped leaves sitting close to the stalks, and solitary erect flowers. Alaternoides Africana telephii legitimi imperati foliis.* Hort. Amst. 2.
2. CLUTIA (*Pulchella*) foliis ovatis integerrimis, floribus lateralibus. Lin. Sp. Plant. 1042. *Clutia with oval entire leaves, and flowers growing from the sides of the branches. Frutex Æthiopicus, portulacæ folio, flore ex albo virescente.* Hort. Amst. 1. p. 177.
3. CLUTIA (*Eleutheria*) foliis cordato lanceolatis. Flor. Zeyl. *Clutia with heart spear-shaped leaves. Ricinus dulcis arborescens Americanus, populneæ frondæ argenteæ.* Pluk. Alm. 321.

The two first sorts are natives of Africa, from whence they were brought to some curious gardens in Holland, and have since been communicated to most of the botanic gardens in Europe. The first sort with male flowers has been long an inhabitant of some curious gardens in England; the other with female flowers has been lately introduced.

Y y y

The

The second sort has also been some years in the English gardens, where we had not that sort with male flowers till lately, when I was favoured with one by my learned friend Dr. Job Baſter, of Zirkzee in Holland.

The first sort riſes with a ſhrubby ſtalk to the height of ſix or eight feet, putting out many ſide branches which grow erect; theſe are garniſhed with ſmall, linear, ſpear-shaped leaves, placed alternate, ſitting cloſe to the branches: they are of a grayiſh colour and entire. The flowers come out from the joints, at the ſetting on of the leaves: toward the upper part of the branches theſe are ſmall and of a greeniſh white; they appear in June, July, and Auguſt, but being ſmall make no great appearance.

The ſecond ſort riſes about the ſame height with the firſt, but hath a ſtronger ſtem; the branches are garniſhed with oval leaves, which are much larger than thoſe of the firſt ſort, ſtanding upon foot-ſtalks which are an inch long; they are of a ſea green, and entire; the flowers are like thoſe of the firſt ſort in ſhape and colour, but thoſe on the male plants are ſmaller, and grow cloſer together than thoſe of the female, but both are ſuſtained upon ſhort foot-ſtalks. Theſe flowers appear at the ſame time as thoſe of the firſt ſort, and the ſeeds ripen in autumn. I have raiſed ſeveral of theſe plants from ſeeds, which have all proved female, the ſame as the parent plant.

Theſe plants are eaſily propagated by cuttings during any of the ſummer months: if the cuttings are planted in ſmall pots, and plunged into a very moderate hot-bed, and ſhaded from the heat of the ſun in the middle of the day, they will ſoon take root, and ſhould then be inured to the open air, otherwiſe they will draw up very weak: afterward theſe plants may be each put into a ſeparate ſmall pot, and placed in a ſheltered ſituation, where they may remain until the middle of Octoſber, or later, if the weather continues mild, when they ſhould be removed into the green-houſe, and placed where they may have the free air in mild weather, for they only require to be protected from froſt, therefore require no warmth in winter; but if the green-houſe is ſhut up too cloſe, or the plants are much ſhaded by others, the tender ſhoots are ſubject to grow mouldy, which deſtroys more of theſe plants than the cold. In ſummer they muſt be placed abroad in a ſheltered ſituation, with other hardy exotic plants.

As theſe plants are always green, they look well in the green-houſe during the winter ſeaſon; and in ſummer, when they are placed in the open air with other exotic plants, they make a pretty variety.

The third ſort grows naturally in India, from whence the ſeeds were brought. This riſes with an upright ſhrubby ſtalk, not more than three or four feet high in England; but in the places where it grows naturally, it riſes upward of twenty feet high, and ſends out many branches at the top, ſo as to form a large ſpreading head: the branches are garniſhed with leaves, ſhaped like thoſe of the black Poplar, which are of a lucid green, and are placed alternate ſtanding upon ſlender foot-ſtalks. As theſe plants have not yet flowered in England, I can give no account of them, but the ſeed-veſſels are very like thoſe of the ſecond ſort.

This plant will live through the winter in an airy glaſs-caſe, without artificial heat; but in that ſituation they ſhould have very little water, for the plants abound with a milky juice like the Euphorbia, ſo muſt at no ſeaſon of the year have too much wet. If theſe plants, when young, are placed in a very moderate warmth in winter, it will greatly forward their growth, but they muſt not have too much heat, for that will force them too much; and when the plants have obtained ſtrength, they may be treated more hardily. This ſort may be propagated by cuttings during the ſummer ſeaſon; but the cuttings ſhould be laid in a dry place for a few days, when they are taken from the old plants, that their wounded parts may dry and be healed over before they are

planted. Theſe muſt be planted in ſmall pots filled with light ſandy earth, and plunged into a moderate hot-bed of tanners bark; and if the ſeaſon is very warm, the glaſſes ſhould be ſhaded in the heat of the day, and raiſed up to admit freſh air to the cuttings every day; theſe muſt be ſparingly watered. When they have taken root, and begin to ſhoot, they muſt have a greater ſhare of air, and by degrees be inured to the open air; and when their roots have filled the pots, they ſhould be carefully parted, and each planted in a ſeparate pot of the ſame light ſandy earth; then they ſhould be placed on the back part of the ſtove, behind the other plants, where they may be ſcreened from the ſun till they have taken freſh root, after which they may be brought forward, and expoſed gradually to the open air. In the ſummer they ſhould have free air conſtantly in warm weather, but they muſt be ſcreened from heavy rain; and in winter placed in an airy glaſs-caſe, where they may enjoy the ſun, and during that ſeaſon have very little wet.

CLYPEOLA. Lin. Gen. Plant. 723. Jonthlaſpi. Tourn. Inſt. R. H. tab. 99. Treacle Muſtard.

The CHARACTERS are,

The flower hath a permanent empalement, composed of four oblong oval leaves. It hath four oblong entire petals, placed in form of a croſs, and ſix ſtamina which are ſhorter than the petals, two of which ſtanding oppoſite are ſhorter than the other, terminated by ſingle ſummits. In the center is ſituated a roundiſh compreſſed germen, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an orbicular pod, which is compreſſed, erect, and indented at the top, with a longitudinal fiſſure, opening in two cells, containing round compreſſed ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, intituled Tetradyamia ſiliculola, the flower having four long and two ſhorter ſtamina, and the ſeeds growing in ſhort pods.

The SPECIES are,

1. CLYPEOLA (*Jonthlaſpi*) ſiliculis unilocularibus monospermis. Hort. Cliff. 329. *Clypeola with pods, having but one cell and a ſingle ſeed.* Jonthlaſpi minimum ſpicatum lunatum. Col. Ecp. 1. *Leaſt Buckler Muſtard with ſpiked flowers.*
2. CLYPEOLA (*Maritima*) ſiliculis bilocularibus ovatis diſpermis. Sauv. Monſp. 71. *Clypeola with oval pods having two cells and two ſeeds.* Thlaſpi Alyſſon dictum maritimum. C. B. P. 107.

This genus of plants was named Jonthlaſpi by Fabius Columna, and the ſame title was continued by Dr. Tournefort, and other late writers on botany before Dr. Linnæus, who has altered the name to this of Clypeola.

The firſt ſort is a low annual plant, which ſeldom riſes more than four inches high; the ſlender branches commonly lie proſtrate on the ground; theſe are garniſhed with ſmall leaves, narrow at their baſe, but are broader at their ends, where they are obtuſe. The flowers are produced in ſhort cloſe ſpikes at the extremity of the branches, which are ſmall, yellow, and compoſed of four petals, placed in form of a croſs; theſe are ſucceeded by orbicular compreſſed ſeed-veſſels, each having one cell, containing a ſingle ſeed. It flowers in June and July, and the ſeeds ripen in autumn.

The ſecond ſort is perennial. This ſends out from the root ſeveral ſlender branches, which divide again into many ſmaller, that lie proſtrate, garniſhed with very narrow hoary leaves, ſitting cloſe to the branches. The flowers are produced in ſpikes at the end of the branches; theſe are ſmall, yellow, and ſhaped like thoſe of the other ſort, but the ſpikes terminate in a roundiſh bunch. It flowers in June, and the ſeeds ripen in autumn.

Theſe two ſorts are low plants, which grow naturally in the ſouth of France, Spain, and Italy, and are preſerved in botanic gardens for the ſake of variety, but have little beauty; their leaves and ſtalks are of a hoary white, which is much lighter in the warm countries

countries than in England; these are propagated by seeds, which should be sown upon a border of light earth where they are to remain, and will require no other culture, but to thin them if they come up too close, and keep them clean from weeds. The seeds may be sown either in the spring or autumn; those which are sown in autumn will grow much larger, and flower earlier than those which are sown in the spring, and from them there will be a greater certainty of having ripe seeds. If the seeds scatter, the plants will come up, and, if kept clean from weeds, they will thrive without farther care.

The second sort is a perennial plant, so should be sown upon a warm border and on a dry soil. This grows naturally on the borders of the sea, in the south of France and Italy; but when it is cultivated in a garden, if the soil is rich and moist, the plants generally grow luxuriant in summer, and are thereby too replete with moisture, so that they are frequently killed by the frost in winter; but when they grow on a poor, dry, gravelly soil, their stalks will be short, ligneous, and tough, so will endure the cold of this climate, and continue several years. This is propagated by seeds, which should be sown where the plants are designed to remain; or if any of them are removed, it should be done when the plants are young, for they do not bear transplanting well, when they are grown pretty large.

CNEORUM. Lin. Gen. Plant. 47. Chamelæa. Tourn. Inst. R. H. 651. tab. 421. Widow-wail.

The CHARACTERS are,

The flower hath a small permanent empalement, inclosed in three parts. It hath three narrow oblong petals, which are erect, and three stamina which are shorter than the petals, terminated by small summits. In the center is situated an obtuse three-cornered germen, supporting a firm erect style, crowned by a trifid spreading stigma. The germen afterward becomes a globular dry berry, with three lobes, having three cells, each containing one round seed.

This genus of plants is ranged in the first section of Linnæus's third class, intitled Triandria Monogynia, the flower having three stamina and one style.

We have but one SPECIES of this genus, viz.

CNEORUM (*Tricoccum*). Hort. Cliff. 18. Widow-wail. Chamelæa Tricoccos of Dodonæus and Caspar Bauhin.

This is an humble shrub, which seldom rises more than two feet and a half high in this country, but spreads out on every side with many lateral branches, so as to form a thick bush. The stems are ligneous, and almost as hard as those of the Box-tree, and the wood is of a pale yellow colour under the bark: the branches are garnished with thick stiff leaves, of an oblong oval shape, about an inch and a half long, and a quarter of an inch broad, of a dark green colour, having a strong vein or rib through the middle. The flowers are produced single from the wings of the leaves, toward the extremity of the branches, which are of a pale yellow colour, composed of three petals, which spread open, and a round germen at the bottom, having a single style, which doth not rise above half the length of the stamina, which are three in number, standing erect, and are situated between the petals. After the flowers are fallen, the germen becomes a fruit, composed of three seeds joined together after the same manner as those of *Tithymalus* or *Spurge*; these are first green, afterwards turn of a brown colour, and when ripe are black. The flowers begin to appear in May, and are succeeded by others during the summer months; and, when the autumn proves favourable, these shrubs will continue in flower till the end of October.

As this is a low evergreen shrub, it may be very ornamental, if placed in the front of plantations of evergreen trees and shrubs; for as the branches grow pretty compact, and are well garnished with leaves, it will hide the ground between the taller shrubs better than most other plants; and, being a durable

shrub, will not want to be removed: it rises better from scattered seeds, than if sown with care.

This was formerly preserved in green-houses, and thought too tender to live in the open air in England; but of late years people have planted it in the full ground, where it resists the cold of our ordinary winters very well, and is seldom injured but by extreme hard frosts; nor do these kill the plants which grow upon dry, rocky, or rubbishing soils, where their shoots are generally short and firm; but in moist rich ground, where the shoots are more luxuriant, they are sometimes injured.

It is propagated by seeds, which should be sown in autumn soon after they are ripe, and then the plants will come up the following spring; whereas those which are not sown till the spring, will remain a year in the ground, and often miscarry: these seeds may be sown in a bed of common earth, covering them half an inch deep, and will require no other care but to keep the plants clear from weeds the following summer; and in the autumn following, the plants may be transplanted where they are to remain.

CNICUS. Lin. Gen. Plant. 833. Tourn. Inst. R. H. 450. tab. 257. Blessed Thistle.

The CHARACTERS are,

The empalement of the flower is composed of many oval scales, placed over each other; those toward the top are terminated by branching spines. The flower is composed of several hermaphrodite florets, which are uniform; these are funnel-shaped, and cut at the top into five equal segments, standing erect, each having five short hairy stamina, terminated by cylindrical summits. In the center is situated a short germen, crowned with down, supporting a slender style, terminated by an oblong stigma. The germen afterward becomes a single seed, crowned with down, and shut up in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Æqualis. The plants of this section have only hermaphrodite flowers, which are fruitful.

The SPECIES are,

1. CNICUS (*Eristibales*) caule erecto, foliis inferioribus laciniatis, superioribus integris concavis. Hort. Cliff. 394. *Cnicus with an upright stalk, whose lower leaves are lacinated, the upper entire and concave.* Cnicus pratensis, Acanthi folio, flore flavescente. Tourn. Inst. 450.
2. CNICUS (*Spinosissimus*) foliis amplexicaulibus, sinuato-pinnatis, spinosis, caule simplici, floribus sessilibus. Lin. Sp. Plant. 826. *Cnicus with winged, sinuated, prickly leaves embracing the stalk, and flowers sitting close on the top.* Cirsium Alpinum spinosissimum, floribus ochroleucis inter flavescentia folia congestis. Haller. tab. 20.
3. CNICUS (*Cernuus*) foliis cordatis, petiolis crispis spinosis amplexicaulibus, floribus cernuis. Hort. Upsal. 251. *Cnicus with heart-shaped leaves, having curled prickly foot-stalks which embrace the stalks, and a nodding flower.* Carduus foliis ex cordato-lanceolatis, margine serratis & spinosis, squamis calycum membranaceis, laceris spinosis, capitulis nutantibus. Flor. Sib. 2. p. 47.

The first sort grows naturally in the northern parts of Europe. Mr. Ray found it growing on the Rhine near Basil. This hath a perennial root, which sends out many long jagged leaves, spreading on every side near the ground, so as to form a thick tuft; these are jagged almost to the midrib, in form of a winged leaf. The stalks are striated, smooth, and rise above four feet high, dividing at the top into smaller branches: the leaves which grow upon the stalks are entire, heart-shaped, concave, and embrace the stalks, and are sawed on their edges, each indenture ending in a weak spine: the stalks are terminated by large heads of flowers, growing in clusters; they are of a whitish yellow colour, and inclosed in a scaly empalement, and are succeeded by small oblong seeds, crowned with a bristly down. It flowers in June, and the seeds ripen in autumn.

This

This sort may be propagated by seeds, or parting the roots; the latter is commonly practised where there are any of the plants, but the seeds are more easily conveyed to a distant place. The best time to part the roots is in autumn; it delights in shade, and requires no farther care but to keep it clean from weeds.

The second sort grows naturally on the Alps, and on the mountains of Austria. This rises with an upright single stalk near four feet high, garnished with sinuated leaves, which are very prickly, and embrace the stalks with their base. The flowers are produced at the top of the stalk, surrounded by a cluster of broad prickly leaves, sitting close to the stalk; they are of a whitish yellow, and appear at the same time with the former sort. It is a perennial plant, which may be propagated in the same manner as the former, and requires a moist soil and a shady situation.

The third sort grows naturally in Siberia, from whence the seeds were sent to the imperial garden at Petersburg, where they succeeded, and produced seeds, part of which were sent me by the professor of botany; this hath a perennial root, composed of thick fleshy fibres. The leaves which rise immediately from the root are near a foot long, and near six inches broad in the middle, diminishing toward each end, and at a little distance from the base are much contracted, but are wider at the end; these have scarce any foot-stalks; they are of a deep green on their upper side, but white on their under, and sharply sawed on their edges. The stalks rise more than six feet high, sending out on each side small branches above a foot long; the stalks are striated, and of a reddish colour; they are garnished with heart-shaped leaves, which almost embrace the stalks with their base, and are of the same colour with those below; each branch is terminated by one large globular head of yellowish flowers, included in a scaly empalement, each scale ending with a sharp spine. This flowers in June, and the seeds ripen in autumn. It may be propagated in the same manner as the two former sorts, but requires a moist soil and shady situation; and if the weeds are kept down, there will be no farther care required. The inhabitants of Siberia eat the tender stalks of this plant, when boiled, instead of other vegetables.

This is a perennial plant, which may be propagated by parting the roots: the best time for doing of this is in autumn, that the plants may get good root in winter; for those which are transplanted in the spring, do not flower well the first year, unless they are planted in a moist soil. As these plants grow very large, they are not proper furniture for small gardens, where they will take up too much room; for they should not be planted nearer than four feet from each other, for if they are too near any other plants, they will rob them of their nourishment; for the roots of these extend to a great distance, so that two or three of these plants, for variety, are sufficient for any garden, which may be planted at a distance from choicer plants.

It is also propagated by seeds, which may be sown in the spring on a bed of common ground, in the same manner as the other sorts; and will only require to be thinned, and kept clean from weeds till autumn, when they may be transplanted where they are designed to remain.

COA. See HIPPOCRATEA.

COAST-MARY. See TANACETUM.

COCCIGRIA. See RHUS.

COCHLEARIA. Lin. Gen. Plant. 720. Tourn. Inst. R. H. 215. tab. 101. [so called of Cochlear, Lat. a spoon, because the leaves of this plant are hollowed like a spoon.] Spoonwort, or Scurvy Grass.

The CHARACTERS are,

The empalement of the flower is composed of four oval concave leaves. The flower hath four petals, placed in form of a cross, which spread open, and are twice as large as the leaves of the empalement; it hath six stamina,

four of which are longer than the other two; these are terminated by obtuse compressed summits. The germen is heart-shaped, supporting a short single style, crowned by an obtuse stigma: this afterward becomes a gibbous, heart-shaped, compressed pod, fastened to the style, having two cells, in each of which are lodged four roundish seeds.

This genus of plants is ranged in the first section of Linnæus's fifteenth class, intitled Tetradyamia Sili-culosa. The flowers of this class have four long and two short stamina, and those of this section have very short pods.

The SPECIES are,

1. COCHLEARIA (*Officinalis*) foliis radicalibus subrotundis, caulinis oblongis subsinuatis. Flor. Lapp. 256. Scurvy Grass whose lower leaves are roundish, and those on the stalks oblong and sinuated. Cochlearia folio subrotundo. C. B. P. 110. Round-leaved Scurvy Grass.
2. COCHLEARIA (*Anglica*) foliis ovato-lanceolatis, sinuatis. Flor. Ang. 248. Scurvy Grass with oval spear-shaped leaves, which are sinuated. Cochlearia folio sinuato. C. B. P. 110. Sea Scurvy Grass.
3. COCHLEARIA (*Grælandica*) foliis reniformibus, carnosiss integerrimis. Hort. Cliff. 498. Scurvy Grass with kidney-shaped leaves, which are fleshy and entire. Cochlearia minima ex montibus Walliæ. Sher. Boerh. Ind. alt. 2. p. 10.
4. COCHLEARIA (*Danica*) foliis hastatis, angulatis. Flor. Suec. 196. Scurvy Grass with angular spear-shaped leaves. Cochlearia Armorica. H. R. Par. Danish, or Ivy-leaved Scurvy Grass.
5. COCHLEARIA (*Armorica*) foliis radicalibus lanceolatis, crenatis, caulinis incisis. Hort. Cliff. 332. Scurvy Grass whose lower leaves are spear-shaped and crenated, and those on the stalks jagged. Raphanus Rusticanus. C. B. P. 96. Horse Radish.
6. COCHLEARIA (*Glaucifolia*) foliis caulinis cordato-sagittatis, amplexicaulibus. Hort. Cliff. 332. Scurvy Grass whose upper leaves are arrow-pointed, heart-shaped, and embrace the stalks. Cochlearia altissima glauci folio. Inst. R. H. 216.

The first sort grows naturally on the sea-shore in the north of England, and in Holland, but is cultivated for use in the gardens near London. This is an annual plant, for the seeds are sown, and the plants decay within the compass of one year, but the seeds should be sown early in autumn; this hath a fibrous root, from which arise many round succulent leaves, which are hollowed like a spoon; the stalks rise from six inches to a foot high; these are brittle, and garnished with leaves, which are oblong and sinuated. The flowers are produced in clusters at the end of the branches, consisting of four small white petals, which are placed in form of a cross, and are succeeded by short, roundish, swelling seed-vessels, having two cells, divided by a thin partition; in each of these is lodged four or five roundish seeds. It flowers in April, and the seeds ripen in June, soon after which it decays.

This sort is propagated in gardens for medicinal uses, which is done by sowing the seeds in July, soon after they are ripe, in a moist shady spot of ground; and when the plants are come up, they should be thinned, so as to be left at about four inches distance each way. The plants that are taken out may be transplanted into other shady borders, if there is occasion for them, otherwise they may be hoed out (as is practised for Onions, Carrots, &c.) and at the same time all the weeds may be hoed down, so as to clear the plants entirely from them, that they may have room to grow strong. In the spring these plants will be fit for use; and those that are suffered to remain will run up to seed in May, and perfect their seeds in June. If this plant is sown in the spring, the seeds seldom grow well, therefore the best time is soon after they are ripe. The plants rarely live after producing seeds, so that it should be sown every year, to have it for use.

The Sea Scurvy Grass is also used in medicine; but this grows in the salt marshes in Kent and Essex, where

C O C

where the salt water overflows it almost every tide, and can rarely be made to grow in a garden, or at least to last longer there than one year; but it being easily gathered in the places before-mentioned, the markets are supplied from thence by the herb-women, who make it their business to gather herbs.

This sort differs from the first in the shape of its leaves, these being longer, and sinuated on their edges. It flowers a little later in the season; both these sorts are used in medicine.

The little Welch Scurvy Grass is a biennial plant, and may be preserved in a garden, if planted in a strong soil and a shady situation. This is preserved in curious gardens of plants, but is not of any use in medicine, though it is by far the warmest and most pungent of all the sorts. This grows plentifully in Mulcovy, as also in Davis's Streights.

The fourth sort is a low trailing plant, whose stalks grow six inches long, and lie prostrate on the ground; the leaves are angular, and in shape like those of Ivy. This is found growing naturally in some parts of England, and is annual. It flowers and seeds about the same time as the first sort.

The sixth sort is a biennial plant, which usually grows about a foot and a half high, with upright stalks, garnished with angular heart-shaped leaves, embracing the stalks with their base; the flowers are produced in loose spikes at the end of the branches; they are very small, white, and are succeeded by short swelling pods filled with round seeds. It flowers in May, and the seeds ripen in July and August. This may be propagated by seeds as the common sort; and if sown in autumn, will more certainly succeed than in the spring.

The Horse Radish is propagated by cuttings or buds from the sides of the old roots. The best season for this work is in October or February; the former for dry lands, the latter for moist; the ground should be trenched at least two spits deep, or more if it will allow of it. The manner of planting it is as follows: provide yourself with a good quantity of offsets, which should have a bud upon their crowns, but it matters not how short they are; therefore the upper part of the roots which are taken up for use, may be cut off about two inches long with the bud to it, which is esteemed the best for planting. Then make a trench ten inches deep, in which you should place the offsets at about four or five inches distance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a second trench in like manner, and continue the same till the whole spot of ground is planted. After this, level the surface of the ground even, observing to keep it clear from weeds, until the plants are so far advanced, as to be strong enough to overbear and keep them down. With this management the roots of the Horse Radish will be long and strait, and free from small lateral roots, and the second year after planting will be fit for use. 'Tis true, they may be taken up the first year, but then the roots will be but slender; therefore it is the better way to let them remain until the second year. The ground in which this is planted ought to be very rich, otherwise the roots will make but a small progress.

COCOS. Lin. Gen. Plant. 1223. The Cocoa Nut.

The CHARACTERS are,

There are male and female flowers on the same tree. The universal spathe has one valve. The empalement consists of three small-coloured concave leaves; the flower has three oval spreading petals, and six stamina the length of the corolla, terminated by triangular summits. The germen is scarce discernible, supporting three short styles, crowned by obsolete stigma; these are barren. The female flowers are included in the like spathe. The empalement is three-leaved, which is coloured and permanent; they have three petals to the flowers, which are larger than the empalement, and an oval germen without a style, with a three-lobed stigma. The nut is large, triangular, and is perforated by three holes at the end.

This genus is placed by Linnaeus in his appendix un-

C O C

der the title of Monoica Hexandria, the same plants having hermaphrodite and female flowers, the hermaphrodite having six stamina.

We know but one SPECIES of this genus, viz.

Cocos (Nucifera) frondibus pinnatis, foliolis ensiformibus replicatis. Jacq. Hist. 168. Cocoa Nut with winged branches, whose small leaves are sword-shaped and folded. Palma Indica coccifera angulata. C. B. P. 502.

This tree is cultivated in both Indies, but is generally supposed to grow naturally in the Maldives, and other desert islands of the East-Indies. The trees grow to a great height in their native places, but their stems are composed of strong fibres like net-work, which lie in several lamina over each other, out of which come the branches (or rather leaves,) which grow twelve or fourteen feet long. The midrib is garnished with sword-shaped small leaves, whose borders fold backward: the first leaves which push out from the nut when planted, are very different from those which are afterward produced; for they are very broad, and have many folds in each: whereas, the after leaves have a strong midrib, of great length, on which the smaller lobes are placed alternately; these lobes are from six to eight or nine inches long, and are almost triangular, having very sharp points, and are very stiff. The flowers come out round the top of the trunk of the tree in large clusters; they are inclosed in a large spathe or sheath, and the nuts afterward are formed in large clusters; these are included in large net-work covers, which adhere closely about them; the nut has a hard shell, with three holes at the upper end. The kernel is large, sweet, and the lower part of the shell, when first taken from the tree, is filled with a pale liquor, which the inhabitants of the countries where the trees grow, call milk, and they are very fond of it. From this milk I have been informed by persons of credit, there has been exceeding good arrack distilled in Jamaica.

The plants are propagated by planting the nuts in such places where they are designed to remain; for the plants will not bear transplanting, unless it is performed while they are very young, for their roots shoot deep and wide; so that if these are cut or broken, the plants seldom survive it, which is generally the case with most of the kind of Palms.

Where any persons are desirous of having a plant or two of this sort, they should procure some fresh nuts from the nearest place of their growth, which, on their arrival in England, should be buried in a warm bed of tanners bark, laying them on one side, that the young shoot which comes out from one of the three holes may not be injured by wet, covering them about six inches deep with the tan. In this situation, if the nuts are good, they will put out shoots in six weeks or two months, so should be then carefully taken up, and each planted in a separate pot filled with kitchen-garden earth, and plunged into the tan-bed in the stove, where the plants should always remain, for they are too tender to thrive in any other situation; but as the plants advance in their growth, they should be shifted into larger pots or tubs, being careful not to cut or tear their roots in the operation.

This is one of the most useful trees to the inhabitants of America, who make many necessary utensils from the several parts of it. The outer cover of the nuts is made into cordage; the shells are converted into drinking bowls; the kernel of the nuts affords them a wholesome food, and the milk a cooling liquor. The leaves of the tree are used for thatching of their houses, and are also wrought into baskets, and many other things which are made of Osiers in Europe.

COCCOLOBA, Sea-side Grape.

The CHARACTERS are,

The empalement is of one leaf, cut into five parts, which spread open and are permanent. The flower has no corolla, but hath eight awl-shaped spreading stamina, terminated by roundish twin summits. It has an oval three-cornered germen, supporting three short spreading styles, crowned by simple stigmas. The empalement afterward becomes a thick berry, inclosing an oval-

Z z z.

pointed

C O C

pointed nut, with one cell, having a single seed of the same form.

This genus of plants is ranged in the third section of Linnæus's eighth genera, intitled *Oständria Trigynia*, the flowers having eight stamina and three styles.

The SPECIES are,

1. *CoccoLOBA (Uvifera)* foliis cordato-subrotundis nitidis. Lin. Sp. 523. *Sea-side Grape with neat, roundish, heart-shaped leaves.* Guajabara racemosa, foliis coriaceis subrotundis. Plum. Nov. Gen.
2. *CoccoLOBA (Rubescens)* foliis orbiculatis pubescentibus. Lin. Sp. 523. *Sea-side Grape with orbicular hairy leaves.* Scortea arbor Americana, amplissimis foliis averfa parte nervis extantibus. Pluk. Phyt. 222. f. 8.
3. *CoccoLOBA (Punctata)* foliis lanceolato-ovatis. Lin. Sp. 523. *Sea-side Grape with oval spear-shaped leaves.* Uvifera arbor Americana, fructu aromatico punctato. Pluk. Alm. 394.
4. *CoccoLOBA (Excoriato)* foliis ovatis, ramis quasi ex-corticatis. Lin. Sp. 524. *Sea-side Grape with oval leaves, and the branches casting their bark.* Guajabara alia racemosa, foliis oblongis. Plum. Icon. 146. f. 1. Called *Mountain Grape*.
5. *CoccoLOBA (Tenuifolia)* foliis ovatis membranaceis. Amœn. Acad. 5. p. 397. *Sea-side Grape with oval membranaceous leaves.*

The first sort rises with many ligneous stems to the height of ten or twelve feet, having several knots or joints, covered with a gray bark: at each joint is set on one large, roundish, smooth leaf, a little indented at the top. The flowers come out from the foot-stalks of the leaves, in long bunches like those of Currants; they have no petals, but the empalement is cut into five segments, including eight awl-shaped stamina, terminated by twin summits. The germen afterward becomes a succulent berry, including an oval-pointed nut, having one seed of the same form.

The second sort seldom rises so high as the first, but divides into several lateral branches, garnished with large roundish leaves, having several deep veins; the flowers and fruit come out from the side of the branches in like manner as those of the first, but are larger.

The third sort is a lower shrub than either of the former; the leaves are oval and spear-shaped; the fruit is smaller, somewhat aromatic, and spotted; these proceed from the side of the branches in like manner as the former sorts.

The fourth sort grows to a much larger size than any of the other; the leaves of this are much larger, of an oblong oval form, very smooth, and of a lucid green: from the wings of the leaves, the flowers and fruit are produced, which are in form like those of the other sorts, but are larger.

The fifth sort is of humbler growth than either of the former; the leaves are membranaceous, of an oval form; the flowers and fruit are smaller than those of the other sorts. These plants all grow naturally in the warm islands of America; some of them on the sea-shores, where they form very close, almost impenetrable thickets; the fruit of the first sort are frequently eaten by the inhabitants of the islands, but especially by the negroes. Those of the other sorts are food for birds.

The plants of all the sorts are easily propagated by seeds, when they can be obtained fresh from the places of their natural growth (for none of the sorts have as yet produced either fruit or flowers in England.)

The seeds should be sown in small pots filled with earth from the kitchen-garden, and plunged into a hot-bed. If the seeds are good, and the bed of a proper temperature of warmth, the plants will appear in five or six weeks after, which will be fit to transplant in about a month after; when they should be shaken out of the pots, separating their roots carefully, and each planted in a separate small pot filled with the like earth, plunging them into a hot-bed of tanners bark, being careful to shade them in the day-time, until they have taken new root; after which they

C O F

should be treated in the same way as other tender exotic plants, which require to be kept constantly in the bark-stove.

CODLIN-TREE. See *MALUS*.

COFFEA. Lin. Gen. Plant. 209. Juss. Act. Reg. Scien. 1713. *Jasminum*. Com. Cat. The Coffee-tree.

The CHARACTERS are,

The flower hath a small empalement divided into four parts, sitting upon the germen. It hath one petal which is funnel-shaped, having a narrow cylindrical tube, which is much longer than the empalement, but is plain at the top, where it is indented in five parts. It hath five stamina which are fastened to the tube, and are terminated by long slender summits. The roundish germen supports a single style, crowned by two thick reflexed stigmas. The germen afterward becomes an oval berry, containing two hemispherical seeds, plain on one side, and convex on the other.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled *Pentandria Monogynia*, the flower having five stamina and one style; it hath been generally included in the genus of *Jasmines*; but as the flowers of *Jasmine* have but two stamina, so by Linnæus's system, this is separated and ranged in another class.

We have but one SPECIES of this genus, viz.

COFFEA (Arabica.) Hort. Cliff. 59. The Coffee-tree. *Jasminum Arabicum Castaneæ folio, flore albo odoratissimo, cujus fructus Coffea in officinis dicuntur nobis.* Juss. Act. Par. 1713.

This tree is supposed to be a native of Arabia Felix, where it was first cultivated for use, and to this day, is the country from whence the best Coffee is brought to Europe, though the plant is now propagated in many parts of India and America; but the produce of those countries being greatly inferior to that of Arabia, hath occasioned its present disrepute in England, so that it is scarce worth importing; but this might be remedied, if the Coffee planters in the West Indies could be prevailed on to try a few experiments, which I shall hereafter propose, being founded on those which have been made in England, upon the berries produced here. But I shall first treat of the plant, with its culture in England.

This is a low tree in the native country of its growth, where it seldom rises more than sixteen or eighteen feet high, but in England I have not seen any above ten or twelve. The main stem grows upright, and is covered with a light brown bark; the branches are produced horizontally and opposite, which cross each other at every joint, so that every side of the tree is fully garnished with them: the lower branches being the longest, the others gradually decreasing to the top, form a sort of pyramid; the leaves are also produced opposite; these when fully grown, are about four or five inches long, and one inch and a half broad in the middle, decreasing toward each end; the borders are waved, and the surface is of a lucid green. The flowers are produced in clusters at the base of the leaves, sitting close to the branches; these are tubulous, spread open at the top, where they are divided into five parts, and are of a pure white, with a very grateful odour, but of short duration: they are succeeded by oval berries, which are first green, when fully grown, they turn red, and afterward change to black when fully ripe; these have a thin pulpy skin, under which are two seeds joined, which are flat on the joined sides, with a longitudinal furrow, and convex on their outer side.

As the Coffee-tree is an Evergreen, it makes a beautiful appearance at every season in the stove, but particularly when it is in flower; and also when the berries are red, which is generally in the winter; so that they continue a long time in that state, therefore there is scarce any plant that more deserves a place in the stove than this.

It is propagated by the berries, which must be sown soon after they are gathered from the trees, for if they are kept out of the ground a short time they will not grow. I have frequently sent the berries abroad

by

by the post, but when they have been a fortnight in their journey they have all failed; and this has constantly happened every where, for the berries which were sent from Holland to Paris did not grow, nor did those which were sent from Paris to England grow; so that wherever these trees are desired, the young plants must be sent, if it be at any distance from the place where they grow.

The berries should be planted in small pots, filled with light kitchen-garden earth, and plunged into a hot-bed of tanners-bark; the pots must be watered gently once or twice a week, but the earth must not be too moist, lest it rot the berries. If the bed be of a proper temperature of warmth, the plants will appear in a month or five weeks time, and in about two months more will be fit to transplant. For as many of the berries will produce two plants, so the sooner they are parted, the better their roots will be formed; for when they grow double till they have made large roots, they will be so intermixed and entangled, as to render it difficult to separate them without tearing off their fibres, which will greatly prejudice the plants. When these are transplanted, they must be each put into a separate small pot, filled with the same earth as before, and plunged into the tan-bed again; which should be stirred up to the bottom, and if required, some new tan should be mixed with it, to renew the heat. Then the plants should be gently watered, and the glasses of the hot-bed must be shaded every day till they have taken new root; after which the plants should have free air admitted to them every day, in proportion to the warmth of the season: during the summer they will require frequently to be refreshed with water, but they must not have it in too great plenty: for if their roots are kept too moist, they are very subject to rot, then the leaves will soon decay and drop off, and the plants become naked; when this happens, they are seldom recovered again. The first sign of these plants being disordered, is, their leaves sweating out a clammy juice, which attracts the small insects, that too frequently infest the plants in stoves; when they are not in health, these insects cannot be destroyed, till the plants are recovered to vigour: for although the plants are ever so carefully washed and cleaned from them, yet they will be soon attacked by them again, if they are not recovered to health, for these insects are never seen upon any of the plants while they are in perfect vigour; but when they are disordered, they soon spread over all the leaves and tender parts of the plants, and multiply exceedingly; so that upon the first attack, the plants should be shifted into fresh earth, and all possible care taken to recover them, without which all the washing and cleaning of the plants will be to little purpose. The disorders attending the Coffee-trees, generally proceed from either being put into pots too large for them, nothing being of worse consequence than over potting them; or from the earth being too stiff, or overhung by other plants, or being over watered. If these are properly taken care of, and the stove kept always in a proper temperature of heat, the plants will thrive, and produce plenty of fruit.

I have made trial of several compositions of earth for these plants, but have found none of them equal to that of a kitchen-garden, where the soil is naturally loose, and not subject to bind; and if it has constantly been well wrought and properly dunged, this without any mixture is preferable to any other.

The plants should not be too often transplanted, for that will greatly retard their growth. If they are new potted twice a year at most, it will be sufficient; though unless the plants make great progress, they will not require to be removed oftener than once in a year, which should be in summer, that they may have time to get good roots again before winter. During the warm weather in summer, these plants should have a large share of air, but they must not be wholly exposed abroad at any season: for although they may have the appearance of thriving in the open air

during the heat of summer, yet when they are removed into the stove again, their leaves will fall off, and the plants will make but an indifferent appearance the following winter, if they should survive it: therefore it is the better method to keep them constantly in the stove, and admit a proportionable share of air to them every day, according to the heat of the season; they will require water two or three times a week in warm weather, but in the winter they must have it more sparingly; and the stove in which they are placed, should be kept to the heat assigned for the Ananas upon the botanical thermometers.

There has been some of these plants propagated by cuttings, and also from layers; but these are long before they make roots, and the plants so raised, are never so strong and thriving as those which arise from berries; therefore where the berries can be procured, it is much the best method to propagate the plants by seeds.

When the plants are transplanted, their roots should not be too much cut or trimmed; the decayed or rotten fibres should be pruned off, and those which are closely matted to the side of the pots should be trimmed, but not cut too near to the stem; for the old fibres do not put out new roots very kindly, especially those which are become tough, so that there should always be a sufficient number of young fibres left to support the plants, till new ones are produced.

The Coffee plants were first carried from Arabia to Batavia by the Dutch, and from thence they were afterward brought to Holland, where great numbers of the plants were raised from the berries which those plants produced, and from these most of the gardens in Europe have been furnished. A great number of these young plants, which were raised at Amsterdam, were sent to Surinam by the proprietors of that island, where the trees were soon propagated in great plenty, and from thence the plants have been dispersed to most of the islands in the West Indies: for as the plants raised from the berries, produce fruit in two years from planting, and in the warm countries sooner, so plantations of these trees may be soon made in any of those countries, where the temperature of the air is proper for their production, but the trees will not grow in the open air any where if there is a winter: so that in all countries without the tropics, they cannot be expected to grow abroad.

The French have made great plantations of these trees in their settlements in the West Indies, and also in the isle of Bourbon, from whence they import great quantities of Coffee annually to France; which although greatly inferior in quality to the Arabian, yet it is consumed, otherwise they would not continue that branch of commerce. In the British colonies of America, there have been some large plantations made of Coffee-trees: and it was proposed to the parliament, some years past, to give a proper encouragement for cultivating this commodity in America, so as to enable the planters to undersell the importers of Coffee from Arabia. Accordingly there was an abatement of the duty payable on all the Coffee which should be of the growth of our colonies in America, which at that time was supposed would be a sufficient encouragement for the planters to improve this branch of commerce: but the productions of those countries, being greatly inferior in quality to that of Arabia, hath almost ruined the project; and unless the planters can be prevailed on to try some experiments to improve its quality, there can be little hope of its becoming a valuable branch of trade; therefore I shall beg leave to offer my sentiments on this article, and sincerely wish what I have to propose may be found useful for the instruction of the Coffee planters; for as my opinion is founded upon experiments, so it is not mere theory or supposition.

The great fault of the Coffee which grows in America, and also in the isle of Bourbon, is the want of flavour, or having a disagreeable one. The berries

are

are much larger than those which are imported from Arabia, and consequently have not so much spirit or flavour. This may be owing to several causes, the first is that of its growing in a soil too moist; which is always known to increase the size of fruit and vegetables, but their quality is greatly diminished thereby. The second is from the gathering of the berries too soon; for I have been credibly informed, that it is the constant practice of the planters, to gather the fruit when it is red: at which time the berries are much larger, and of greater weight, than those which are permitted to ripen perfectly on the trees, which is not till they are turned black, and their outer pulp becomes dry, and the skins shrink: then the berries are much smaller than before, and the outer cover will easily separate from the berry; which I have always been informed, has been the complaint of the planters, that this was with great difficulty and trouble effected. A third cause I imagine may be in the drying of the berries when gathered; which must be constantly attended to, for they cannot be too much exposed to the sun and air in the day time, but they must be every evening removed under cover, and carefully screened from dews and rain; nor should they be placed near any sort of liquid or moisture, for these berries are very subject to imbibe moisture, and thereby acquire the flavour of the liquid; or if it be pure water, the berries will be enlarged, and the flavour diminished by it, as from many experiments I can affirm: for a bottle of rum being placed in a closet, in which a canister of Coffee berries closely stopped, was standing on a shelf at a considerable distance, in a few days had so impregnated the berries, as to render them very disagreeable; the same also has happened by a bottle of spirits of wine standing in the same closet with Coffee and Tea, both which were in a few days spoiled by it. Therefore from many experiments of this nature, which I have made with Coffee, it appears to me that it should never be brought over in ships freighted with rum, nor should the berries be laid to dry in the houses where the sugars are boiled, or the rum distilled. I have also been informed by a gentleman who has a very good estate in Jamaica, and who has lived many years in that island, that the planters frequently boil the Coffee berries before they are dried. As this information comes from a gentleman of great skill and veracity, so I cannot doubt of the fact; and if so, this alone is sufficient to spoil the best Coffee in the world; so that I am at a loss to guess the reason for this practice, which, as it appears to me, can only be intended to increase the weight, therefore must be imputed to avarice, the bane of every public good.

There was some time past an imperfect account printed in the papers, of the cause why the American Coffee was not so good as that which comes from Arabia; in which it is supposed, that the goodness of the latter proceeded from the length of time which the berries had been kept: therefore the author proposes that the American Coffee berries should be many years kept, which he says will render them equally good. This is contrary to all the experience I have had, or can learn, from those who have seen the whole progress of Coffee in Arabia, with their manner of drying and packing it to send abroad; for two gentlemen who had lived there some years assured me, that the berries, when first gathered, were much better than those which are kept any time. And a curious gentleman who resided in Barbadoes two years, also told me, that he never drank better Coffee in any part of the world, than what he made from the fresh berries which he gathered himself, and roasted as he had occasion for them; which is also confirmed by the trials which have been made with the berries which grow in the stoves in England, which make a better flavoured liquor, than the best Arabian Coffee berries which can be procured in England; therefore I wish those who are inclinable to cultivate these trees in America, would make

choice of a soil rather dry than moist, in which the trees will not make so great progress as those which grow in a wet soil, nor will the produce be so great; but as the quality of the produce will be so much improved, it will certainly be of greater advantage to them.

The next thing is, to permit the berries to remain so long upon the trees, till their skins are shrivelled and turned very black; which it is true will greatly diminish their weight, but then the commodity will be more than double the value of that which is gathered sooner.

When the berries are fully ripe, they should be gathered, or rather shaken from the trees, when they are perfectly dry, and spread abroad upon cloths in the sun to dry, carrying them every evening under cover, to prevent the dews from falling on them, or the rain if any should happen: and when they are perfectly dry, they should be carefully packed up in cloths or bags, three or four times double, and consequently kept in a dry situation: and when they are shipped for England, it should be on board those vessels which have no rum, lest the Coffee should imbibe the flavour, which cannot be prevented when stowed in the same place. For some years past, a Coffee ship from India had a few bags of pepper put on board, the flavour of which was imbibed by the Coffee, and the whole cargo spoiled thereby.

As the quantity of Coffee now consumed in Britain is very much increased of late years, so it will certainly be worthy of public consideration, how far it may be necessary to encourage the growth of it in the British colonies: and certainly it deserves the attention of the inhabitants of those colonies, to improve this commodity to the utmost of their power, and not to have so much regard to the quantity, as to the quality of it; for although the former may appear to have the advantage of the latter in point of profit, yet the goodness of every commodity must always claim the preference, and thereby will be found of more lasting advantage to the cultivator.

COIX. Lin. Gen. Plant. 927. Lachryma Jobi. Tourn. Inst. R. H. 531. tab. 306. Job's Tears.

The CHARACTERS are,

It hath male and female flowers on the same plant; the male flowers are disposed in a loose spike; the chaff of these have two valves, inclosing two flowers, the valves are oblong and bearded; the petal has two oval valves, the length of the chaff, with narrow beards: these have each three hairy stamina, terminated by oblong four-cornered summits. There are a few female flowers situated at the base of the male spike in the same plant, these have bivalvular chaff; the valves are roundish, thick, and smooth; the petal hath two oval valves, the outer being larger and bearded at both ends. They have a small oval germen, supporting a short style divided into two parts, crowned by two horned stigmas which are longer than the flower, and covered with fine hairs; the germen afterward becomes a hard, roundish, smooth seed.

This genus of plants is ranged in the third section of Linnæus's twenty-first class, intitled Monœcia Triandria. The plants of this class have male and female flowers on the same plant, and the flowers of this section have three stamina.

The SPECIES are,

1. Coix (*Lachryma Jobi*) feminibus ovatis. Hort. Cliff. 434. Coix with oval seeds. Lachryma Jobi. Clus. Hist. p. 2. Job's Tears.

2. Coix (*Angulatis*) feminibus angulatis. Hort. Cliff. 438. Coix with angular seeds. Lachryma Jobi Americana altissima, Arundinis folio & facie. Plum. Cat.

The first sort grows naturally in the islands of the Archipelago, and is frequently cultivated in Spain and Portugal, where the poor inhabitants grind the grain to flour in a scarcity of corn, and make a coarse sort of bread of it.

This is an annual plant, which seldom ripen its seeds in England, unless the season proves very warm; from a thick fibrous root is sent out two or three jointed stalks, which rise near three feet high, garnished

nished with single, long, narrow leaves at each joint, resembling those of the Reed; at the base of the leaves come out the spikes of flowers, standing on short foot-stalks; these spikes are composed of male flowers only, and below them is situated one or two female flowers; the male flowers decay soon after they have shed their farina; but the germen of the female flowers swell to a large oval seed, which is hard, smooth, and of a gray colour, greatly resembling the seeds of Gromwel, from whence this plant has been by several writers titled Lithospermum.

Those who are desirous to cultivate this plant in England, may procure the seeds from Portugal, these should be sown on a moderate hot-bed in the spring, to bring the plants forward, and afterward transplant them on a warm border, allowing each two feet room at least, and when the plants have taken root, they will require no farther care, but to keep them clean from weeds. These will flower about Midsummer, and in warm seasons, the seeds will ripen at Michaelmas. There is a variety of this with much broader leaves, which I received from Smyrna some years past, which did not perfect seeds here, so I cannot say whether it is only a variety, or a different sort from this.

The second sort will grow to the height of seven or eight feet, and the stems become hard, like the Reed, or Indian Corn: these branch out, and produce several spikes of flowers; but this sort will not live in the open air in England, therefore should be plunged into the bark-stove, where it will live through the winter, and produce ripe seeds the second year; and may be continued longer, if desired.

COLCHICUM. Lin. Gen. Plant. 415. Tourn. Inst. R. H. 348. tab. 181, 182. [So called from Colchos, a province of the Levant (now called Mingrelia, because this plant was formerly very common in that place.) Meadow Saffron.

The CHARACTERS are,

The flower hath neither empalement or spathe; it hath one petal, rising with an angular tube from the root, which is divided at the top into six oval, concave, erect segments; it hath six stamina which are shorter than the petal, terminated by oblong summits having four valves. The germen is situated in the root, supporting three slender styles the length of the stamina, crowned by reflexed channelled stigmas; the germen afterward becomes a capsule with three lobes, having a seam on the inside, dividing it into three cells, which contain several roundish rough seeds.

This genus of plants is ranged in the third section of Linnæus's sixth class, intitled Hexandria Trigynia, the flower having six stamina and three styles.

The SPECIES are,

1. **COLCHICUM** (*Autumnale*) foliis planis lanceolatis, erectis. Hort. Cliff. 140. *Colchicum with plain, erect, spear-shaped leaves.* Colchicum commune. C. B. P. 67. *Common Meadow Saffron.*
2. **COLCHICUM** (*Montanum*) foliis linearibus, patentissimis. Lin. Sp. Plant. 342. *Meadow Saffron with very narrow spreading leaves.* Colchicum Montanum angustifolium. C. B. P. 68. *Narrow-leaved Mountain Meadow Saffron.*
3. **COLCHICUM** (*Variegatum*) foliis undulatis patentibus. Hort. Cliff. 140. *Meadow Saffron with waved spreading leaves.* Colchicum Chionense, floribus fritillariæ instar tessulatis, foliis undulatis. Mor. Hist. 2. p. 341. *Meadow Saffron of Chios, with chequered flowers like Fritillary, and waved leaves.*
4. **COLCHICUM** (*Tessulatum*) foliis planis patentibus. Colchicum with plain spreading leaves. Colchicum floribus fritillariæ instar tessulatis, foliis planis. Mor. Hist. 2. p. 341. *Meadow Saffron, with chequered flowers like Fritillary, and plain leaves.*

There is a greater variety of these flowers than any here enumerated, which differ in the colour of their flowers, and other little accidents, which are not lasting, so must not be ranged as distinct species. But as many of them are cultivated in flower-gardens, I shall beg leave to mention those varieties, which

are frequently propagated by florists. These are most of them seminal variations from the first sort.

The most common Meadow Saffron hath a purplish flower.

The Meadow Saffron with white flowers.

Meadow Saffron with striped flowers.

Broad-leaved Meadow Saffron.

Striped-leaved Meadow Saffron.

Many flowered Meadow Saffron.

Meadow Saffron with double purplish flowers.

Meadow Saffron with double white flowers.

Meadow Saffron with many white flowers.

The first sort grows naturally both in the west and north of England. I have observed it in great plenty in the meadows near Castle Bromwich, in Warwickshire, in the beginning of September. The country people call the flowers Naked Ladies, because they come up naked, without any leaves or cover. This hath a bulbous root, about the size and shape of those of the Tulip, but not so sharp-pointed at the top, the skins or cover is also of a darker colour. These bulbs are renewed every year, for those which produce the flowers decay, and new roots are formed above. The flowers come out in autumn; these arise with long slender tubes from the root, about four inches high, shaped like those of the Saffron, but larger; they are of a pale purple colour, and divided into six parts at the top, which stand erect; the number of flowers is generally in proportion to the size of the roots, from two to seven or eight: in March the green leaves appear, these are commonly four to a full grown root; they are folded over each other below, but spread open above ground, standing cross-ways: they are of a deep green, and when fully grown, are five or six inches long, and one and a half broad. The seed-vessel comes out from between the leaves in April, and the seeds ripen in May, soon after which the leaves decay.

The other varieties of this, are supposed to have accidentally risen from the seeds of this; so that those who are desirous to obtain a variety of these flowers, should propagate them from seeds, by which method there may be a greater variety raised.

The second sort grows naturally on the mountains in Spain and Portugal. This hath a smaller root than the first, and a darker coat; the flowers appear in August or September; these are cut into six long narrow segments, of a reddish purple colour, having six yellow stamina. The leaves of this sort come up soon after the flowers decay, and continue green all the winter, like the Saffron; these are long, narrow, and spread on the ground; in June these decay like the first sort.

The third and fourth sorts grow naturally in the Levant, but are commonly cultivated in the English gardens. These flower at the same time as the first sort, and the green leaves come up in the spring. The root of one of these species, is supposed to be the Hermodactyl of the shops.

These are all very pretty varieties for a flower-garden, producing their flowers in autumn, when few other plants are in beauty; and are therefore, by some, called Naked Ladies. The green leaves come up in the spring, which are extended to a great length in May, then the green leaves begin to decay; soon after which time, is the proper season to transplant their roots; for if they are suffered to remain in the ground till August, they will send forth fresh fibres; after which time it will be too late to remove them. The roots may be kept above ground until the beginning of August; at which time, if they are not planted, they will produce their flowers as they lie out of the ground, but this will greatly weaken their roots. The manner of planting their roots being the same as Tulips, &c. I shall forbear mentioning it here, referring the reader to that article: and also for sowing the seeds, by which means new varieties may be obtained, I shall refer to the article XI-PHION; where will be proper directions for this work.

C O L D signifies something devoid of heat, or which does not contain in it any particles of fire; according to which definition, cold is a mere negative term. And this is agreeable to the sentiments of most of our modern philosophers, who suppose cold to consist in a mere privation or diminution of heat.

Others much on the same principle, define cold, to be that state of the minute parts of a body, wherein they are agitated more slowly and faintly than those of the organs of feeling. And in this sense, cold is a mere term of relation: and hence the same body becomes liable to be perceived hot or cold, as the particles of it are in greater or lesser degree of motion than those of the sensible organ.

Heat is supposed to consist in a particular motion of the parts of the body; and hence the nature of cold, which is its opposite, is easily deducible; for we find that cold extinguishes, or rather abates heat. Whence it seems to follow, that those bodies are cold, which check and restrain the motion of the particles, wherein heat consists.

There are three kinds of bodies that can do this; viz. either those whose particles are perfectly at rest; or those whose particles are indeed agitated, but with less violence than those of the hot body to which they are applied; or, lastly, such whose particles have a motion proper for exciting the sensation of heat, but move with a different determination, so as to retard and change the motion of the particles of the organ.

Hence three different kinds of cold, or cold bodies, do proceed.

The 1st, That cold is common to all hard bodies; which consists in the rest of their parts.

The 2d is, That which rises from plunging any part of the body in water; which consists in this, that the parts of our præcordia, being more briskly agitated than those of the fluid, communicate part of their motion to it.

The 3d, The cold felt on the collection of warm air with a pan, or in blowing hot breath out of our mouth with the lips close shut; which consists in this, that the direct motion of the particles of air does, in some measure, change and rebate the motion and determination of the parts of the body: and hence it is, that a cold body cannot cool another without heating itself.

Hence also it proceeds, that the more the parts of a frigid body are at rest, the more the particles of a warm body that is applied to heat them, must lose of their motion, and consequently of their heat.

Thus, there being more quiescent parts in marble than in wood, which is full of pores and interstices, the marble is felt colder than the wood: and hence also we may understand why air near marble, and other dense bodies, feels somewhat colder than in other places.

On this principle the two latter kinds of cold appear somewhat more than privations: the particles inducing the cold may be esteemed real frigorific corpules; and coldness may be deemed a real quality, as well as hotness. These particles do not only check the agitation of those continually diffused from the inner parts of an animal to the outer; but having an elastic power, they bend, and hang about the filaments of the body, pinch and squeeze them; and hence is that acute pungent sensation called cold.

That cold is more than a mere relation or comparison, is evident from its having real and positive effects; such as freezing, congelation, condensation, rarefaction, bursting, &c.

Dr. Clarke takes cold to be owing to certain nitrous and other saline particles, endued with particular figures proper to produce such effects. Hence sal-armoniac, salt petre, salt of urine, and many other volatile and alkalizate salts, mixed with water, increase its degree of cold very sensibly.

Hence also comes that popular observation, that cold prevents corruption; which, however, must not be admitted without an exception; since if an hard po-

rous body have its interstices filled with water, and this be too much dilated by freezing, the including body will be burst. And thus it is that cold proves destructive to the parts of some plants: as it happened in the winters, anno 1728, and 1739-40, in several trees, whose trunks were much exposed to the south-west, the sap being thereby rarefied by the warmth of the sun, which, for several days, at the beginning of the severe frost, shone with an uncommon heat, and the nights coming on to extreme cold, whereby the rarefied sap was so suddenly condensed, that the sap-vessels could not contain it, and thereby burst off the bark of many trees almost from top to bottom; and this chiefly on the south-west side of the trees; as it did of several large trees in the physic-garden at Chelsea; and several Pear, and other fruit-trees, in the nurseries of Mr. Francis Hunt at Putney, &c. And thus it is that great quantities of trees are rendered shaken, and the timber, when cut, of little value; which is generally the case in very severe winters. In the hard frost of the year 1739-40, there was great damage done to the Oak-timber in most parts of England, by the frost penetrating to the sap-vessels of the trees; and by freezing the sap, the vessels could not contain it, but burst with great noise; so that the woods resounded with a noise somewhat like the breaking down of the branches of trees, when they are lopping.

Dr. Boerhaave says, That there is no such thing in all nature as absolute cold; that the most severe he had ever known, was in the year 1728, that then the water would freeze while it ran down his hand; and yet even then the cold was not so complete, but that he could make an artificial cold greater by twelve degrees.

Though much might be said as to the effects of cold on plants, I shall only conclude with an observation of the Reverend Dr. Hales, who, in the conclusion of his excellent treatise of Vegetable Statics, says;

The considerable quantity of moisture, which is perspired from the branches of trees during the cold winter season, plainly shews the reason why, in a long season of cold north-easterly winds, the blossoms, and tender young-set fruit and leaves, are, in the early spring, so frequently blasted, viz. by having the moisture exhaled faster than can be supplied from the trees; for, doubtless, moisture rises slower from the root, the colder the season is, though it rises, in some degree, all the winter; as is evident, as he says, from his sixteenth experiment in the said book.

And from the same cause it is, that the leafy spires of Corn are by these cold drying winds often faded, and turned yellow; which makes the husbandman, on these occasions, wish for snow: which, though it be very cold, yet it not only defends the root from being frozen, but also screens the Corn from these drying winds, and keeps it in a moist, florid, supple state.

It seems therefore to be a reasonable direction, which some authors, who write on agriculture and gardening give, viz. During these cold drying winds, when little dew falls, to water the trees in dry soils, in the blossoming season, and while the young-set fruit is tender; and provided there is no immediate danger of a frost, or in case of continued frost, to take care to cover the trees well, and at the same time to sprinkle them with water; which is imitating nature's method of watering every part.

As to sloping shelters over wall-trees he says; I have often found, that when they are so broad, as to prevent any rain or dew coming at the trees, they do more harm than good in these long easterly drying winds, because they prevent the rain and dews falling on them; which would not only refresh and supple them, but also nourish them: but in case of sharp frost after a shower of rain, these shelters and other fences must needs be of excellent use to prevent the almost total destruction occasioned by the freezing of the tender parts of vegetables, when they are saturated with moisture.

C O L D E N I A.

COLDENIA. Lin. Gen. Plant. 159. This plant was so titled by Dr. Linnæus, in honour of Dr. Colden, of North America, who is a very curious botanist, and has discovered several new plants which were not known before.

The CHARACTERS are,

The empalement of the flower is composed of four erect leaves, which are as long as the petal. It hath a funnel-shaped flower of one petal, spreading at the top, and obtuse; it hath four stamina, which are inserted in the tube of the petal, terminated by roundish summits. In the center is situated four oval germen, each supporting a hairy style the length of the stamina, crowned by permanent stigmas. The germen afterward become an oval, compressed, rough fruit, with four cells, terminated by four beaks, inclosed by the empalement, each of the cells containing a single seed, convex on one side, and angular on the other.

This genus of plants is ranged in the third section of Linnæus's fourth class, intitled Tetrandria Tetragynia, the flower having four stamina and four styles.

There is but one SPECIES of this genus, viz.

COLDENIA (*Procumbens*). Flor. Zeyl. 79. This is by Dr. Pluknet titled, *Teucris facie bisnagarica tetracoccus rostrata*. Alm. 363.

This is a native of India, from whence the seeds have been brought to some of the curious botanic gardens. It was sent me by Dr. Linnæus, professor of botany at Upsal in Sweden. It is an annual plant, whose branches trail on the ground; they extend near a foot from the root, and divide into many smaller branches, garnished with short leaves, sitting close to them; these are deeply crenated on their edges, and have several longitudinal veins; they are of a glaucous colour, and come out without order. The flowers are produced at the wings of the leaves, growing in small clusters; these have one funnel-shaped petal cut into four segments at the top; they are of a pale blue colour, and very small; they have four stamina and four styles, having hairy stigmas. When the flower decays, the germen becomes a fruit, composed of four cells, wrapped up in the empalement, each containing a single seed.

This plant is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each put into a separate small pot, plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root; after which they should have air admitted to them every day in proportion to the warmth of the season, and gently watered two or three times a week in warm weather, but they must not have too much moisture. These plants must remain in the hot-bed, where they will flower in June, and the seeds will ripen in September.

COLEWORTS. See BRASSICA.

COLLINSONIA. Lin. Gen. Plant. 38. The title of this plant was given to it by Dr. Linnæus, in honour of Mr. Peter Collinson, F. R. S. a most distinguished promoter of botanical studies, and the first who introduced this plant, among many others, to the English gardens.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five equal segments at the top, the three upper being reflexed, and the two under erect. The flower is funnel shaped, of one petal which is unequal, and much longer than the empalement, cut into five parts at the top, the upper being short and obtuse, two of them being reflexed; the lower lip or beard is longer, ending in many points. It hath two long bristly stamina which are erect, terminated by incumbent summits. It hath a quadrifid obtuse germen, with a large gland, supporting a bristly style the length of the stamina, crowned by a pointed bifid stigma. The germen afterward becomes a single roundish seed, situated in the bottom of the empalement.

This genus of plants is ranged in the first section of Linnæus's second class, intitled Diandria Monogynia, the flower having two stamina and one style.

We have but one SPECIES of this plant, viz.

COLLINSONIA (*Canadensis*) foliis cordatis oppositis. *Collinsonia with heart-shaped leaves growing opposite.*

This plant was brought from Maryland, where it grows wild, as it also does in many other parts of North America, by the sides of ditches, and in low moist ground, where it usually rises to the height of four or five feet; but in England it seldom grows above three feet high, and unless it be planted in a moist warm situation, or in dry weather is duly watered, it rarely flowers well; therefore many people keep the plants in large pots, for the more convenient watering them, but these plants seldom produce good seeds; whereas those which are planted in the full ground, and are constantly watered, will ripen seeds very well in good seasons.

This hath a perennial root. The stalks decay in the autumn, and fresh shoots come out in the spring. The stalks are square, garnished with heart-shaped leaves, placed opposite, which are sawed on their edges. The flowers are produced at the extremity of the stalks in loose spikes; these have long tubes, and are divided into five parts at the top; they are of a purplish yellow, and the lower segment is terminated by long hairs. The flowers appear in July, and the seeds ripen in autumn.

This plant may be easily propagated by parting the roots in October. These roots should be planted at three feet distance, for they require much nourishment, otherwise they will not thrive. This plant will live in the open ground, if it is planted in a sheltered situation.

COLOCASIA. See ARUM.

COLOCYNTHIS. See CUCURBITA.

COLUMBINE. See AQUILEGIA.

COLUMNÆA. Plum. Nov. Gen. 28. tab. 33.

Lin. Gen. Plant. 710. The title of this genus was given to it by Plumier, in honour of Fabius Columna, a nobleman of Rome, who has published two curious books of botany.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five parts at the top; it hath one petal, of the (ringent) or grinning kind, having a long swelling tube, divided above into two lips, the upper being erect, concave, and entire; the lower is divided into three parts which spread open: it hath four stamina, two being longer than the other; these are inclosed in the upper lip, and are terminated by single summits. In the center is situated the roundish germen, supporting a slender style, crowned by a bifid acute stigma. The germen afterward becomes a globular berry with two cells, sitting on the empalement, and is of the same magnitude, containing several oblong seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia. The flowers of this class have two long and two short stamina, and those of this section have their seeds inclosed in a capsule.

We have but one SPECIES of this plant in the English gardens, viz.

COLUMNÆA (*Scandens*). Lin. Sp. Plant. 638. *Columnæa scandens*, Phœniceo flore, fructu albo. Plum. Nov. Gen. 28. *Climbing Columnæa with a scarlet flower and a white fruit.* Plumier mentions a variety of this, with a yellowish flower and a white fruit. But this is only a seminal variation supposed to have accidentally risen from the seeds of the first.

I received seeds of the scarlet sort from Carthage in New Spain, where the plants grew naturally. This hath a climbing stalk, which fastens itself to the neighbouring plants, whereby it is supported. The leaves are oval, sawed on their edges, and stand upon short foot-stalks; these, and also the stalks, are very hairy; but the plants decayed the following year, before they produced any flowers, so that I can give no description of them.

These plants are natives of the warmest parts of America, so are too tender to live in England, unless they are preserved in the stove; they are propagated by

by seeds, which must be sown in a good hot-bed; and when the plants come up, they must be treated in the same way as other tender exotic plants which are kept in the bark-stove.

COLUTEA. Tourn. Inst. R. H. 649. tab. 417. Lin. Gen. Plant. 776. Bladder Sena.

The CHARACTERS are,

It hath a bell-shaped permanent empalement of one leaf, indented in five parts. The flower is of the butterfly kind. The standard, wings, and keel, vary in their figure in different species. It hath ten stamina, nine of which are joined, the other stands separate, which are terminated by single summits. In the center is situated an oblong germen, which is compressed, supporting a rising style, crowned by a bearded line, extended from the middle of the upper part of the style. The germen afterward becomes a broad swollen pod with one cell, including several kidney-shaped seeds.

This genus of plants is ranged in Linnæus's third section of his seventeenth class, intitled Diadelphia Decandria. The flowers of this class have ten stamina, nine of which are joined, and the tenth stands separate.

The SPECIES are,

1. COLUTEA (*Arborescens*) arborea, foliolis obcordatis. Hort. Cliff. 365. Tree Bladder Sena with heart-shaped lobes. Colutea vesicaria. C. B. P. 396. Common Bladder Sena.
2. COLUTEA (*Istria*) foliolis ovatis, integerrimis, caule fruticoso. Shrubby Bladder Sena with oval leaves which are entire.
3. COLUTEA (*Orientalis*) foliolis cordatis minoribus, caule fruticoso. Bladder Sena with smaller heart-shaped leaves, and a shrubby stalk. Colutea Orientalis flore sanguinea coloris, lutea macula notato. Tourn. Cor. 44.
4. COLUTEA (*Frutescens*) fruticosa foliolis ovato-oblongis. Hort. Cliff. 366. Shrubby Bladder Sena with oblong oval leaves. Colutea Æthiopica flore Phœniceo, folio Barbæ Jovis. Breyn. Cent. 1. 73. Æthiopian Bladder Sena with a scarlet flower.
5. COLUTEA (*Americana*) foliolis ovatis, emarginatis, leguminibus oblongis compressis acuminatis, caule arboreo. Bladder Sena with oval leaves indented at the top, oblong, compressed, pointed pods, and a tree-like stalk. Colutea Americana, vesiculis oblongis compressis. Houst. MSS. American Bladder Sena with oblong compressed pods. Dr. Pluknet titles it Colutea Veræ Crucis vesicaria. Alm. 111. pl. 165. f. 3. Bladder Sena of Vera Cruz.
6. COLUTEA (*Herbacea*) herbacea foliolis linearibus. Hort. Upsal. 266. Herbaceous Bladder Sena with narrow leaves. Colutea Africana annua, foliolis parvis, mucronatis, vesiculis compressis. Hort. Amst. 2. p. 87. tab. 44.
7. COLUTEA (*Procumbens*) caulibus procumbentibus, foliolis ovato-linearibus, tomentosis, floribus alaribus pedunculis longissimis. Bladder Sena with trailing stalks, oval narrow leaves which are woolly, and flowers growing from the sides of the stalks, with very long foot-stalks.

The first sort is commonly cultivated in the nursery-gardens, as a flowering shrub, to adorn plantations. This grows naturally in Austria, in the south of France and Italy, from whence the seeds were originally brought to England; this hath several woody stems, which grow to the height of twelve or fourteen feet, sending out many woody branches, garnished with winged leaves, composed of four or five pair of oval lobes, placed opposite, terminated by an odd one; these are indented at the top in form of a heart, and are of a grayish colour. The flowers come out from the wings of the leaves upon slender foot-stalks, about two inches long, each sustaining two or three flowers of the butterfly kind, whose standard is reflexed and large. The flowers are yellow, with a dark-coloured mark on the petal; these are succeeded by inflated pods an inch and a half long, having a seam on the upper side, containing a single row of kidney-shaped seeds, fastened to a placenta. This

flowers in June and July, and the seeds ripen in autumn. There is a variety of this with reddish pods, which is equally common in the gardens, and is supposed to be only an accidental variety, for the plants do not differ in any other part.

The seeds of the second sort were brought from the Levant by the Reverend Dr. Pocock, which succeeded in the garden at Chelsea; and since Dr. Russel, who resided many years at Aleppo, brought over dried samples of this sort, which he assures me grow common near that city. This sort seldom grows more than six or seven feet high; the branches are very slender, and spread out on every side, garnished with winged leaves, composed of nine pair of small, oval, entire lobes, terminated by an odd one; the flowers stand upon slender foot-stalks, about the same length of the former. The flowers are also like those, but are of a brighter yellow. This sort begins to flower early in May, and continues flowering till the middle of October.

The third sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the royal garden at Paris, where they succeeded, and since have been communicated to most of the curious gardens in Europe. This hath a woody stem, which sends out many branches on every side, which do not rise above seven or eight feet high; these are not so strong as those of the first sort, and are garnished with winged leaves, composed of five or six pair of small heart-shaped lobes, terminated by an odd one. The flowers proceed from the side of the branches, standing upon foot-stalks, each sustaining two or three flowers, shaped like those of the first sort, but smaller; they are of a dark red colour, marked with yellow: these appear in June, and the seeds ripen in autumn.

The fourth sort grows naturally in Æthiopia, from whence the seeds were brought to Europe. This hath a weak shrubby stalk, which sends out side branches, growing erect, garnished with equal winged leaves, composed of ten or twelve pair of small, oval, oblong, hoary lobes. The flowers are produced at the upper part of the branches from the wings of the leaves, each foot-stalk sustaining three or four scarlet flowers, which are longer than those of the other sorts, and are not reflexed; these are succeeded by inflated pods, containing one row of kidney-shaped seeds. The usual time of this plant producing its flowers is in June; but when the seeds are sown early in the spring, the plants frequently flower the following autumn.

The fifth sort was sent me from La Vera Cruz, in New Spain, in the year 1730, by the late Dr. Houstoun. This hath a shrubby stalk, which rises to the height of twelve or fourteen feet, sending out many branches, garnished with winged leaves, composed of three pair of oval lobes, terminated by an odd one; these are indented at the top, and are of a light green. The flowers are of a bright yellow, and stand two or three upon each foot-stalk, and are succeeded by compressed winged pods near four inches long, which end in long points.

The sixth sort grows naturally at the Cape of Good Hope. This is an annual plant of little beauty, so is rarely cultivated but in botanic gardens for the sake of variety. It rises with a slender herbaceous stalk about a foot and a half high, dividing upward into three or four branches, garnished with winged leaves, composed of five or six pair of very narrow lobes an inch long, which are a little hoary. The flowers are small, of a purplish colour, standing three together on slender foot-stalks, which are succeeded by flat oval pods, each containing two or three kidney-shaped seeds. It flowers in July, and the seeds ripen in autumn, and the plant decays soon after.

The seeds of the seventh sort were sent me from the Cape of Good Hope, in 1753, which have succeeded in the garden at Chelsea. This plant hath many slender ligneous stalks, which trail on the ground, and

are divided into many smaller branches, garnished with winged leaves, composed of twelve or fourteen pair of small, narrow, oval lobes, terminated by an odd one; these, and also the stalks, are covered with a whitish down. The flowers are very small, of a purple colour, and stand upon very long slender foot-stalks, each sustaining three or four flowers; these are succeeded by compressed pods little more than half an inch long, which are a little bent like a sickle, each containing a single row of small kidney-shaped seeds. It flowers in June and July, and the seeds ripen in autumn. This is a perennial plant, which, if sheltered in the winter, will continue several years; but the branches do not extend more than a foot in length, and unless they are supported, always trail upon the ground.

The three first mentioned sorts are very hardy shrubs, which thrive in the open air extremely well, so are generally propagated for sale in the nursery-gardens; but the first sort hath been longer in England, so is more generally known and propagated than either of the other, which have been but few years in the English gardens, nor has the third sort been long known in this country. This is not mentioned in any of the botanic books; but as the seeds ripen here very well, in a few years it may be in as great plenty as the first sort.

The three first sorts are propagated by sowing their seeds any time in the spring, in a bed of common earth; and when the plants are come up, they must be kept clear from weeds; and the Michaelmas following they should be transplanted either into nursery rows, or in the places where they are designed to remain; for if they are let grow in the seed-bed too long, they are very subject to have downright tap-roots, which renders them unfit for transplantation; nor should these trees be suffered to remain too long in the nursery before they are transplanted, where they are to remain for the same reason.

The first sort will grow to the height of twelve or fifteen feet, so is very proper to intermix with trees of a middling growth in wilderness quarters; or in clumps of flowering trees, where the oddness of their flowers and pods will make a pretty variety, especially as these trees continue a long time in flower; for they usually begin flowering by the end of May, and from that time to September they are seldom destitute of flowers, but especially the second sort.

These shrubs make great shoots annually, which are frequently broken down by strong winds in the summer; so that if they are not sheltered by other trees, their branches should be supported, otherwise they will be broken and split off, whereby the trees will be rendered unsightly.

The third sort does not grow so tall as the common, but makes a more regular shrub and is less liable to split. The flowers of this sort are of a dusky red colour, spotted with yellow, so it makes a very pretty variety, and is as hardy as the common sort, therefore may be propagated by seeds in the same manner.

The fourth sort is tender, so will not live through the winters (when they are severe) in the open air in England; but in mild winters, if they are planted in a dry soil and a warm situation, they will thrive very well; and those plants which live abroad will flower much stronger, and make a finer appearance, than those which are preserved in the green-house; for these plants require a large share of air, otherwise they are apt to draw up weak, so seldom produce their flowers in plenty; therefore when any of the plants are sheltered in winter, they must be placed as near the window as possible, that they may have all the advantages of air; and in the spring they must be hardened, to bear the open air as soon as possible.

This sort is propagated by seeds as the former. If the seeds are sown early in the spring upon a warm border of light earth, the plants will flower in August; and, if the autumn proves favourable, they will sometimes ripen their seeds very well; but there are some persons who sow the seeds upon a moderate

hot-bed in the spring, whereby they bring their plants so forward as to flower in July, whereby the seeds are generally perfected from these plants. When the plants are transplanted, it should always be done while they are young, for they do not bear removing when they are large. This sort will sometimes live in the open air for three or four years, when they stand in a well sheltered situation; and these will grow to have large heads, and make a very fine appearance when they are in flower; they will also continue much longer in beauty than those plants which are treated more tenderly.

The fifth sort grows naturally in warm countries, so is too tender to thrive in the open air in England. It is propagated by seeds, which must be sown on a hot-bed in the spring; and when the plants are two inches high, they should be each transplanted into a separate small pot filled with light earth, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root; after which they must be treated in the same way as other plants from the same climate, always keeping them in a stove, which should be of a moderate temperature of heat.

The sixth sort is a low annual plant, which seldom grows more than a foot and a half in height; the flowers being small, and having little beauty, it is seldom preserved but in botanic gardens. The seeds of this sort must be sown upon a moderate hot-bed in the spring, and the plants must be planted into small pots, and brought forward in another hot-bed. In July they will flower, when they may be exposed in the open air, in a warm situation, where the seeds will ripen in September, and the plants will soon after decay.

The seventh sort may be raised on a moderate hot-bed in the spring, and afterward exposed to the open air in summer; but in winter they must be sheltered under a frame, otherwise the frost will destroy them.

COLLIFLOWER. See BRASSICA.

COLUTEA SCORPIOIDES. See EMERUS.

COMA AUREA. See CHRYSOCOMA.

COMARUM. Lin. Gen. Plant. 563. Pentaphylloides. Tourn. Inst. R. H. 298. Marsh Cinquefoil.

The CHARACTERS are,

The flower hath a large spreading empalement of one leaf, divided into ten parts at the top, which is coloured. It hath five oblong petals, which are inserted in the empalement, but are much smaller. It hath twenty or more permanent stamina, which are inserted into the empalement, terminated by moon-shaped summits. It hath a great number of small roundish germen collected into a head, having short single styles arising from their sides, which are crowned by single stigmas. The common receptacle afterward becomes a large fleshy fruit, having many pointed seeds adhering to it.

This genus of plants is ranged in the fifth section of Linnaeus's twelfth class, intitled Icosandria Polygynia, the flower having many stamina and a great number of styles.

We know but one SPECIES of this genus, viz.

COMARUM (Palustre). Fl. Lapp. 214. Pentaphylloides palustre rubrum. Inst. R. H. 298. *Red Marsh Bastard Cinquefoil*; and the *Quinquefolium palustre rubrum*. C. B. P. 326. *Red Marsh Cinquefoil*.

There is another variety of this, which grows plentifully in Ireland, and also in several places in the north of England, from whence I have procured many of the plants, which after one year's growth in the garden, have been so like the common sort, as not to be distinguished from it; so that the different appearance which it has in the places where it grows naturally, may be supposed to arise from the soil and situation. This is by Dr. Plukenet titled *Pentaphylum palustre rubrum, crassis & villosis foliis Succicum & Hibernicum*. Alm. 284. *Red Marsh Cinquefoil of Sweden and Ireland, with thick and hairy leaves.*

This plant hath creeping woody roots, which send out many black fibres, penetrating deep into the ground, from which arise many herbaceous stalks about

two feet high, which generally incline to the ground; these are garnished at each joint with one winged leaf, composed of five, six, or seven lobes, which rise above each other, the middle being the largest; the lower diminishing, and with their base embrace the stalks; these are deeply sawed on their edges, smooth above, of a light green, and hoary on their under side. The flowers are produced at the top of the stalks, three or four together on short foot-stalks; these have a large spreading empalement, which is red on the upper side, and divided at the top into ten parts; in the center sits the five petals, which are red, and not more than a third part the size of the empalement; within these are situated many germen, attended by twenty or more stamina, terminated by dark summits. After the flower is past, the receptacle which sits in the bottom of the empalement, becomes a fleshy fruit, somewhat like a Strawberry, but flatter, including a great number of pointed seeds. It flowers in July, and the seeds ripen in autumn.

As these plants are natives of bogs, they are with difficulty preserved in gardens, for they must be planted in a soil as near to that of their natural growth as possible; they are very apt to spread much at the root, when in a proper situation: so whoever is inclinable to preserve these plants, may remove them from the places of their growth in October; and if they are planted on a bog, there will be no danger of the plants succeeding. There are a few of these plants now growing upon a bog at Hampstead, which were planted there some years ago; but the nearest place to London, where they grow wild in plenty, is in the meadows near Guilford in Surry.

COMMELINA. Lin. Gen. Plant. 58. Plum. Nov. Gen. 48. tab. 38. Zanonina. Plum. Nov. Gen. 38. tab. 38. This plant was so called by father Plumier, from Dr. Commeline, a famous professor of botany at Amsterdam.

The CHARACTERS are,

It hath a permanent spathe, which is large, heart-shaped, compressed, and shut together. The flower hath six concave petals, three or four of which are small and oval, (these are frequently taken for the empalement) the other are large, roundish, and coloured. It hath three nectariums, (which have been supposed to be stamina;) these have proper stamina, which sit horizontal, and are shaped like a cross. There are three awl-shaped stamina, which recline, and sit about those of the nectarium, which are terminated by oval summits. In the center is situated a roundish germen, supporting a twining style, crowned by a single stigma. The germen afterward becomes a naked globular capsule, with three furrows, having three cells, each containing two angular seeds.

This genus of plants is ranged in the first section of Linnæus's third class, intitled Triandria Monogynia, the flower having three stamina and one style; to this genus he has joined the Zanonina of Plumier, which was separated by that author from Commelina, because the flower has three petals, and his Commelina but two; whereas the several species of this genus most of them differ in the number of their petals, some having two green, and four coloured petals, others are equal, and some have four green, and but two coloured petals.

The SPECIES are,

1. COMMELINA (*Communis*) corollis inæqualibus, foliis ovato-lanceolatis, acutis, caule procumbente, glabro. Hort. Upsal. 18. *Commelina with unequal petals, oval, spear-shaped, pointed leaves, and a smooth trailing stalk.* Commelina procumbens annua, saponariæ folio. Hort. Elth. 93. tab. 78.
2. COMMELINA (*Erecta*) corollis inæqualibus, foliis ovato-lanceolatis, caule erecto, scabro, simplicissimo. Hort. Upsal. 18. *Commelina with unequal petals, oval spear-shaped leaves, and a single, upright, rough stalk.* Commelina erecta, ampliore subcæruleo flore. Hort. Elth. 94. tab. 78.
3. COMMELINA (*Africana*) corollis inæqualibus, foliis lanceolatis, glabris, obtusis, caule repente. Lin. Sp.

Plant. 41. *Commelina with unequal petals, smooth, spear-shaped, obtuse leaves, and a creeping stalk.* Commelina procumbens, flore luteo. Prod. Leyd. 538.

4. COMMELINA (*Tuberosa*) corollis æqualibus, foliis ovato-lanceolatis, subciliatis. Hort. Upsal. 18. *Commelina with equal petals, and oval spear-shaped leaves, which are hairy on their under side.* Commelina radice anacampserotidis. Hort. Elth. 94. tab. 79.

5. COMMELINA (*Zanonina*) corollis æqualibus, pedunculis incrassatis, foliis lanceolatis, vaginis laxis marginibus hirsutis bracteis geminis. Lin. Sp. Plant. 61. *Commelina with equal petals, thick foot-stalks to the flower, spear-shaped leaves, a loose hood, and double bractes.* Zanonina graminea perfoliata. Plum. Nov. Gen. 38.

There are some other species of this genus, but those which are here enumerated, are all that I have seen growing in the English gardens.

The first sort grows naturally in the islands in the West-Indies, and also in Africa; this is an annual plant, which hath several trailing stalks, that put out roots at the joints, which strike into the ground; at each joint is placed one oval spear-shaped leaf, ending in a point, embracing the stalk with its base, and hath several longitudinal veins: they are of a deep green, and smooth. The flowers come out from the bosom of the leaves, included in a spathe, which is compressed and shut up, each having two or three flowers, standing upon short foot-stalks, composed of two large blue petals, and four small green ones, which have generally been termed the empalement of the flower; within these are situated three nectariums, each having a slender stamina fixed on the side; these surround the germen, which afterward becomes a roundish capsule having three cells, in each of these is lodged two angular seeds. It flowers in June and July, and the seeds ripen in autumn. This plant was titled Ephemerum flore dipetalo, by some of the older writers on botany.

The second sort grows naturally in Pennsylvania, from whence I received the seed; this hath a perennial root, composed of many white fibres; the stalks rise a foot and a half high, are upright, rough, herbaceous, and about the size of quills; these have a single leaf at each joint, shaped like those of the first sort, and embrace the stalks with their base; the flowers come out from the bosom of the leaves at the upper part of the stalk, sitting upon short foot-stalks; they are of a pale bluish colour, and are succeeded by seeds as the first sort. This flowers about the same time with the first, but the seeds do not often ripen in England.

The third sort grows naturally in Africa; this hath a fibrous root, which sends out many trailing stalks three feet long, which send out roots at every joint, and from them many more shoots are produced; so that where the plants are in a proper degree of warmth, and have room to spread, they will cover a large surface of ground. The leaves of this sort are very like those of the first, but the flowers are larger and of a deep yellow colour; the petals of this are heart-shaped, and the seed-vessels are larger. This flowers in July, and the seeds ripen in autumn.

The fourth sort grows naturally near Old Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houstoun. This hath a thick fleshy root composed of several tubers, somewhat like those of Ranunculus, several joining together at the top, where they form a head, and diminish gradually downward; from this arise one or two inclining stalks, which send out side branches from their lower parts; these are garnished with oval spear-shaped leaves, part of which have long foot-stalks, the others embrace the stalks with their base; they have short hairs on their under side, and toward the stalk, but are smooth above, of a deep green colour, and close every evening, or in cold weather. The flowers are produced toward the upper part of the stalks, from the bosom of the leaves, standing upon slender foot-stalks; these are composed of three blue petals which are pretty

pretty large and roundish, and three smaller which are green; the seeds are like those of the other sorts. It flowers in June, July, and August, and the seeds ripen in autumn, soon after which the stalks decay, but the roots may be preserved two or three years, if they are planted in a stove in winter.

The fifth sort grows naturally in the West-Indies; the seeds of this were sent me from the island of Barbuda. This hath trailing stalks like the first, which are garnished with narrow grassy leaves, embracing the stalks with their base; the flowers are produced at the end of the stalks, upon thick foot-stalks, three flowers generally sitting on each. The flowers have three equal large petals of a sky blue, and three smaller which are green. These flower in July and August, but have not perfected seeds in England.

All the sorts are propagated by seeds; the first will grow if sown in the full ground; but if the seeds are sown upon a warm border of light earth in autumn, the plants will rise early in the spring; so from these goods seeds may be expected, if the season proves favourable; whereas those which are sown in the spring, often lie long in the ground, so rarely ripen their seed. These plants have but little beauty, so that two or three of each sort, is as many as most people choose to have; therefore if the seeds are sown in autumn where the plants are designed to remain, or the seeds permitted to scatter, the plants will require no farther care, but to keep them clear from weeds. The second sort hath a perennial root; this seldom ripens seeds in England, but the roots send out offsets, by which the plant is easily propagated. But it is too tender to live in the full ground in winter, unless it has a warm sheltered situation; therefore should be planted in pots, and sheltered under a common frame in winter, and exposed abroad in summer; the best time to transplant and part these roots is about the end of March.

The other sorts are tender, so their seeds must be sown on a moderate hot-bed in the spring, and when the plants are two inches high, they should be transplanted to a fresh hot-bed to bring the plants forward; when they have taken fresh root, they should have a large share of fresh air admitted to them every day in warm weather, to prevent their growing weak; and in June these may be carefully taken up, and transplanted on a warm border of light earth, observing to shade them till they have taken fresh root; after which they will require no other care, but to keep them clean from weeds. With this management the plants will flower and produce good seeds.

The third and fourth sorts may be continued, if they are planted in pots, and in autumn placed in the bark-stove; or if the roots of the fourth sort are taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the spring, placing them on a hot-bed to forward their shooting, and these will produce stronger plants than those which rise from seeds.

COMMONS and COMMON-FIELDS. See **LAND.**

COMPARTMENTS are beds, plats, borders, and walks, laid out according to the form of the ground, and ingenuity of the artist, and depend more on a good fancy than any rules. These are diversified in knots, flower-gardens, or parterres, of which there are great variety, and may be diversified infinitely, according to the fancy of the designers.

Plain compartments are pieces of ground divided into equal squares and flower-beds, marked out by the line, of equal length and breadth.

Some persons allow to these squares, borders of two feet in breadth, and not more, if the plat of ground be small; but if they be reasonably large, three feet; and they edge the borders with Box, or upright hardy Thyme, or some other aromatic herbs or flowers, for the sake of the greater neatness.

And in order to preserve the paths and alleys of compartments firm, even, and durable, they lay them with a coat of sand or gravel, two or three inches

thick, keeping them hoed and weeded as often as there should be occasion.

These compartments were much esteemed by the French, whose gardens were all laid out into several compartments, salons, bosquets, &c. after the manner of architects in buildings; but these stiff, unnatural gardens are now justly exploded, and a much better taste has of late prevailed in the English gardens.

COMPOSTS are so called of *composita*, or *composita*, *Lat.* compounds, or *componere*, *Lat.* to compound or mix: and in husbandry and gardening they signify several sorts of soils or earthy matter mixed together, in order to make a manure for assisting the natural earth in the work of vegetation, by way of amendment or improvement.

Composts are various, and ought to be different, according to the different nature or quality of the soils which they are designed to meliorate: and according as the land is either light, sandy, loose, heavy, clayey, or cloddy. A light loose land requires a compost of a heavy nature, as the scouring of deep ditches, ponds, &c.

So on the other hand, a land that is heavy, clayey, or cloddy, requires a compost of a more sprightly and fiery nature, that will insinuate itself into the lumpish clods; which if they were not thus managed, would very much obstruct the work of vegetation.

The great use of composts is for such plants as are preserved in pots or tubs; or in small beds or borders of flower-gardens; which is what I shall here mention, and shall treat of those composts or dressings, which are used in gardens and fields, under the articles of **DUNG** and **MANURE**.

As some plants delight in a rich light soil, others in a poor sandy soil, and some in a loamy soil; so there should be different composts prepared, in all those gardens, where a great variety of plants are cultivated: and this is much more necessary in countries at a great distance from London, than in the neighbourhood of it, because there is so great variety of lands, within ten miles round London, which have been so long dressed and cultivated, that a supply of earth fit for all sorts of plants, may be easily procured; but in some places which are at a distance from large towns, it is very difficult to procure a quantity of earth proper for the choicer sorts of flowers and plants; therefore the composts will require more care, and should be mixed a considerable time longer before they are used; that they may have the advantage of heat and cold, to meliorate and improve them; and should be frequently turned over, that the parts may be well mixed and incorporated; and the clods well broken and divided.

Almost every one who hath written on this subject, hath directed the procuring of the upper surface of earth from a pasture ground, as one of the principal ingredients, in most composts for plants, which is certainly a very good one, provided it has time to meliorate before it is used; for if this is mixed up hastily, and put into pots or tubs, before it has had a winter's frost, and summer's heat, to loosen the parts effectually; it will unite and cake together, so hard, as to starve the plants that are put into it. For all earth when put into pots or tubs, is much more apt to bind, than when it is in beds; therefore should be in proportion made looser, according to the nature of the plants for which it is designed, than when it is intended for beds or borders. So that if this earth from a pasture, cannot be prepared and mixed at least one year before it is used, it will be much better to take the earth of a kitchen-garden which has been well wrought and dunged; but this should be clear from all roots of trees and bad weeds. If this earth is well mixed with the other composts six months, and often turned over, it will be fitter for pots and tubs, than the other will in twice that time, as I have frequently experienced, so can write from knowledge, not from theory. This earth being the principal ingredient in those composts designed for such plants as require a rich soil, the next is to have a quantity of very rotten

rotten-dung, from old hot-beds; or for those plants which delight in a cool soil, a quantity of rotten neats dung is preferable. The proportion of this must be according to the quality of the earth; for if that is poor, there should be one third part of dung, but if it be rich, a fourth part or less will be sufficient. These, when well incorporated and the parts divided, will require no other mixture, unless the earth is inclinable to bind, in which case it will be proper to add some sand or sea-coal ashes to it; if sea-sand can be easily procured, that is the best, the next to that is drift-sand; but that from pits is by no means proper. The proportion of this must be according to the nature of the earth, for if that is stiff, there must be a greater proportion used, but this should not exceed a fifth part, unless it is very strong, in which case it will require more, and a longer time to lie, and must be often turned over before it is used.

The next compost, which is designed for plants which do not require so good earth, and naturally grow on loose soils, should be half of the before-mentioned earth from a pasture, or that from a kitchen-garden; and if these are inclinable to bind, there should be a third part sand, and the other part rotten tan, which will be of great use to keep the parts divided, and let the moisture pass off.

The composition for most of the succulent plants, is prepared with the following materials; the earth from a common, where it is light, taken on the surface, one half, the other half sea or drift-sand, and old lime-rubbish screened of equal parts; these, well mixed and often turned over, I have found to answer better than any other compost, for most of the very succulent plants.

The other sort of compost, which is designed for plants that delight in a very loose, light, rich earth; should be made of light earth taken from a kitchen-garden, which has been well dunged, and thoroughly wrought, like those near London, one half; of rotten tanners bark one third, and the other part mud from the scouring of ditches, or from the bottoms of ponds, where the soil is fat: but this mud should lie exposed in small heaps a whole year, and often turned over before it is mixed with the other, and afterward frequently turned and mixed, for eight months or a year before it is used.

In all mixtures, where rotten wood may be required, if the rotten tanners bark, which is taken from old hot-beds is used, that will answer every purpose of the other; and wherever sand is necessary in any compost, the sea-sand should always be preferred to all other, as it abounds with more salts; but this should not be used fresh, because the salts should be exposed to the air, which will loosen the particles, and thereby render them better adapted for the nutriment of vegetables.

There are some who have directed the use of rotten leaves of vegetables, as an excellent ingredient in most composts; but from many years experience, I can affirm, they are of little use, and contain the least quantity of vegetable pasture, of any dressing which is used. Others, who never have had any experience in the culture of plants, have directed different composts for almost every plant; and these composts consist of such a variety of ingredients, as greatly to resemble the prescriptions of a quack doctor; for no person who has been conversant in the business of gardening, could be guilty of such gross absurdities: for it is well known, that a few different composts will be sufficient for all the known plants in the world. But those who pretend to give direction for the culture of plants from theory only, begin at the wrong end, for the true knowledge of gardening or agriculture, must be from experience, and is not to be obtained in a garret.

The several sorts of dressing for land, will be particularly treated under their respective titles, and in general they will be mentioned under the article of DUNG and MANURE.

In making of any compost, great care should be had,

that the several parts are properly mixed together, and not to have too much of any one sort thrown together; therefore, when three or four several sorts are to be mixed together, there should be a man or two placed to each sort, in proportion to the quantity of each; for if two parts of any one sort are requisite to be added, there should be two men put to that, and but one to each of the other: and these men must be careful to spread each sort in such a manner over each other, as that they may be exactly mixed together. Another thing which should be observed is, never to lay these composts in too large heaps, but rather continue them in length, laying them up in a ridge, so that the sun and air may more easily penetrate through it: and, as these composts should (if possible) be made a year before they are used, that they may enjoy a summer's sun, and winter's frost, they should be frequently turned over, which will prevent the growth of weeds, and expose every part of the heaps equally to the sun and air, which is of great advantage to all sorts of composts; for the more they are exposed to the influences of these, the better will the earth be prepared for vegetation, which is evinced by the fallowing of land, which, when rightly managed, is equivalent to a dressing.

COMPOUND FLOWERS are such as consist of many florets, or semiflorets, or both together, which are included in one common empalement, so make up what is commonly called one whole flower.

CONE. A cone is a hard, dry, seed-vessel of a conical figure, consisting of several woody parts; and is, for the most part scaly, adhering closely together, and separating when ripe.

CONIFEROUS-TREES are such as bear cones; as, the Cedar of Lebanon, Fir, Pine, &c.

CONIUM. Lin. Gen. Plant. 299. Cicuta. Tourn. Inst. R. H. 306. tab. 160. Hemlock.

The **CHARACTERS** are,

It is an umbelliferous plant; the general umbel is composed of several small ones termed rays, which spread open, the rays or small umbels are also spread in the like manner. Both these have involucrems, composed of many short leaves. The petals of the greater umbel are uniform; each flower is composed of five unequal heart-shaped petals, which turn inward; they have five stamina, which are terminated by roundish summits. The germen, which is situated under the flower, supports two reflexed styles, crowned by obtuse stigmas. The germen afterward becomes a roundish channelled fruit, divided into two parts, containing two seeds, which are convex and furrowed on one side, and plain on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flowers having five stamina and two styles.

The **SPECIES** are,

1. **CONIUM** (*Maculatum*) seminibus striatis. Hort. Cliff. 92. *Conium with striated seeds.* Cicuta major. C. B. P. 160. *Greater Hemlock.*
2. **CONIUM** (*Tenuifolium*) seminibus striatis, foliolis tenuioribus. *Conium with striated seeds and narrower leaves.* Cicuta major, foliis tenuioribus. C. B. P. 160. *Greater Hemlock with narrower leaves.*
3. **CONIUM** (*Africanum*) seminibus aculeatis. Hort. Cliff. 92. *Hemlock with prickly seeds.* *Caucalis Africana*, folio minore, Rutæ. Boerh. Ind. alt. Sp. 63.

The first sort grows naturally on the side of banks and roads in many parts of England; this is a biennial plant, which perishes after it hath ripened seeds. It hath a long taper root like a Parsnep, but much smaller. The stalk is smooth, spotted with purple, and rises from four, to upwards of six feet high, branching out toward the top into several smaller stalks, garnished with decomposed leaves, whose lobes are cut at the top into three parts; these are of a lucid green, and have a disagreeable smell. The stalks are terminated by umbels of white flowers, each being composed of about ten rays (or small umbels) and have a great number of flowers, which spread open, each sitting upon a distinct foot-stalk; the seeds are small and channelled, and like those of Aniseed.

Aniseed. It flowers in June, and the seeds ripen in autumn.

The second sort differs from the first, in having taller stalks, which are not so much spotted. The leaves are much narrower, and of a paler green; and this difference is constant, for I have cultivated it near twenty years in the Chelsea garden, where it has not varied. The seeds were sent me from Germany, where it grows naturally. This is biennial as the former.

The third sort grows naturally near the Cape of Good Hope, in Africa, from whence the seeds were brought to Holland, where the plants have been preserved in some of their curious gardens of plants. The seeds of this plant were sent me by the late Dr. Boerhaave, professor of Botany at Leyden. This plant rarely grows more than nine inches high; the lower leaves are divided somewhat like those of the small wild Rue, and are of a grayish colour; those upon the stalk are much narrower, but of the same colour; these are terminated by umbels of white flowers, each of the larger umbels being composed of three small ones; the involucre hath three narrow leaves, situated under the umbel. This flowers in July, and ripens seed in autumn, soon after which the plants decay.

The first sort grows wild in most parts of England, so is seldom allowed room in gardens, because it is supposed to have a poisonous quality; some physicians have affirmed that it is so to all animals, while others have assured us, that it is eaten by the inhabitants of some parts of Italy when it is young, and is by them esteemed a great dainty. Mr. Ray mentions that he has found the gizzard of a thrush, full of Hemlock seeds, with four or five grains of Corn, intermixed with it, which, in the time of harvest, that bird had neglected for Hemlock, so very fond was it of that seed which we reckon pernicious. However, it is very certain, that scarce any animal will eat the green herb; for it is very common to see the grass, and most other weeds eat close where cattle are allowed to feed, and all the plants of Hemlock, which were growing left untouched.

This plant is esteemed by many physicians, as an excellent remedy to dissolve schirrous tumors; and some have greatly recommended it for cancers, and most of them agree, that it may be prescribed as a good narcotic.

The second sort is preserved in some botanic gardens for the sake of variety. If the seeds of this are permitted to scatter, the plants will come up in plenty, so if they are not rooted out, will become as troublesome weeds as the first sort.

The third sort is an humble plant, and being tender, will never become troublesome; for unless the winters are very favourable, this plant will not live in the open air in England. The seeds of this sort should be sown in pots in autumn soon after they are ripe, and placed under a common frame in winter, where they may be exposed to the open air at all times when the weather is mild, and only covered in bad weather. The plants will come up very early in the spring, and must then be exposed to the open air constantly when the weather will permit, otherwise they will draw up very weak. As these plants do not bear transplanting well, they should be thinned, and not more than four or five left in each pot; and as the plants have no great beauty, a few of them will be sufficient to continue the sort, where a variety of plants are preserved. The other culture is only to keep them clean from weeds, and in very dry weather to water them.

There is another species of this genus according to most of the botanists, which is now separated from it, and placed singly, under the title of *Æthusa*. This was titled, *Cicuta minor petroselinio similis*, by Caspar Bauhin, i. e. *Smaller Hemlock with the appearance of Parsley*. This is a weed which frequently is found in gardens, especially in rich ground, and is generally supposed to be very poisonous: some persons who have ignorantly gathered this herb, and used it for Parsley, having been poisoned by it. Therefore

it was formerly called Fools Parsley. This may be distinguished from Parsley, by the narrowness of the small leaves, which are also more pointed, and of a darker green. But those who are afraid of being deceived in this, should always use the curled Parsley, which is so different from this, that it cannot be mistaken for it.

CONNARUS. Zeylon Sumach.

The CHARACTERS are,

It hath a woolly erect empalement of one leaf, cut into five segments, which is permanent, and five spear-shaped erect petals which are equal; it has ten awl-shaped stamina, which are joined at their base, and are alternately long and short, terminated by roundish summits, and a round germen supporting a cylindrical style, crowned by an obtuse stigma; the empalement afterward becomes an oblong gibbous capsule opening with two valves, having one cell, inclosing one large oval seed.

This genus of plants is ranged in the second order of Linnæus's sixteenth class, intitled Monodelphia Decandria, the flower having ten stamina, which are joined in one house.

We know but one SPECIES of this genus, viz.

CONNARUS (*Monocarpus*). Flor. Zeyl. 248. *One seeded Connarus*. Rhus Zeylanicus trifolius, phascoli facie, floribus copiosis spicatis. Burn. Zeyl. 199. tab. 89.

This plant grows naturally in India; it rises with a ligneous stalk eight or ten feet high, which is hard, rigid, and covered with a black bark, and divides upward into two or three branches, garnished with trifoliate leaves, having long foot-stalks placed alternate; the lobes are oval, smooth, and entire, each having a short petiolus fastened to the foot-stalk; these remain green the whole year: the flowers are produced in large panicles at the extremity of the branches, they are small, hairy, and of a greenish yellow colour, but are rarely succeeded by seeds in Europe.

This plant is usually propagated in the gardens by laying down the young branches, which, if tongued, (in the manner practised for Carnations) and duly watered, will put out roots in twelve months, when they may be cut off from the old plants, and each planted in a separate small pot, filled with fresh light earth, plunging them into a moderate hot-bed, to forward their taking new root, observing to shade them from the sun every day, and to water them as they may require it: after this the plants should be treated in the same way as other exotic plants which are not too tender, placing them in a dry stove in winter, and for about three months in the summer they may be removed into the open air, in a warm sheltered situation.

The cuttings of this plant will sometimes take root, if they are planted in pots, plunged into a moderate hot-bed of tanners bark, and closely covered with hand-glasses, or small bell-glasses; but unless they are carefully managed they seldom succeed.

If fresh seeds can be procured from abroad, they should be sown in small pots, plunged into a moderate hot-bed, and when the plants are fit to remove they should be separated, planting each into a separate pot, and plunged into a moderate hot-bed, treating them in the manner as the layers.

CONOCARPODENDRON. See PROTEA.

CONOCARPUS. Lin. Gen. Plant. 236. Rudbeckia. Houst. Nov. Gen. 21. Button-tree, vulgò.

The CHARACTERS are,

The flowers are collected in a globular head, each standing in a scaly empalement. At the bottom is situated a large compressed germen, crowned by the empalement of the flower, which is small, sharp-pointed, and divided into five parts at the top. The flower hath five petals; it hath five, or sometimes ten slender stamina, which extend beyond the petals, terminated by globular summits. The germen is large, compressed, and obtuse, supporting a single style which is longer than the stamina, and is crowned by an obtuse stigma. The germen afterward becomes a single seed, inclosed in the scale of the fruit, which is shaped like the cone of Alder.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, from the flower having five stamina and one style.

The SPECIES are,

1. CONOCARPUS (*Erecta*) foliis lanceolatis erecta. Lin. Sp. 250. Upright Conocarpus with spear-shaped leaves. Rudbeckia erecta longifolia. Houst. MSS. Commonly called Button-tree in the West-Indies.
2. CONOCARPUS (*Procumbens*) frutescens, procumbens, foliis ovatis, crassis, floribus alaribus & terminalibus. Shrubby trailing Conocarpus with oval thick leaves, and flowers growing on the sides, at the ends of the branches. Rudbeckia maritima procumbens rotundifolia. Houst. MSS. Maritime trailing Rudbeckia, with a round leaf.

The first sort grows plentifully in most of the sandy bays, in all the islands of the West-Indies. It rises with a woody upright stem about sixteen feet high, sending out many side branches, which also grow erect; these are garnished with spear-shaped leaves, having broad short foot-stalks, and are placed alternate on every side the branches. The flowers grow upon short branches, which arise from the wings of the leaves; these have three or four small leaves on their lower part, under the flowers; each of these branches are terminated by six or eight conical heads of flowers, which have some resemblance to those of Acacia, but each of these come out of a scaly covering; the flowers are small, of a reddish colour, having five slender stamina, and one style, which stand out farther than the petal. The flowers are succeeded by single seeds, which are included in the scales of the conical fruit.

The second sort hath short crooked branches, which divide and spread out on every side upon the ground; these are covered with a grayish bark, and their upper parts are garnished with oval thick leaves, a little larger than those of the Dwarf Box; they have very short foot-stalks, and are placed on every side the branches without order. The flowers are collected in small round heads, which come out single from the side of the branches, and in loose spikes at the end; these are small, and of an herbaceous colour; the scales are rough, and the cones are of a looser texture than those of the former sort.

This was discovered by the late Dr. William Houstoun, growing plentifully in the marshy grounds near the sea, at the Havannah, from whence he sent the seeds to England, in 1730.

Both these sorts are preserved in some curious gardens for the sake of variety, but they are plants of no great beauty: they are propagated from seeds, which must be obtained from the places of their natural growth, for they never produce any good seeds in Europe: these seeds, if they are fresh, will come up very soon, if they are sown upon a good hot-bed; and if the plants are potted, and preserved in the bark-stove, they will make great progress; but they are too tender to live in this country, unless they are constantly kept in the stove, and treated in the same manner with other exotic plants; observing, as they are natives of swamps, to supply them often with water; but in winter they must have it very sparingly. The plants are Evergreen, casting off their old leaves when the new come out.

- CONSOLIDA MAJOR. See SYMPHYTUM.
 CONSOLIDA MEDIA. See BUGULA.
 CONSOLIDA MINIMA. See BELLIS.
 CONSOLIDA REGALIS. See DELPHINIUM.
 CONVALLARIA. Lin. Gen. Plant. 383. Lilium Convallium. Tourn. Inst. R. H. 77. tab. 14. Lily of the valley. To this genus Dr. Linnæus has joined the Polygonatum of Tournefort, or Solomon's Seal.

The CHARACTERS are,

The flower hath one petal, which is bell-shaped, and divided at the brim into six obtuse segments which spread open and are reflexed. It hath no empalement. It hath six stamina, which are inserted into the petal, but are shorter, terminated by oblong summits, which are erect. In the

center is situated a globular germen, supporting a slender style, which is longer than the stamina, crowned by a three cornered obtuse stigma. The germen afterward becomes a globular berry, with three cells, containing one roundish seed.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. CONVALLARIA (*Majalis*) scapo nudo. Flor. Lapp. 113. Convallaria with a naked stalk. Lilium convallium album. C. B. P. 304. White Lily of the Valley. There is a variety of this with reddish flowers, which is preserved in gardens, titled by Caspar Bauhin Lilium Convallium flore rubente. Pin. 304.
2. CONVALLARIA (*Latifolia*) scapo nudo, foliis latioribus. Convallaria with a naked stalk and broader leaves. Lilium Convallium latifolium. C. B. P. 136. Broad-leaved Lily of the Valley. There is also a variety of this with double variegated flowers which is preserved in gardens. This Tournefort titles Lilium Convallium latifolium, flore pleno variegato. Inst. R. H. 77. Broad-leaved Lily of the Valley, with a large variegated flower.
3. CONVALLARIA (*Multiflora*) foliis alternis, amplexicaulibus caule tereti axillaribus pedunculis multifloris. Convallaria with leaves placed alternate, embracing the taper stalk, whose foot-stalks have many flowers. Polygonatum latifolium vulgare. C. B. P. 305. Common broad-leaved Solomon's Seal.
4. CONVALLARIA (*Odorata*) foliis alternis, semiamplexicaulibus, floribus majoribus axillaribus. Convallaria with alternate leaves which half embrace the stalks, and larger sweet-scented flowers. Polygonatum latifolium, flore majore odore. C. B. P. 303.
5. CONVALLARIA (*Polygonatum*) foliis alternis amplexicaulibus, caule anapty, pedunculis axillaribus subunifloris. Lin. Mat. Med. 168. Convallaria with alternate leaves embracing the stalks, and foot-stalks having one flower. Polygonatum floribus ex singula tribus pedunculis. C. B. 3. p. 530. Common Solomon's Seal.
6. CONVALLARIA (*Stellata*) foliis amplexicaulibus plurimis. Lin. Sp. 452. Convallaria with many leaves embracing the stalks. Polygonatum Canadense spicatum fertile. Cornut. Canad. 33.
7. CONVALLARIA (*Verticillata*) foliis verticillatis. Flor. Lapp. 114. Convallaria with leaves growing in whorls. Polygonatum angustifolium, non ramosum. C. B. P. 303.
8. CONVALLARIA (*Racemosa*) foliis sessilibus, racemo terminali composito. Lin. Sp. Plant. 452. Convallaria with leaves sitting close to the stalks, which are terminated by compound spikes of flowers. Polygonatum Virginianum erectum, spicatum, flore stellato sterili. Mor. Hist. 3. 537.
9. CONVALLARIA (*Bifolia*) foliis cordatis. Flor. Lapp. 113. Convallaria with heart-shaped leaves. This is the Smilax unifolio humillima. Tourn. Inst. App. 564. Lowest Smilax with a single leaf; and the Lilium Convallium minus. C. B. P. 304. The least Lily of the Valley.

The first sort grows naturally in great plenty in the woods near Woburn, in Bedfordshire, from whence the markets in London are generally supplied with the flowers. It is also cultivated in gardens for the sweetness of the flowers, and formerly it grew in great plenty on Hampstead-heath, but of late years it has been seldom found there; for since all the trees have been destroyed, the plants have not flowered there as formerly, nor have the roots increased.

This hath a slender fibrous root, which creeps under the surface of the ground, and thereby propagates in great plenty. The leaves come up by pairs; their foot-stalks, which are about three inches long, are wrapped together in one cover, and at the top divide into two parts, each sustaining a single leaf, one of which rises a little above the other; these leaves are from four to five inches long, and near an inch and a half broad in the middle, lessening gradually to both ends; they have many longitudinal veins, running parallel

CON

parallel to the midrib, which is not situated exactly in the middle, but diverges to one side; the foot-stalks of the flowers arise immediately from the root, on one side the leaves; these are naked, about five inches long, adorned toward their upper parts with pendulous white flowers, ranged on one side the stalk, which decline to one side; each flower stands upon a short separate foot-stalk, which are bending and crooked. The flowers are of the short bell-shaped kind, their brims being reflexed, which are slightly cut into six parts; they have six stamina, which are inserted in the petal of the flower, and are shorter than the tube, and a single style arising from the germen, which is triangular, crowned by a three-cornered stigma; the germen afterward becomes a globular berry, of a red colour when ripe, inclosing three roundish seeds. It flowers in May, from whence it has been titled May Lily. The seeds ripen in autumn. The flowers of this sort are used in medicine; they are esteemed cephalic and cordial, so are recommended for palsies, epilepsies, and spasms; there is prepared a conserve, and a compound distilled water of the flowers. This compound water is by the Germans titled *aqua aurea*, or *golden water*, because of its excellent virtues.

There is another variety of this mentioned with narrow leaves, which I suppose may arise from the soil, or situation, for the roots which I have taken up in places where they have naturally narrow leaves, when planted in the garden, have produced leaves as broad as the common sort; but the sort with red flowers has constantly continued the same above forty years, without any variation. The flowers of this are smaller, the stalks are redder, and the leaves of a darker green than those of the common sort; but as I have not propagated this sort by seeds, I cannot be sure if it is a distinct species, or only a seminal variety.

The second sort I received from the Alps, where it naturally grows; this has retained its difference in the garden, where it grew in the same soil and situation with the common sort, so I make no doubt of its being a distinct species. The other with a double variegated flower is supposed to be only a variety of this, therefore I have not enumerated it as a different sort, but the flowers are much larger, and beautifully variegated with purple and white. I received a plant of this sort from the royal garden at Paris, which has flowered several years in the Chelsea garden, but the roots do not increase so much as the common sort.

These plants require a loose sandy soil, and a shady situation; they are propagated by parting of their roots, which multiply in great plenty. The best time to transplant and part the roots, is in autumn. They should be planted near a foot asunder, that their roots may have room to spread, for if they agree with the soil and situation, they will meet and fill the ground in one year. If these roots are planted in a rich soil, they will spread and multiply greatly, but will not be so productive of flowers.

The only culture which these plants require, is to keep them clean from weeds, and to transplant and separate the roots every third or fourth year, otherwise they will be so greatly matted together, as not to have proper nourishment, so the flowers will be small, and few in number.

The third sort is a native of the Alps and Appennines; the stalks of this (when growing in good ground) generally rise three feet high; they are taper, and garnished with oblong oval leaves placed alternate, embracing the stalks with their base; they have several longitudinal veins, resembling the leaves of white Hellebore: the foot-stalks of the flowers are produced from the wings of the leaves, which support four or five flowers on each; these flowers are larger than those of the common sort, but their tubes are more contracted, and are succeeded by pretty large berries, which when ripe turn of a bluish colour; it flowers in May and June, and the seeds ripen in autumn.

The fourth sort is the broad-leaved Solomon's Seal,

CON

which is said to grow naturally in England, but I doubt ours is different from that mentioned by Catpar Bauhin under that title; for in two places where I have found it growing, the stalks were much shorter, the leaves were broader, and their borders turned inward, and this difference continues in the garden where it grows in the same soil and situation with the common sort.

The fifth sort is the common Solomon's Seal; this hath a fleshy white root, as large as a man's finger, which multiplies in the ground, and is full of knots, from whence it had the name of *Polygonatum*, or many knees. In the spring arise several taper stalks, which grow near two feet high, adorned with oblong oval leaves, placed alternate, having many longitudinal veins running parallel to the middle, and embrace the stalk with their base; these are ranged on one side of the stalk, and on the opposite side come out the foot-stalks of the flowers, which are about an inch long, dividing at the top into three or four smaller, each sustaining a single tubulous flower, cut into six parts at the brim, where it is green, the lower part of the tube being white; they have each six slender stamina, surrounding a single style, which arises from the germen, and is crowned by a blunt stigma; the germen afterward becomes a round berry, about the size of Ivy berries, each inclosing three seeds. This flowers in May, and the seeds ripen in autumn, and then the stalks decay.

The sixth sort rises with an upright stalk about two feet high, garnished with long narrow leaves, which stand in whorls round the stalk; there are generally five of these placed at each joint, which are four inches long, and half an inch broad, smooth, and of a light green. The flowers come out from the same joints, standing upon short foot-stalks, each supporting five or six flowers, which are smaller, and have much shorter tubes than either of the former sorts; they are of a dirty white, tipped with green, and slightly cut into six parts at the top. It grows naturally in the northern parts of Europe.

The seventh sort grows naturally in most parts of North America; I have received plants of this from New England, Philadelphia, and several other places. This rises with an upright stalk near two feet high, garnished with oblong leaves, ending in sharp points; they are near five inches long, and two and a half broad, having three large longitudinal veins, with several smaller between, which join at both ends. The leaves are alternate, standing close to the stalks, and are of a light green on their upper side, but are paler on their under. The flowers are produced in branching spikes at the extremity of the stalks, each being composed of several small loose spikes of star-like flowers, of a pale yellow, which fall away without producing any seed. This flowers the latter end of May, or the beginning of June, and the stalks decay in autumn; but the root is perennial, and propagates by offsets.

The eighth sort is a native of the same countries as the last mentioned; this sends up stalks two feet high, garnished with many oblong leaves embracing the stalks with their base. The flowers are produced in single spikes at the top of the stalks, which are in shape and colour like those of the seventh; but these are succeeded by small red berries, about the size of those of the Lily of the Valley. This sort flowers the beginning of June, and the berries ripen in autumn.

All the sorts of Solomon's Seal are very hardy plants; they delight in a light soil and a shady situation, so are very proper to plant in wilderness quarters under tall trees, where if they are not crowded by lower shrubs, they will thrive and multiply exceedingly, and during the summer season will make an agreeable variety, the whole appearance of the plants being very singular.

They all multiply very fast by their creeping roots, especially when they are planted in a proper soil and situation. The best time to transplant and part the roots

roots is in autumn, soon after their stalks decay; those which are removed at that season, will grow much stronger than those which are planted in the spring, which is the reason of my preferring that season; but they may be safely transplanted any time after the stalks decay, till the roots begin to shoot in the spring. As these roots greatly increase, they should be planted at a wide distance from each other, that they may have room to spread; for they should not be removed oftener than every third or fourth year, where they are expected to grow strong, and produce a good number of stalks, in which their beauty consists. The only culture these plants require, is to dig the ground between them every spring, and keep them clean from weeds.

The roots of the fifth sort are used in medicine, and are greatly recommended for their efficacy in all manner of contusions. The distilled water of the plant clears the face and beautifies the complexion: a decoction of it cures the itch, and such like cutaneous distempers.

CONVOLVULUS. Lin. Gen. Plant. 198. Tourn. Inst. R. H. 82. tab. 77. Bindweed. It is so titled from convolvendo, Lat. rolling round, or twining about.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is divided into five parts at the top; the flower hath one large bell-shaped petal, which spreads open. It hath five short stamina, terminated by oval compressed summits, and a roundish germin, supporting a slender style, crowned by two broad oblong stigmas. The empalement afterward becomes a roundish capsule, with one, two, or three valves, containing several seeds which are convex on their outside, but on the inside angular.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. **CONVOLVULUS (Arvensis)** foliis sagittatis utrinque acutis, pedunculis unifloris. Flor. Suec. 173. Bindweed with arrow-shaped leaves pointed on both sides, and a single flower on each foot-stalk. Convolvulus minor arvensis. C. B. P. 294. Smaller Field Bindweed, commonly called Gravel Bindweed.
2. **CONVOLVULUS (Sepium)** foliis sagittatis posticè truncatis, pedunculis tetragonis unifloris. Prod. Leyd. 427. Bindweed with arrow-shaped leaves, which are torn behind, and a single flower on each foot-stalk. Convolvulus major albus. C. B. P. Larger white Bindweed, called Bearbind.
3. **CONVOLVULUS (Scammonia)** foliis sagittatis posticè truncatis, pedunculis teretibus subtrifloris. Prod. Leyd. 427. Bindweed with arrow-shaped leaves torn behind, and two flowers on each foot-stalk. Convolvulus Syriacus & Scammonia Syriaca. Mor. Hist. 2. p. 12. Syrian Bindweed and Syrian Scammony.
4. **CONVOLVULUS (Purpureus)** foliis cordatis indivisis fructibus cernuis pedicellis incrassatis. Lin. Sp. 219. Bindweed with heart-shaped undivided leaves, nodding fruit, and swelling foot-stalks. Convolvulus purpureus, folio subrotundo. C. B. P. 295. Purple Bindweed with a roundish leaf, commonly called Convolvulus major, or Greater Bindweed.
5. **CONVOLVULUS (Indicus)** foliis cordatis, acuminatis, pedunculis trifloris. Bindweed with heart-shaped pointed leaves, and three flowers on each foot-stalk. Convolvulus major, folio subrotundo, flore amplo purpureo. Sloan. Cat. Jam. 55. Greater Bindweed with a roundish leaf, and a large purple flower.
6. **CONVOLVULUS (Nil)** foliis cordatis trilobis villosis, calycibus lævibus, capsulis hirsutis, pedunculis bifloris. Bindweed with heart-shaped leaves, having three lobes, which are hairy, smooth flower-cups, hairy seed-vessels, and two flowers on each foot-stalk. Convolvulus cæruleus hederaceo anguloso folio. C. B. P. 295. Blue Bindweed with an angular Ivy leaf.
7. **CONVOLVULUS (Batatas)** foliis cordatis hastatis quinquenerviis, caule repente hispido tubifero. Lin. Sp. Plant. 154. Bindweed with spear heart-shaped leaves,

five nerves, and a creeping stinging stalk bearing tubers. Convolvulus radice tuberosa esculensâ minore purpurea. Sloan. Cat. Jam. 54. Bindweed with a small, purple, tuberous, esculent root, commonly called Spanish Potatoes.

8. **CONVOLVULUS (Palmatis)** foliis palmatis, lobis septem-sinuatis acutis, pedunculis unifloris, calycibus maximis patentibus. Bindweed with palmated leaves, with seven sinuated pointed lobes, a single flower on each foot-stalk, and a large spreading empalement. Convolvulus pentaphyllos, folio glabro dentato, viticulis hirsutis. Plum. Cat.
9. **CONVOLVULUS (Aristolochifolius)** folio hastato lanceotatis, auriculis rotundatis, pedunculis multifloris. Bindweed with spear-pointed leaves, having rounded ears, and many flowers on each foot-stalk. Convolvulus Americanus, Aristolochiæ folio longiore, floribus plurimis ex uno pediculo insidentibus. Houst. MSS.
10. **CONVOLVULUS (Hirtus)** foliis cordatis subhastatisque villosis, caule petiolisque pilosis, pedunculis multifloris. Lin. Sp. Plant. 159. Bindweed with heart-shaped leaves, somewhat spear-pointed and downy, with hairy stalks and foot-stalks, having many flowers. Convolvulus Americanus Polyanthos, Althææ folio villoso. Houst. MSS.
11. **CONVOLVULUS (Glabrus)** foliis ovato oblongis, glabris pedunculis unifloris, calycibus decempartitis. Bindweed with oval, oblong, smooth leaves, and foot-stalks having a single flower, whose empalement is cut into ten parts. Convolvulus foliis oblongis, glabris floribus amplis purpureis. Houst. MSS.
12. **CONVOLVULUS (Pentaphyllos)** hirsutissimus, foliis quinquelobatis, pedunculis longissimis bifloris. Very hairy Bindweed, with leaves having five lobes, and very long foot-stalks, with two flowers. Convolvulus pentaphyllos hirsutis. Plum. Cat.
13. **CONVOLVULUS (Frutescens)** caule fruticoso, glabro, foliis quinque lobis, pedunculis geniculatis unifloris, capsulis maximis. Bindweed with a shrubby smooth stalk, leaves having five lobes, many jointed foot-stalks with one flower, and very large seed-vessels. Convolvulus pentaphyllos, flore & fructu purpureis maximis. Plum. Cat.
14. **CONVOLVULUS (Brasilensis)** foliis emarginatis, basi biglandulosis, pedunculis trifloris. Lin. Sp. Plant. 159. Bindweed with indented leaves, having two glands and foot-stalks, with three flowers. Convolvulus marinus Catharticus, folio rotundo, flore purpureo. Plum. Pl. Amer. 89. tab. 104.
15. **CONVOLVULUS (Multiflorus)** foliis cordatis, glabris, pedunculis multifloris, femine villoso ferrugineo. Bindweed with smooth heart-shaped leaves, foot-stalks having many flowers, and seeds covered with an iron-coloured down. Convolvulus Americanus vulgaris folio, capsulis triquetris numerosis, ex uno puncto, longis petiolis propendentibus, femine lanugine ferrugineâ villosa. Pluk. Phyt. tab. 167. f. 1.
16. **CONVOLVULUS (Canariensis)** foliis cordatis pubescentibus, caule perenni, villoso, pedunculis multifloris. Lin. Sp. Plant. 155. Bindweed with soft, woolly, heart-shaped leaves, a hairy perennial stalk, and foot-stalks having many flowers. Convolvulus Canariensis sempervirens, foliis mollibus & incanis. Hort. Amst. 2. p. 101.
17. **CONVOLVULUS (Hederaceus)** foliis triangularibus acutis, floribus plurimis sessilibus patulis, calycibus acutis multifidis. Bindweed with sharp-pointed triangular leaves, many spreading flowers set close to the stalk, and acute empalements ending in many points. Convolvulus folio hederaceo, anguloso, lanuginoso, flore magno, cæruleo, patulo. Sloan. Cat. Jam. 56.
18. **CONVOLVULUS (Roseus)** foliis cordatis, acuminatis pedunculis bifloris. Bindweed with heart-shaped pointed leaves, and foot-stalks having two flowers. Convolvulus Americanus hirsutus, folio acuminato, flore amplo roseo. Houst. MSS.
19. **CONVOLVULUS (Repens)** foliis sagittatis posticè obtusis, caule repente, pedunculis unifloris. Lin. Sp. Plant. 158. Bindweed with narrow-pointed leaves, which are obtuse at the foot-stalk, a creeping stalk, and one flower

- flower on each foot-stalk. *Convolvulus marinus catharticus*, foliis Acetosæ, flore niveo. Plum. Pl. Am. 89. tab. 105.
20. *CONVOLVULUS (Betonifolius)* foliis cordato sagittatis, pedunculis unifloris. *Bindweed with heart-shaped arrow-pointed leaves, and foot-stalks having a single flower.* *Convolvulus exoticus*, *Betonicæ folio*, flore magno albo fundo purpureo. Cat. Hort. R. Par.
21. *CONVOLVULUS (Siculus)* foliis cordato ovatis, pedunculis unifloris, bracteis lanceolatis, flore sessile. Hort. Cliff. 68. *Bindweed with oval heart-shaped leaves, foot-stalks having one flower, spear-shaped bractes, and the flower sitting close to the stalk.* *Convolvulus siculus minor*, flore parvo auriculato. Bocc. Pl. Sic. 89.
22. *CONVOLVULUS (Elegantissimus)* foliis palmatis sericeis, pedunculis bifloris, calycibus acutis. *Bindweed with silky palmated leaves, foot-stalks having two flowers, and sharp-pointed empalements.* *Convolvulus argentibus*, *elegantissimus*, foliis tenuiter incis. Tourn. Inst. R. H. 85.
23. *CONVOLVULUS (Altheoides)* foliis cordatis incis. & incanis, pedunculis bifloris, calycibus obtusis. *Bindweed with hoary heart-shaped leaves, which are jagged, foot-stalks having two flowers, and obtuse empalements.* *Convolvulus argenteus folio althææ*. C. B. P. 295.
24. *CONVOLVULUS (Tricolor)* foliis lanceolato-ovatis glabris, caule declinato, floribus solitariis. Vir. Cliff. 68. *Bindweed with oval spear-shaped leaves, a declining stalk, with one flower on each foot-stalk.* *Convolvulus Lusitanicus* flore Cyaneo Brofs; commonly called *Convolvulus minor*.
25. *CONVOLVULUS (Cantabrica)* foliis linearibus acutis caule ramoso subdichotomo, calycibus pilosis. Lin. Sp. 225. *Bindweed with narrow spear-shaped leaves, a branching stalk, and hairy empalements.* *Convolvulus linariæ folio affurgens*. Tourn. Inst. R. H. 83.
26. *CONVOLVULUS (Lineatus)* foliis lanceolatis, sericeis, lineatis petiolatis pedunculis bifloris, calycibus fereceis subfoliaceis. Lin. Sp. 224. *Bindweed with silky spear-shaped leaves, having foot-stalks, with two flowers on each foot-stalk, having silky empalements.* *Convolvulus minor*, *argenteus*, *repens*, *acaulis ferme*. H. R. Par.
27. *CONVOLVULUS (Cneorum)* foliis lanceolatis tomentosis, floribus capitatis, calycibus hirsutis caule erecti-uscule. Lin. Sp. 224. *Bindweed with spear-shaped woolly leaves, foot-stalks and flowers growing in heads, terminating the stalks, which are erect.* *Convolvulus argenteus umbellatus*, *erectis*. Tourn. Inst. R. H. 84.
28. *CONVOLVULUS (Linarifolius)* foliis lineari lanceolatis, acutis caule ramoso, recto, pedunculis unifloris. Hort. Cliff. 68. *Bindweed with narrow spear-shaped leaves, which are pointed, upright branching stalks, and foot-stalks with one flower.* *Convolvulus ramosus incanus*, foliis pilosellæ. C. B. P. 295.
29. *CONVOLVULUS (Soldanella)* foliis reniformibus, pedunculis unifloris. Hort. Cliff. 67. *Bindweed with kidney-shaped leaves, and one flower on each foot-stalk.* *Soldanella maritima minor*. C. B. P. 295. *Lesser Sea Bindweed.*
30. *CONVOLVULUS (Turpethum)* foliis cordatis, angulatis, caule membranaceo, quadrangulati, pedunculis multifloris. Flor. Zeyl. 72. *Bindweed with angular heart-shaped leaves, a quadrangular membranaceous stalk, and foot-stalks having many flowers.* *Convolvulus Zeylanicus*, *alatus*, *maximis*, foliis liliis nonnihil similibus angulosis. Herm. Lud. 177. tab. 178. *Turbith of the shops.*
31. *CONVOLVULUS (Falapa)* foliis variis, pedunculis unifloris, radice tuberosa. *Bindweed with variable leaves, foot-stalks with single flowers, and a tuberous root.* *Convolvulus radice tuberosa Cathartica*. Houst. MSS. *The true Falap.*
- The first sort is very common upon dry banks, and in gravelly grounds, in most parts of England, and is generally a sign of gravel lying under the surface. The roots of this shoot very deep into the ground, from whence some country people call it Devils Guts.
- From the root arises many weak stalks, which trail

on the ground, and fasten themselves about the neighbouring plants; these are garnished with triangular arrow-pointed leaves. The flowers are produced from the side of the branches, having long foot-stalks, each sustaining a single flower, which is sometimes white, at other times red, and frequently is variegated. This is a troublesome weed in gardens, so should be constantly rooted out.

The second sort is also a troublesome weed in gardens, when the roots are intermixed with those of trees and shrubs, or under hedges, where the plants cannot be easily destroyed; but in an open clear spot of ground, where the plants are carefully hoed down for three or four months, they may be effectually destroyed; for when the stalks are broken or cut, a milky juice flows out, and thereby the roots are soon exhausted and decay. The roots of this sort are pretty thick, extend far on every side, and are white. The stalks rise ten or twelve feet high, twining themselves about trees or hedges, and are garnished with large arrow-pointed leaves, which are torn at their base. The flowers come out from the side of the branches upon long foot-stalks, each sustaining one large white flower, which are succeeded by roundish seed-vessels, having three cells filled with seeds, which are convex on one side and plain on the other. It flowers in June, and the seeds ripen in autumn, soon after which the stalks decay to the root; but as every small piece of the root will grow, it renders this a troublesome weed to destroy.

The third sort grows naturally in Syria, where the roots of the plants are wounded, and shells placed under the wounds to receive the milky juice which flows out, which is inspissated, and afterward put up and exported: this is what is called Scammony in the shops; it is a very hardy plant, and will thrive very well in the open air in England, provided it is on a dry soil. The roots of this are thick, run deep into the ground, and are covered with a dark bark. The branches extend themselves on every side to the distance of four or five feet; these are slender, and trail on the ground, if they are not supported, and are garnished with narrow arrow-pointed leaves. The flowers are of a pale yellow, and come out from the side of the branches, two sitting upon each long foot-stalk; these are succeeded by roundish seed-vessels, having three cells, filled with seeds shaped like those of the former sort, but smaller. It flowers in June and July, and the seeds ripen in autumn. If the seeds of this sort are sown in the spring, on a border of light earth, the plants will come up, and require no other culture but to keep them clean from weeds, and thin the plants where they grow too close; for as the branches extend pretty far, the plants should not be nearer than three feet asunder. The stalks decay in autumn, but the roots will abide many years.

The fourth sort is an annual plant, which grows naturally in Asia and America, but has been long cultivated for ornament in the English gardens, and is generally known by the title of *Convolvulus major*. Of this there are three or four lasting varieties; the most common hath a purple flower; but there is one with a white, another with a red, and one with a whitish blue flower, which hath white seeds. All these varieties I have cultivated many years, without observing either of them change. If the seeds of these sorts are sown in the spring, upon a warm border where the plants are designed to remain, they will require no other culture but to keep them clean from weeds; and place some tall stakes down by them, for their stalks to twine about, otherwise they will spread on the ground, and make a bad appearance. These plants, if they are properly supported, will rise ten or twelve feet high; they flower in June, July, and August, and will continue till the frost kills them. Their seeds ripen in autumn.

The fifth sort grows naturally in Jamaica, from whence the late Dr. Houstoun sent me the seeds; this sends out long branches, which twist about the

trees, and rise to a great height; the leaves are smooth, heart-shaped, ending in long points, and the ears at the base are large and rounded, standing upon long slender foot-stalks. The flowers come out on the opposite side of the stalks, upon long foot-stalks, each sustaining three flowers, with longer tubes than those of the former, and are of a deeper purple colour; this flowers from the latter end of June till the frost destroys it. As this is not so hardy as the former, the seeds should be sown upon a hot-bed in the spring, to bring the plants forward; and toward the end of May, they should be planted out in warm borders, and treated in the same manner as the former sort.

The sixth sort grows naturally in Africa and America; this is an annual plant, which rises with a twining stalk eight or ten feet high, garnished with heart-shaped leaves, divided into three lobes, which end in sharp points; these are woolly, and stand upon long foot-stalks; the flowers come out on long foot-stalks, each sustaining two flowers of a very deep blue colour, from whence it has been titled Anil or Indigo. This is one of the most beautiful flowers of this genus, and is undoubtedly a distinct species; though some have supposed it to be only a variety of the fourth sort, for I have cultivated it many years, and have never found it alter; the leaves of this having three deeply divided lobes, and those of the fourth sort being entire, is sufficient to determine the specific difference; this sort is annual, and must be propagated in the same manner as the fifth. It flowers all the latter part of summer, and, in good seasons, the seeds ripen well in the open air.

The seventh sort is that whose roots are eaten, and is generally titled Spanish Potatoe; these roots are annually imported from Spain and Portugal, where they are greatly cultivated for the table, but they are too tender to thrive well in the open air in England; they are cultivated by the roots in the same way as the common Potatoe, but require much more room; for these send out many trailing stalks, which extend four or five feet every way, and at their joints send out roots, which, in warm countries, grow to be large tubers, so that from a single root planted, forty or fifty large roots are produced. This plant is sometimes propagated by way of curiosity in England, but the roots should be planted on a hot-bed in the spring; and if the plants are kept covered in bad weather with glasses, they will produce flowers, and many small roots will be produced from the joints; but if they are exposed to the open air, they seldom make much progress.

The eighth sort grows naturally at La Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houstoun. This rises with a strong winding stalk to the height of twenty feet, dividing into several smaller, which fasten themselves about any of the neighbouring trees and shrubs; these are garnished with leaves in shape of a hand, having seven lobes, which are spear-shaped, and deeply cut on their borders, ending in sharp points. The flowers are single on each foot-stalk, which are very long. The empalement of the flower is large, spreading open, and is divided deeply into five parts. The flowers are large, of a purple colour, and are succeeded by large roundish seed-vessels, having three cells, in each of these is lodged a single seed.

This plant is tender, so the seeds should be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be transplanted each into a separate pot filled with light earth, and plunged into a moderate hot-bed, observing to shade them from the sun till they have taken new root; then they should have a large share of air admitted to them every day, to prevent their drawing weak, and also should have moderate waterings three or four times a week. When the plants are grown too tall to remain in the hot-bed, they must be shifted into larger pots, and placed in the bark-stove, where, if they are allowed room, they will rise to a great height, and produce flowers, but it rarely produces seeds in England.

The ninth sort is an annual plant. The seeds of this were sent me from Carthagena in New Spain, where the plant grows naturally. This rises with a twining slender stalk ten feet high, which is garnished with arrow-pointed leaves, whose ears at the base are rounded. The flowers are produced in small clusters, standing on long foot-stalks; these are yellow, and are succeeded by three-cornered seed-vessels, having three cells, in each of these are lodged two seeds.

This plant is annual, and too tender to thrive in the open air in England; so the seeds should be sown on a hot-bed in the spring, and the plants may be afterward treated in the same way as the eighth sort, with which management they will flower and produce ripe seeds.

The seeds of the tenth sort were sent me from Jamaica by the late Dr. Houstoun, who found the plants growing naturally there in great plenty. This is an annual plant, rising with slender, stiff, twining stalks, eight or nine feet high, garnished with heart-shaped leaves, which are downy. The flowers stand many together at the end of strong foot-stalks; these are purple, and are succeeded by roundish seed-vessels, with three cells, containing several small seeds.

This sort requires the same treatment as the eighth, being too tender to thrive in this country in the open air.

The eleventh sort was sent me from the island of Barbuda. This is an annual plant, which rises with twining stalks seven or eight feet high, garnished with oblong, oval, smooth leaves. The flowers come out at every joint on slender long foot-stalks, each supporting a large purple flower, whose empalement is cut almost to the bottom, in ten parts. The seeds and capsule are like those of the other species. This is a tender plant, so must be treated in the same manner as the eighth sort.

The twelfth sort grows naturally at Carthagena in New Spain, from whence I received the seeds. This is a perennial plant, which rises with strong winding stalks to the height of twelve or fourteen feet, and are garnished with leaves, divided into five lobes, standing upon short foot-stalks; the flowers stand upon long foot-stalks, each sustaining two purple flowers. The stalks, leaves, and every part of the plant, is closely covered with pungent stinging hairs, of a light brown colour. This sort is tender, so must be treated in the same way as the eighth.

The thirteenth sort grows naturally about Tohu in New Spain, from whence the seeds were sent me by the late Mr. Robert Millar. This hath a ligneous stalk covered with a purple bark, which twines about the trees, and rises to the height of thirty feet or more, and is garnished with leaves, which are deeply divided into five sharp-pointed lobes. The flowers stand upon long thick foot-stalks, which have a knee in the middle; they are very large, and of a purple colour; these are succeeded by round seed-vessels, as large as a middling Apple, divided into three cells, each containing two very large smooth seeds.

This plant is too tender to thrive in the open air in England, so must be treated in the same manner as the eighth sort, but it grows too tall for the stoves here. I have had these plants upward of twenty feet high, which have sent out many side branches, extending so wide on every side, as to cover most of the neighbouring plants, so that I was obliged to remove them into a cooler situation, where they would not thrive.

The fourteenth sort grows naturally on the sea shores in most of the islands in the West-Indies, where the stalks trail on the ground, which are garnished with oval leaves, indented at the top. The flowers are large, of a purple colour, and are produced by threes, on very long foot-stalks; these are succeeded by large oval seed-vessels, with three cells, each containing a single seed. This hath a perennial stalk, which trails on the ground, and spreads to a great distance, but is too tender to thrive in the open air in England, so must be treated in the same manner as the eighth sort, and

and may be continued two or three years in a warm stove; but it is apt to spread too far for a small stove, so that where there is not great room, it is not worthy of culture.

The fifteenth sort grows naturally in Jamaica; this rises with slender twining stalks eight or ten feet high; the leaves of these are shaped a little like those of the common great white Convolvulus, but the foot-stalks, which are pretty long, do each sustain many purple flowers, growing in bunches. The seed-vessels of this sort are three-cornered, and have three cells, each containing a single seed. This is an annual plant, which requires a hot-bed to raise it, and must be kept in a glass-case or a stove, otherwise the seeds will not ripen here.

The sixteenth sort has been long preserved in several curious gardens in England. It grows naturally in the Canary Islands; this hath a strong fibrous root, from which arise several twining woody stalks, dividing into many smaller; these, where they have support, will grow more than twenty feet high, and are garnished with oblong heart-shaped leaves, which are soft and hairy. The flowers are produced from the wings of the leaves, several standing upon one foot-stalk; these are for the most part of a pale blue, but there is a variety of it with white flowers. This plant flowers in June, July, and August, and sometimes ripens seeds here; but as the plants are easily propagated by layers, and also from cuttings, the seeds are not so much regarded; nor indeed will those plants which are raised by layers or cuttings produce seeds, though those which come from seeds seldom fail. As the leaves of this plant continue green all the year, the plants make a pretty variety in winter in the green-house; for it will not live abroad in winter in this country, though it only requires the same protection as Myrtles, and other hardy green-house plants. It may be propagated by laying down the young shoots in the spring, which generally put out roots in three or four months; then they may be taken from the old plants, and each planted in a separate pot filled with light earth, and placed in the shade till they have taken new root; after which they may be placed with other hardy green-house plants till autumn, when they should be removed into the green-house, and afterward treated in the same way as Myrtles, and other green-house plants. If the tender cuttings of this are planted during any of the summer months, in pots filled with light earth, and plunged into a moderate hot-bed, shading them from the sun, they will take root, and afterward should be treated as the layers.

The seventeenth sort is an annual plant; the seeds of it were sent me from Jamaica, where it grows naturally. This rises with a very slender twining stalk four or five feet high, garnished with triangular leaves, which are pointed. The flowers grow in clusters, sitting close to the stalks, which are blue, and are succeeded by seeds like those of the fourth sort. This sort will not ripen seeds in England, unless the plants are brought forward on a hot-bed in the spring, and afterward placed in a glass-case, where they may be defended from cold.

The eighteenth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houstoun. This is one of the most beautiful kinds, the flowers being very large, and of a fine Rose colour. It rises with a winding stalk seven or eight feet high, which is garnished with heart-shaped leaves, ending in long sharp points, sitting upon very long foot-stalks. The flowers also have long foot-stalks, each supporting two flowers, whose empalement is divided deeply into five parts; the seeds of this are large, and covered with a fine down. This is an annual plant, which is too tender to thrive in the open air in this country, so the seeds should be sown on a hot-bed in the spring, and the plants afterward treated in the same manner as is directed for the eighth sort.

The nineteenth sort grows naturally near the sea at Campeachy, from whence I received the seeds. This

hath strong, smooth, winding stalks, which send out roots at their joints, and are garnished with arrow-pointed leaves, whose ears or lobes are obtuse; the flowers are large, of a sulphur colour, and sit upon very long foot-stalks, which proceed from the side of the stalks, each supporting one flower, with a large swelling empalement; these are succeeded by large, smooth, oval capsules, having three cells, each including one large smooth seed. This is a perennial plant, whose stalks extend to a great distance, and put out roots at the joints, whereby it propagates in plenty; but it is too tender to thrive in England, unless it is preserved in a warm stove, where it requires more room than can well be allowed to one plant. It must be treated in the same manner as the eighth sort.

The twentieth sort grows naturally in Africa, from whence the seeds were sent to the royal garden at Paris, and from thence I received it in 1730. This rises with a slender winding stalk five or six feet high, garnished with heart-shaped arrow-pointed leaves; the flowers stand on long slender foot-stalks; these are white, with purple bottoms. This sort may be treated in the same manner as the common great Convolvulus.

The twenty-first sort grows naturally in Spain and Italy. This is an annual plant, which rises about two feet high, with slender twining stalks, garnished with oval leaves. The flowers are small, and of a bluish colour, each foot-stalk supporting one flower of little beauty, so is not often cultivated in gardens. If the seeds of this sort are permitted to scatter, the plants will rise in the spring, and require no other culture but to keep them clean from weeds; or if the seeds are sown in the spring, where the plants are to remain, they will flower in June, and the seeds will ripen in August.

The twenty-second sort grows naturally in Sicily, and also in the islands of the Archipelago. This hath a perennial root, which sends out many slender stiff stalks, twisting themselves round the neighbouring plants, and rise five or six feet high; these are garnished with leaves, which are divided into five or seven narrow lobes, and are of a soft texture, like fatten, standing on short foot-stalks. The flowers are produced from the side of the stalks upon long foot-stalks, which sustain two flowers of a pale Rose colour, with five stripes of a deeper red. This sort creeps at the root, so seldom produces seeds in England, but is propagated by shoots taken from the old plants. The best time for parting and transplanting these plants, is about the beginning of May, when they may be taken out of the green-house, and exposed in the open air; but the young plants which are separated from the old ones, should be placed under a frame, and shaded from the sun till they have taken new root; after which they must be gradually hardened to bear the open air, to which they must be exposed all the summer; but in autumn they must be placed in the green-house, and may be treated in the same way as the Canary Convolvulus before-mentioned.

The twenty-third sort hath some appearance of the twenty-second, and hath been supposed to be the same species by some writers; but I have cultivated both many years, and never have found either of them alter, so that I make no doubt of their being distinct plants. This sort hath a perennial root like the former, which sends out many weak twining stalks, rising about three feet high, twisting about the plants which stand near it, or about each other, and if they have no other support, fall to the ground; these are garnished with leaves of different forms, some are shaped almost like those of Betony, being slightly cut on their edges, others are almost heart-shaped, and are deeply cut on the sides, and some are cut to the midrib; they have a shining appearance like fatten, and are soft to the touch, standing on short foot-stalks. The flowers are produced on the opposite side from the leaves, having very long foot-stalks, each sustaining two flowers of a pale Rose colour, very like those of

of the former species. It flowers in June, July, and August, but rarely ripens seeds in England. It hath a perennial root, which sends out offsets, by which it is propagated in England, in the same manner as the last mentioned, and the plants must be treated in the same way.

The twenty-fourth sort grows naturally in Portugal, but hath been long cultivated in the flower-gardens in England for ornament; this is usually titled *Convolvulus Minor*, by the seedsmen and gardeners. It is an annual plant, which hath several thick herbaceous stalks, growing about two feet long, which do not twine like the other sorts, but decline toward the ground, upon which many of the lower branches lie prostrate; these are garnished with spear-shaped leaves, which sit close to the branches; the foot-stalks of the flowers come out just above the leaves at the same joint, and on the same side of the stalks; these are about two inches long, each sustaining one large open bell-shaped flower, which in some is of a fine blue colour, with a white bottom; in others they are pure white, and some are beautifully variegated with both colours. The white flowers are succeeded by white seeds, and the blue by dark-coloured seeds, and this difference is pretty constant in both; but those plants with variegated flowers, have frequently plain flowers of both colours intermixed with the striped; therefore the only method to continue the variegated sort, is to pull off all the plain flowers when they appear, never suffering any of them to remain for seed.

This sort is propagated by seeds, which should be sown on the borders of the flower-garden where they are designed to remain. The usual method is to put two or three seeds in each place where they are intended to flower, covering them half an inch with earth; and when the plants come up, if the seeds all grow, there should be but two left in each place, which will be sufficient; the others should be drawn out carefully, so as not to disturb the roots of those which are left; after which they will require no other culture but to keep them clean from weeds. If the seeds are sown in autumn, the plants will flower in May; but those which are sown in the spring, will not flower till about the middle of June, and will continue flowering till the frost stops them. The seeds ripen in August and September.

The twenty-fifth sort grows naturally in Italy and Sicily. This hath a perennial root, which runs deep in the ground, from which arise two or three upright branching stalks near two or three feet high, garnished with narrow leaves about two inches long, which sit close to the stalks; the foot-stalks of the flower proceed from the same place; these are four or five inches long, each sustaining four or five flowers, of a pale Rose colour, which spread open almost flat. This flowers in June and July, but seldom produces good seeds in England. It is propagated by seeds, which must be obtained from the countries where it naturally grows; these should be sown upon a warm dry border, where they are designed to remain; for as the plants run down with long tap-roots, they will not bear transplanting, for I have often made trial of this without any success. When the plants come up, they should be thinned where they grow too close, and afterward constantly kept clean from weeds, which is all the culture it will require. It flowers in July and August, and the stalks decay in autumn; but the roots will last several years, and if they are in a dry soil and warm situation, will abide through the winters very well without covering. I have received a variety of this from Nice, where it grows naturally, with broader leaves, which are hairy. The flowers are placed all toward the top of the stalk upon long foot-stalks, growing many together very closely joined: but I cannot be sure if it is not a feminal variation, for it was sent me by the same title.

The twenty-sixth sort grows naturally in France; this hath a perennial creeping root, from which arise several short branching stalks about four inches high, garnished with spear-shaped silky leaves; the flowers

are produced on the side, and at the top of the stalks, in small clusters, sitting close together; these are much smaller than those of the former sort, but are of a deeper Rose colour: this seldom produces seeds in England; but the roots propagate in plenty. It delights in a light dry soil, and requires no other care but to keep the plants clean from weeds; it may be transplanted either in the spring or autumn. This is by some supposed to be the same as the last mentioned sort, but whoever has cultivated them, can have no doubt of their being different species.

The twenty-seventh sort grows naturally in Italy, Sicily, and the islands in the Archipelago. It rises with upright shrubby stalks about three feet high, closely garnished with blunt, spear-shaped, silky leaves, which are placed on every side the stalks; they are near two inches long, and a quarter broad, rounding at their ends. The flowers are produced in clusters at the top of the stalks, sitting very close; they are of a pale Rose colour, and come out in June and July, but do not perfect seeds in England. This plant will live in the open air in mild winters, if it is planted in a light soil and a warm situation, but in hard winters it is destroyed; therefore some of the plants should be kept in pots, and sheltered under a common frame in winter, where it may enjoy the free air in mild weather, and be protected from the frost, and in summer placed abroad with other hardy exotic plants, where its fine silky leaves will make a pretty appearance. It may be propagated by laying down the branches, and also by cuttings, but both very seldom put out roots the same year, and many of them will fail; so that the best way is to procure the seeds from Italy, for those plants which come from seeds, grow much larger than those which are propagated the other way.

The twenty-eighth sort grows naturally in Candia, and several of the islands in the Archipelago. This hath a perennial root, which sends up several erect branching stalks about two feet high, which are garnished with very narrow-pointed leaves, sitting close to the stalks, which are hoary. The flowers come out singly on the side of the stalks, sitting very close to them, having scarce any foot-stalks; these are of a very pale bluish colour, and spread open almost to the bottom. It flowers in June and July, but rarely produces any seeds in England.

This sort is propagated in the same manner as the twenty-fifth, and the plants require the same treatment. This plant must have a dry soil and a warm situation, otherwise it will not live through the winter in the open air in England. As the stalks of this sort decay in autumn, so if the surface of the ground about their roots is covered with some old tanners bark, it will preserve them in the hardest frosts.

The twenty-ninth sort is used in medicine. This is stiled *Soldanella*, and *Brassica marina*; it grows naturally on the sea beaches in many parts of England, but cannot be long preserved in a garden. This hath many small, white, stringy roots, which spread wide, and send out several weak trailing branches, which twine about the neighbouring plants like the common Bindweed, and are garnished with kidney-shaped leaves about the size of those of the lesser Celandine, standing upon long foot-stalks, and are placed alternate. The flowers are produced on the side of the branches at each joint. These are shaped like those of the first sort, and are of a reddish purple colour; they appear in July, and are succeeded by round capsules, having three cells, each containing one black seed; every part of the plant abounds with a milky juice. This is esteemed a good medicine to purge off watery humours, and is prescribed in dropsies.

The thirtieth sort grows naturally in the island of Ceylon. This is a perennial plant, having thick fleshy roots, which spread far in the ground, and abound with a milky juice, which flows out when the roots are broken or wounded, and soon hardens into a resinous substance, when exposed to the sun and air. From the root shoots forth many twining branches,

which twist about each other, or the neighbouring plants, like the common Bindweed. These are garnished with heart-shaped leaves, which are soft to the touch, like those of the Marsh Mallow. The flowers are produced at the joints on the side of the stalks, several standing together on the same foot-stalk; they are white, and shaped like those of the common great Bindweed. These are succeeded by round capitules, having three cells, which contain two seeds in each.

The roots of this plant, which is the only part used in medicine, are brought to us from India. It is titled Turpethum, or Turbith in the shops.

This plant is tender, so will not live in the open air in England; it is propagated by seeds, which must be sown on a hot-bed; and when the plants are fit to remove, they should be each planted in a separate pot, and plunged into a hot-bed of tanners bark, and screened from the sun till they have taken fresh root, and afterward must be treated in the same manner as hath been directed for the eighth sort.

The thirty-first sort is the Jalap which is used in medicine. This grows naturally at Aleppo, in the Spanish West-Indies, situated between La Vera Cruz and Mexico. The root of this plant hath been long used in medicine, but it was not certainly known, what plant it was produced from. The old title of this was Mechoacana nigra, but father Plumier asserted that it was the root of one species of Marvel of Peru; from whence Tournefort was induced to constitute a genus from that plant, under the title of Jalapa. But Mr. Ray, from better information, put it among the Convolvuli, and titled it Convolvulus Americanus, Jalapium dictus. This was by the late Dr. Houstoun certainly ascertained, who brought some of the roots of this plant from the Spanish West-Indies to Jamaica, where he planted them, with a design of cultivating the plants in that island, where he observed them to thrive, during his abode there: but soon after he left the country, the person to whose care he committed them, was so careless as to suffer hogs to root them out of the ground, and destroy them; so that there was no remains of them left, when he returned there; nor have I heard of this plant being introduced into any of the British islands since.

A few years past I received a few of the seeds of this plant, which succeeded in the Chelsea garden, where the plants thrived very well, but did not produce any flowers. This hath a large root of an oval form, which is full of a milky juice; from which come out many herbaceous triangular twining stalks, rising eight or ten feet, garnished with variable leaves, some of them being heart-shaped, others angular, and some oblong and pointed. They are smooth, and stand upon long foot-stalks; and from a drawing of the plant, made by a Spaniard in the country, where it grows naturally, who gave it to Dr. Houstoun, and is now in my possession, the flowers are shaped like those of the common Great Bindweed, each foot-stalk supporting one flower. But as it is only a pencil drawing, so the colour is not expressed, therefore I can give no farther account of it. The seeds of this are covered with very white down like cotton.

As this plant is a native of a warm country, so it will not thrive in England, unless it is preserved in a warm stove; therefore the seeds must be sown on a hot-bed, and the plants put into pots, and plunged into a hot-bed of tanners bark, and treated in the same manner as the eighth sort; with this difference only, that as this hath large, fleshy, succulent roots, so they should have but little water given them, especially in winter, lest it cause them to rot. They should be planted in light sandy earth not too rich, for the same reason, and the plants should always remain in the bark-stove.

The root of Jalap is esteemed an excellent cathartic medicine, purging serous watery humours especially, and is of singular service in dropsies, and for rheumatic disorders. But the quantity of the root which is used in medicine, is not sufficient to render the in-

roduction of this plant into the British colonies, a matter of great concern. But since the distillers and brewers have found out its use for exciting a fermentation, the consumption of it is now so great, as that it would become a national benefit, if it were produced in the British islands; which might be soon effected, were the inhabitants of those islands a little more attentive to their own, and the public benefit.

CONYZA. Lin. Gen. Plant. 854. Tourn. Inst. R. H. 454. tab. 259. [of Káwōf, Gr. because the leaves, being hung up, drive away gnats and fleas, as Dioscorides says:] Flea-bane.

The CHARACTERS are,

It hath a compound flower, made up of many hermaphrodite florets, which compose the disk; and female half florets, which are ranged round the border, and form the rays; the hermaphrodite florets are funnel-shaped, and cut into five parts at the brim, which spread open; these have each five short hairy stamina, terminated by cylindrical summits; in the bottom of each floret is situated a germen supporting a slender style, crowned by a bifid stigma. The female half florets or rays, are funnel-shaped, and cut into three parts at the top; these have a germen, with a slender style, terminated by two slender stigmas, but have no stamina. All these are included in a common scaly empalement, which is oblong and square; the scales are pointed, and the outer ones spread open. The hermaphrodite and female florets, are each succeeded by one oblong seed, crowned with down, sitting upon a plain receptacle, and are included in the empalement.

This genus of plants is ranged in the second section of Linnaeus's nineteenth class, intitled Syngenia Polygamia superflua. The plants of this section have hermaphrodite and female florets, which are both fruitful.

The SPECIES are,

1. CONYZA (*Squarrosa*) foliis lanceolatis acutis, caule annuo corymboso. Hort. Cliff. 405. *Flea-bane with pointed spear-shaped leaves, an annual stalk, and flowers growing in roundish bunches.* Conyza major vulgaris. C. B. P. 265. *Common greater Flea-bane.*
2. CONYZA (*Bifrons*) foliis ovato oblongis, amplexicaulis. Hort. Cliff. 405. *Flea-bane with oblong oval leaves embracing the stalks.* Eupatoria Conyzoides maxima Canadensis, foliis caulem amplexantibus. Pluk. Alm. 141.
3. CONYZA (*Candidis*) foliis ovatis tomentosis, floribus confertis, pedunculis lateralibus terminalibusque. Hort. Cliff. 405. *Flea-bane with oval woolly leaves, flowers growing in clusters, and foot-stalks proceeding from the sides and terminating the stalks.* Conyza Cretica fruticosa, folio molli candidissimo & tomentoso. Tourn. Cor. 33.
4. CONYZA (*Lobata*) foliis inferioribus trifidis, superioribus ovato lanceolatis obsolete serratis floribus corymbosis. Hort. Cliff. 405. *Flea bane whose under leaves are trifid, those above oval and spear-shaped, and flowers growing in round bunches.* Conyza arborecens lutea, folio trifido. Plum. Cat. 9.
5. CONYZA (*Tomentosa*) arborecens, foliis oblongo ovatis, tomentosis, subtus cinereis, floribus terminalibus pedunculis racemosis. *Tree Flea-bane with oblong woolly leaves, of an Ash colour on their under side, and flowers terminating the branches, standing upon branching foot-stalks.* Conyza arborecens, tomentosa, foliis oblongis, floribus in summitatibus racemorum, ramosis sparsis albicantibus. Houst. MSS.
6. CONYZA (*Salicifolia*) foliis linearibus decurrentibus serratis, floribus corymbosis terminalibus. *Flea-bane with narrow running leaves, and flowers in round bunches terminating the stalks.* Conyza herbacea, caule alato, Salicis folio, floribus umbellatis purpureis minoribus. Houst. MSS.
7. CONYZA (*Corymbosa*) arborecens, foliis lanceolatis, floribus corymbosis, terminalibus pedunculis racemosis. *Tree Flea-bane with spear-shaped leaves, and flowers growing in round bunches at the end of the shoots, having branching foot-stalks.* Conyza arborecens, foliis oblongis floribus singulis tribus flosculis constantibus. Houst. MSS.

8. **CONYZA** (*Viscosa*) caule herbaceo, foliis ovatis serratis, villosis, floribus alaribus & terminalibus. *Flea-bane with an herbaceous stalk, oval, sawed, hairy leaves, and flowers proceeding from the sides, and at the ends of the branches.* Conyza odorata, Bellidis folio villosa & viscosa: Houst. MSS.
9. **CONYZA** (*Arborescens*) foliis ovatis integerrimis acutis subtus tomentosis, spicis recurvatis secundis, bracteis reflexis. Lin. Sp. 1209. *Flea-bane with entire oval-pointed leaves, woolly on their under side, recurved abounding spikes of flowers, and reflexed bractea.* Conyza fruticosa, flore pallide purpureo, capitulis & lateribus ramulorum spicatum exeuntibus. Sloan. Cat. Jam. 124.
10. **CONYZA** (*Symphytifolia*) foliis oblongo ovatis scabris, floribus racemosis terminalibus, caule herbaceo. *Flea-bane with oblong, oval, rough leaves, flowers growing in bunches at the ends of the branches, and an herbaceous stalk.* Conyza Symphyti facie, flore luteo. Houst. MSS.
11. **CONYZA** (*Scandens*) foliis lanceolatis scabris, nervosis sessilibus, racemis recurvatis, floribus adscendentibus, pedunculis lateralibus caule fruticoso scandente. *Flea-bane with rough, nervous, spear-shaped leaves sitting close to the branches, recurved spikes, with flowers standing upward, foot-stalks proceeding from the side of the branches, and climbing shrubby stalks.* Conyza Americana scandens, Lauri folio aspero, floribus spicatis albis. Houst. MSS.
12. **CONYZA** (*Trinerviis*) foliis ovatis glabris, trinerviis integerrimis, floribus spicatis terminalibus, caule fruticoso. *Flea-bane with oval smooth leaves, which have three veins and are entire, flowers growing in spikes at the ends of the branches, and a shrubby stalk.* Conyza Americana frutescens, foliis ovatis trinerviis & integris, floribus spicatis albis. Houst. MSS.
13. **CONYZA** (*Uniflora*) foliis lanceolatis acutis sessilibus, floribus singulis lateralibus, calycibus coloratis, caule fruticosoramoso. *Flea-bane with pointed spear-shaped leaves sitting close to the branches, single flowers on the side of the branches, which have coloured empalements, and a shrubby branching stalk.* Conyza Americana frutescens foliis oblongis acutis, capitulis & ramulorum exeuntibus, calycibus purpurascens. Houst. MSS.
14. **CONYZA** (*Spicata*) fruticosa foliis ovatis trinerviis, floribus spicatis alaribus. *Shrubby Flea-bane with oval leaves having three nerves, and flowers growing in spikes from the side of the branches.*
15. **CONYZA** (*Pedunculata*) foliis ovato lanceolatis trinerviis, pedunculis longissimis terminalibus floribus corymbosis. *Flea-bane with oval spear-shaped leaves having three veins, foot-stalks which are very long terminating the branches, and flowers growing in round bunches.*
16. **CONYZA** (*Baccharis*) foliis ovato oblongis, obtusis serratis, semiamplexicaulibus, floribus corymbosis terminalibus. *Flea-bane with oblong oval leaves which are obtuse and sawed, half embracing the stalks with their base, and flowers in round bunches terminating the stalks.* Eupatorium Conyzoides Sinica Baccharidis folio rarius crenato, summo caule ramoso, floribus parvis coronato. Pluk. Amath. 80.
17. **CONYZA** (*Odorata*) foliis lanceolatis serratis, petiolatis, caule fruticoso ramoso, floribus corymbosis terminalibus. *Flea-bane with spear-shaped sawed leaves having foot-stalks, and flowers growing in round bunches at the end of the branches.* Conyza major odorata sive Baccharis floribus purpureis nudis. Sloan. Cat. Jam. 121.
18. **CONYZA** (*Hirsuta*) foliis ovalibus integerrimis scabris subtus hirsutis. Lin. Sp. 1209. *Flea-bane with oval, entire, rough leaves, hairy on their under side.* The first sort grows naturally upon dry places in several parts of England, so is seldom allowed a place in gardens. This is a biennial plant, which decays soon after the seeds are ripe; it hath several large, oblong, pointed leaves, growing near the ground, which are hairy; between these the stalks come out, which rise two feet and a half high, dividing upward into several branches, garnished with smaller oblong leaves,

standing alternate; at the ends of the stalks the flowers are produced in round bunches, which are of a dirty yellow colour; these are succeeded by oblong seeds, crowned with down. It flowers in July, and the seeds ripen in autumn. If the seeds are permitted to scatter, the plants will come up the following spring, and require no other care but to keep them clean from weeds.

The second sort grows naturally on the mountains in Italy, and is preserved in botanic gardens for the sake of variety. This hath a biennial root but an annual stalk. From a thick fibrous root arise many upright stalks, garnished with oblong oval leaves, which are rough, and embrace the stalks with their base; these have appendages running along the stalk, from one to the other, whereby the stalk is winged. The upper part of the stalks divide into many smaller branches, garnished with leaves of the same form as the other, but smaller, standing alternate; the branches and main stalks, are terminated by yellow flowers growing in round bunches; these are succeeded by oblong seeds, crowned with down. It flowers in July, and the seeds ripen in autumn. This is propagated by seeds, which may be sown on a bed of light earth in the spring, and when the plants come up, they should be thinned where they are too near, and kept clean from weeds; the following autumn they may be transplanted where they are designed to remain, and require no other care but to keep them clean from weeds. The second year they will flower and produce ripe seeds, and will continue two years if the soil is not too good, for these plants often rot, when they are planted in a rich soil.

The third sort grows naturally in Crete. This hath a short shrubby stalk, which in this country seldom rises more than six inches high, dividing into several short branches, which are closely garnished with oval, woolly, very white leaves; from these branches arise the flower-stalks, which are woolly, about nine inches high, garnished with small, oval, white leaves, placed alternate. The flowers are produced at the sides, and end of the stalk, sometimes but one, at other times two, and sometimes three flowers standing on the same foot-stalk. They are of a dirty yellow colour, and appear in July, but rarely are succeeded by seeds in this country; so the plant is propagated here by slips, which, if taken from the old plants in June, and planted on an east-aspected border, and covered with hand-glasses, will take root in six or eight weeks. But these slips must be frequently, but gently refreshed with water, and the glasses should be shaded in hot weather; and after they have been planted a fortnight, the glasses should be raised on one side to admit air to the cuttings; and when they have taken root, they should be gradually exposed to the open air. In autumn these should be carefully taken up, preserving the earth to their roots; some of them may be planted in pots, that they may be sheltered under a frame in the winter; and the others should be planted in a warm border of dry poor earth, where they will endure the cold of our ordinary winters very well, and continue many years. This is preserved in gardens, more for the beauty of its silvery leaves than its flowers, which have not much to recommend them.

The fourth sort grows naturally in Jamaica, from whence it was sent me by the late Dr. Houstoun. This is titled by Sir Hans Sloane *Virga aurea major*, sc. *Herba Doria folio sinuato hirsuto*. Cat. Jam. 125. It rises with a shrubby stalk seven or eight feet high, dividing into several branches, garnished with rough leaves four inches long, shaped like the point of a halbert. The flowers are produced in roundish bunches, at the extremity of the branches; they are yellow, and stand close together. These are succeeded by oblong seeds crowned with down.

This plant is too tender to thrive in the open air in this country, therefore the seeds must be sown upon a hot-bed; and when the plants are fit to remove, they must be each transplanted into a separate small pot

pot filled with light sandy earth, and plunged into a hot-bed, observing to screen them from the sun till they have taken new root; then they must have free air admitted to them every day, in proportion to the warmth of the season; they must also be frequently watered in warm weather, but they should not have it in too great plenty. As the plants advance in strength, so they must have a greater share of air; and if the season is warm, they may be exposed to the open air for a few weeks in the heat of summer, provided they are placed in a warm situation; but if the nights prove cold, or much wet should fall, they must be removed into shelter: if these plants are placed in a moderate stove in winter, they will thrive better than in greater heat, and in summer they should have a large share of air. With this management I have had the plants flower well in July, though they have not perfected seeds here.

The fifth sort rises with a woody stalk ten or twelve feet high, dividing into many branches, whose bark is covered with a brown down; these are garnished with oblong oval leaves, which are green on their upper side, but of an Ash colour on their under, placed alternate, on short foot-stalks. The flowers are produced at the end of the branches, upon long branching foot-stalks, in loose spikes ranged on one side; they are white, and are succeeded by long flat seeds crowned with down. This plant grows naturally at La Vera Cruz in New Spain, from whence Dr Houstoun sent me the seeds. It is a tender plant, so must be treated in the same manner as hath been directed for the former sort.

The sixth sort grows naturally at La Vera Cruz in New Spain. This hath a perennial root, from which arise several upright stalks three feet high, garnished with long narrow leaves, sawed on their edges, placed alternate, and have appendages which run along the stalk from one to the other, forming a border or wing to the stalks. The flowers are produced at the end of the stalks in round bunches, they are small, and of a purple colour, and are succeeded by oblong flat seeds, crowned with down. This is propagated by seeds, which must be sown upon a hot-bed in the spring, and the plants must afterward be transplanted into pots, and plunged into a fresh hot-bed, observing to screen them from the sun till they have taken fresh root; after which they must have a large share of air, and about Midsummer they may be placed in the open air in a sheltered situation, where they may remain till the end of September, when they should be removed into the stove, and during the winter kept in a temperate degree of warmth. The second year these plants will flower, but they do not perfect seeds in England. The seventh sort was sent me from La Vera Cruz by the late Dr. Houstoun, who found it growing there naturally. This hath a strong woody stem, which rises to the height of fourteen or sixteen feet, covered with an Ash-coloured bark, and is divided upward into many ligneous branches, garnished with spear-shaped leaves standing alternate, on short foot-stalks. These branches are terminated by roundish bunches of white flowers, sitting upon long foot-stalks, several of them being joined on the same foot-stalk. These are not succeeded by seeds in England, so that the seeds must be procured from abroad, and these must be sown on a hot-bed, and the plants afterward treated in the same manner as the fourth sort.

The eighth sort grows naturally at La Vera Cruz, from whence it was sent me by the late Dr. Houstoun; this is an annual plant, which grows in low moist places; where the water stands in winter; it hath an herbaceous branching stalk, which rises about one foot high, garnished at each joint with one oval leaf, sitting close to the branches; these are sawed on their edges, and covered with a white hairy down. The flowers are produced from the side of the branches on slender foot-stalks, each for the most part sustaining three flowers, which are white, and are succeeded

by chaffy seeds, crowned with down; the whole plant is viscous, and will stick to the fingers of those who handle it.

The seeds of this plant must be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each transplanted into a separate pot, and plunged into a fresh hot-bed, and treated in the same manner as the other tender sorts, but must have a large share of air in warm weather, and frequently refreshed with water. In July these plants will flower, and if the autumn proves favourable, they will ripen their seeds; a plant or two of this sort may be preserved for the sake of variety, but there is little beauty in it.

The ninth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houstoun; this rises with a shrubby stalk six or seven feet high, dividing into many ligneous branches, which have a mealy bark, and garnished with spear-shaped leaves, sitting close to the branches; they are hairy, and of a silver colour on their under side, and are placed alternate. The flowers come out from the side of the branches, generally in loose spikes, which grow horizontal, and stand on the upper side erect; but sometimes they come out single, sitting close between the leaf and branch; these are of a pale purple colour, and are succeeded by chaffy seeds, crowned with a down.

This sort is propagated by seeds, which must be obtained from the country where it grows naturally, for it doth not produce seeds in England, though it has flowered several years in the Chelsea garden; the seeds must be sown, and the plants afterward treated in the same manner as hath been before directed for the fourth sort.

The tenth sort grows naturally at La Vera Cruz, from whence it was sent me by the late Dr. William Houstoun; this hath a perennial root, and an annual stalk. It grows about three feet high; the leaves are from four to five inches long, and one and a half broad in the middle, and are rough like those of Comfrey. The stalks are terminated by branching flower-stalks, each foot-stalk sustaining several yellow flowers, not much unlike those of the common sort. This is propagated by seeds in the same manner as the sixth sort, and the plants must be treated in the same way. It will flower the second year, but it doth not ripen seeds in England.

The eleventh sort was sent me from La Vera Cruz by the late Dr. Houstoun; this hath a climbing shrubby stalk, which rises fourteen or sixteen feet high, and divides into many branches, garnished with leaves about the size of those of the Bay-tree, and full as thick in their texture, having many deep transverse nerves, running from the midrib to the sides; they are of a pale green colour. The flowers are produced in long spikes, ranged on the upper side of the spike only, which come out from the side of the branches, pointed upward; these are large and white, and are succeeded by flat dark-coloured seeds, crowned with down.

This plant makes a fine appearance in the stove when it flowers, and as it retains its leaves all the year, so in the winter season it affords an agreeable variety among other tender plants. The culture of this plant is the same as hath been directed for the fourth sort, so need not be repeated.

The twelfth sort was sent me from Carthage in New Spain, where it grows naturally, by the late Mr. Robert Millar, surgeon; this rises with a shrubby stalk six or seven feet high, dividing into several ligneous branches, garnished with oval, smooth, entire leaves, having three longitudinal veins, placed alternate, close to the branches. The flowers are produced in short close spikes at the end of the branches; these are white, and are succeeded by oblong flat seeds, crowned with down; this sort is tender, so must be treated in the same manner as the fourth, and will abide several years with this management.

The

The thirteenth sort grows naturally in the same country as the last mentioned, and was sent me by the same gentleman; this rises with a shrubby stalk eight or ten feet high, dividing into many long slender branches, garnished with spear-shaped leaves, three inches long, and three quarters of an inch broad in the middle, ending in acute points; the smaller branches are set with very narrow, oblong, pointed leaves, which grow close to the stalks; and at each joint is produced one pretty large white flower, with a purple empalement; these flowers come out the whole length of the small branches, sitting close to the base of the leaves, so that the plants make a pretty appearance in flower. This may be propagated in the same way as the fourth, and with that management it hath flowered very well, but it doth not produce seeds in England.

The fourteenth sort was sent me from Carthagena by the before-mentioned gentleman, who found it growing there in great plenty. This hath a strong woody stem, rising ten or twelve feet high, divided upward into many short ligneous branches, whose joints are very close to each other. The leaves come out alternate on every side the branches, to which they sit very close; they are smooth, one inch long, and half an inch broad, ending in acute points, having three longitudinal veins. The flowers are white, and produced in short close spikes, which come out from the side of the branches, and are succeeded by oblong flat seeds, crowned with down.

This is a tender plant, so requires the same treatment as the fourth sort, with which it hath flowered very well, but hath not produced seeds in England.

The fifteenth sort rises with a shrubby stem to the height of six or seven feet, dividing into several branches, which have a dark brown bark, and are closely garnished with oval, spear-shaped, smooth leaves, having three longitudinal veins, standing on short foot-stalks, placed alternate on every side the branches. The flowers are produced on long naked foot-stalks, which extend five or six inches beyond the end of the branches; these are purple, and form a kind of round bunch: the empalement of the flower is composed of short chaffy scales.

This grows naturally at Campeachy, from whence the seeds were sent me by Mr. Robert Millar. It is a tender plant, so must be treated in the same way as is directed for the fourth sort, with which it hath flowered, but hath not produced seeds in this country.

The sixteenth sort grows naturally at Campeachy, from whence I received the seeds; this rises with a shrubby stalk to the height of ten or twelve feet, sending out many strong ligneous branches, covered with a dark-coloured bark, garnished with oblong, oval, blunt leaves, sawed on their edges, and half embrace the stalks with their base: the flowers are purple, growing in round bunches at the end of the branches, and are succeeded by flat seeds, crowned with down.

This is also a tender plant, and requires the same treatment as the fourth sort, with which it hath flowered, but doth not produce seeds in England.

If the seeds of these plants are sown in autumn soon after they are ripe, there is no danger of their miscarriage; but as these are most of them brought from abroad, they do not arrive here in good time, so the plants rarely come up the first year; therefore the seeds should be sown in pots, that they may be preserved through the winter, and the following spring the plants will come up.

The seventeenth sort grows naturally in Jamaica; this rises with a shrubby branching stalk about four or five feet high. The lower branches and stalk are garnished with spear-shaped leaves about four inches long, and one broad in the middle; they are sawed on their edges, and have short foot-stalks; the leaves on the upper branches are much narrower, and end in acute points. The flowers are purple, and are produced in round bunches at the end of the branches, and are succeeded by downy seeds like the other spe-

cies. This is tender, and requires the same culture as the fourth sort.

The seventeenth sort grows naturally in China: this is a biennial plant, which perishes soon after the seeds are ripe. The stalks are hairy, rising about two feet high, garnished with oblong oval leaves, which are entire, rough on their upper side, but have many strong pale hairs on their under, placed alternately on the branches. The flowers are purple, coming out from the side of the branches in oblong spikes.

This sort is propagated by seeds, which should be sown in pots in the autumn, if they can be procured at that season; but the pots should be placed in a garden-frame in winter, to prevent the seeds suffering by cold and wet. If the seeds are sown in the spring, the plants rarely come up the same year, therefore it will be proper to screen this in winter; when this is observed, the plants will rise the following spring. When the plants are fit to remove, they should be each planted in a separate pot, and placed into a very moderate hot-bed, where they must be screened from the sun until they have taken root; after which they should be gradually hardened to bear the open air, into which they should be removed the beginning of June, placing them in a sheltered situation, where the second season they will flower, and if the summer is good, they will ripen their seeds.

CONSERVATORY. See GREEN-HOUSE.

CONVAL LILY. See CONVALLARIA.

COPAIFERA, the balsam of Capevi.

The CHARACTERS are,

It hath no empalement; the flower consists of five leaves, which expands in form of a Rose; it hath ten short stamina, crowned by long summits. The pointal is fixed in the center of the flower, which afterward becomes a pod, in which are contained one or two seeds, which are surrounded with a pulp of a yellow colour.

We know but one sort of this tree, which is,

COPAIFERA (*Officinalis*) foliis pinnatis. *The balsam of Capevi.*

This tree grows near a village called Ayapel, in the province of Antiochi, in the Spanish West-Indies; this is about ten days journey from Carthagena. There are great numbers of these trees in the woods about this village, which grow to the height of fifty or sixty feet. Some of these trees do not yield any of the balsam, those which do are distinguished by a ridge which runs along their trunks; the trees are wounded in their center, and they place calabash shells, or some other vessels to the wounded part to receive the balsam, which will all flow out in a short time. One of these trees will yield five or six gallons of the balsam; but though these trees will thrive well after being tapped, yet they never afford any more balsam.

As this balsam is used in medicine, it deserves our application to procure the trees, and cultivate them in some of the English colonies of America; for as the English are possessed of lands in so many different latitudes, they might cultivate most kinds of trees and plants from the different parts of the world, which are useful in medicine, dyeing, or for any other purpose of life.

The seeds of this tree were brought from the country of their growth by Mr. Robert Millar, surgeon, who sowed a part of them in Jamaica, which he informed me had succeeded very well; so that we may hope to have these trees propagated in great plenty in a few years, in some of the English colonies, if the slothfulness of the inhabitants doth not suffer them to perish, as they have the Cinnamon-tree, and some other useful plants, which have been carried thither by curious persons.

There are not at present any of these trees in Europe, that I can learn; for those seeds which Mr. Millar sent over to England, were all destroyed by insects in their passage, so that not one succeeded in the several places where they were sown; but could fresh seeds be procured, the plants might be raised in England, and preserved in the bark-stoves very well; for the country of their growth is much more temperate than many others, from whence we have been fur-

fur-

furnished with a great variety of plants, which succeed very well in the stoves, and some of them arrive to a great degree of perfection.

CORALLODENDRON. See ERYTHRINA.

CORCHORUS. Lin. Gen. Plant. 675. Tourn. Inst. 259. tab. 135. Jews Mallow.

The CHARACTERS are,

The empalement of the flower is composed of five narrow spear-shaped leaves, which are erect. The flower hath five oblong blunt petals, which are no longer than the empalement. It hath many hairy stamina, which are shorter than the petals, terminated by small summits. In the center is situated an oblong furrowed germen, supporting a short thick style, crowned by a bifid stigma. The germen afterward becomes a cylindrical pod having five cells, which are filled with angular-pointed seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, intitled Polyandria Monogynia, the flowers having many stamina and but one style.

The SPECIES are,

1. CORCHORUS (*Olivarius*) capsulis oblongis, ventricosus, foliorum infimis serraturis setaceis. Lin. Flor. Zeyl. 213. *Jews Mallow with oblong swelling pods, and the saws on the under side of the leaves terminating with bristles.* Corchorus five Melochia. J. B. 2. 982. *Common Jews Mallow.*
2. CORCHORUS (*Æstivans*) capsulis oblongis, sexsulcatis sexcuspidatis, foliis cordatis infimis serraturis setaceis. Lin. Sp. 746. *Jews Mallow with oblong furrowed pods, heart-shaped leaves, whose saws terminate with bristles.* Corchorus Americana, carpini foliis, sextuplici capsula prælonga. Pluk.
3. CORCHORUS (*Capsularis*) capsulis subrotundis, depressis, rugosis. Flor. Zeyl. 214. *Jews Mallow with roundish depressed capsules which are rough.* Corchorus Americana, prælongis foliis, capsula striata subrotunda brevi. Pluk.
4. CORCHORUS (*Tetragonis*) foliis ovato-cordatis crenatis, capsulis tetragonis, apicibus reflexis. *Jews Mallow with oval heart-shaped leaves which are crenated, and four-cornered capsules, whose points are reflexed.* Corchorus flore flavo, fructu carophylloide. Pluk.
5. CORCHORUS (*Linearibus*) foliis lanceolatis, serrato dentatis, capsulis linearibus, compressis, bivalvibus. *Jew Mallow with spear-shaped leaves, which are indented like the teeth of a saw, and narrow, compressed, bivalvular pods.*
6. CORCHORUS (*Bifurcatis*) foliis cordatis, serratis, capsulis linearibus, compressis, apicibus bifurcatis. *Jews Mallow with heart-shaped sawed leaves, and narrow compressed pods, whose points have two horns.*
7. CORCHORUS (*Siliquosus*) capsulis linearibus compressis, foliis lanceolatis æqualiter serratis. Lin. Sp. 746. *Jews Mallow with compressed capsules, and spear-shaped leaves equally sawed on their edges.* Corchorus Americana, foliis & fructu augustioribus. Tourn. Inst. R. H. 259.
8. CORCHORUS (*Hirsuta*) capsulis subrotundis lanatis, foliis ovatis obtusis tomentosis æqualiter serratis. Lin. Sp. 747. *Jews Mallow with roundish downy pods, and obtuse, oval, woolly leaves, which are equally sawed on their edges.* Corchoro affinis Chamædryos folio, flore stamineo, feminioribus atris quadrangulis duplici serie dispositis. Sloan. Cat. 50.

The first species, Rauwolf says, is sown in great plenty about Aleppo, as a pot-herb, the Jews boiling the leaves of this plant to eat with their meat; this he supposes to be the Olus Judaicum of Avicenna, and the Corchorum of Pliny.

This plant grows in the East and West-Indies, from both which places I have several times received the seeds. In the East-Indies the herb is used in the same manner as in the Levant, as I have been informed; but I do not hear that it is used by the inhabitants of America.

It is an annual plant, which rises about two feet high, dividing into several branches, garnished with leaves of different sizes and forms; some are spear-shaped, others are oval, and some almost heart-shaped; they

are of a deep green, and slightly indented on their edges, having near their base two brittle segments, which are reflexed. They have very long slender foot-stalks, especially those which grow on the lower part of the branches. The flowers sit close on the opposite side of the branches to the leaves, coming out singly; they are composed of five small yellow petals, and a great number of stamina surrounding the oblong germen, which is situated in the center of the flower, and afterward turns to a rough swelling capsule, two inches long, ending in a point, opening in four cells, which are filled with angular greenish seeds. This plant flowers in July and August, and the seeds ripen in autumn.

The second sort grows naturally in several islands of the West-Indies, from whence the seeds have been sent me; this is also an annual plant, which rises with a strong herbaceous stalk two feet high, divided upward into two or three branches, garnished with heart-shaped leaves, sawed on their edges, standing upon long foot-stalks; and between these are several smaller leaves nearly of the same form, sitting close to the branches. The flowers come out singly on the side of the branches, as the other, which are shaped like them, and are succeeded by longer swelling pods, which are rough, and have four longitudinal furrows, these open into four parts at the top, and contain four rows of angular seeds. It flowers and seeds at the same time with the former sort.

The third sort grows naturally in both Indies; I have received the seeds of this from several parts of India and America, this is also an annual plant, which rises with a slender herbaceous stalk about three feet high, sending out several weak branches, which are garnished at each joint by one leaf of an oblong heart-shape, ending in a long acute point, and are sawed on their edges, standing upon short foot-stalks. The flowers come out singly on the side of the branches, to which they sit very close; they are smaller than those of the former sorts, and are succeeded by short roundish seed-vessels, which are rough, and flattened at the top, having six cells filled with small angular seeds. This flowers and seeds at the same time as the former.

The fourth sort is also a native of both Indies, from whence I have received the seeds; this is an annual plant, which rises about two feet high, dividing into small branches, garnished with oval heart-shaped leaves, sawed on their edges. The flowers of this are very small, of a pale yellow, and are succeeded by swelling, rough, four-cornered seed-vessels, about an inch long, flattened at the top, where there are four horns, which are reflexed, so that these have some resemblance in shape to the Clove. This flowers and seeds about the same time as the former sorts.

The seeds of the fifth sort were sent me from Carthage in New Spain, where the plants grow naturally; this is an annual plant, which rises about three feet high, sending out several weak side branches, garnished with leaves about three inches long, and one broad in the middle, lessening gradually to both ends, and are indented on the edges like the teeth of a saw, sitting close to the branches. The flowers come out singly, opposite to the leaves; they are very small, of a pale yellow, and are succeeded by seed-vessels near two inches long, which are flat, and have two cells filled with small angular seeds. This flowers and ripens its seeds about the same time as the former.

The seeds of the sixth sort were sent me from Jamaica by the late Dr. Houstoun; this is an annual plant, which rises with a strong herbaceous stalk between three and four feet high, sending out several side branches, which grow erect, garnished with heart-shaped leaves sawed on their edges, standing upon long slender foot-stalks; between these grow many smaller leaves nearly of the same form, sitting close to the branches. The flowers come out from the side of the branches, on short foot-stalks; they are very small, of a pale yellow, and are succeeded

by flat seed-vessels near three inches long, ending in two horns; these open in two cells, which are filled with small angular seeds.

The seeds of the seventh sort were sent me from Barbadoes, where the plant grows naturally, for I have also had it rise in the earth which came over from thence in tubs with growing plants: this rises about the same height as the sixth, sending out several weak side branches, garnished with long narrow leaves, which are rough, and sawed on their edges, sitting close to the branches; between the larger leaves come out several small ones, which are placed irregularly on the branches. The flowers are small, of a pale yellow, and come out on the side of the branches opposite to the leaves; these are succeeded by very narrow compressed pods two inches long, opening with two valves, and filled with small angular seeds. It flowers and seeds at the same time with the former.

The eighth sort grows naturally in Jamaica; this rises with a shrubby stalk four feet high, dividing into a great number of small branches, which are closely garnished with small, oval, sawed leaves, sitting close to the branches; between these are many very small leaves, placed without order: the flowers are produced on the side of the branches on very short foot-stalks; these are small, and the petals soon fall off, so that it has been supposed to have no petals. The flowers are succeeded by compressed seed-vessels three inches long, which are rounded at their points, and open with two valves at the top, containing a great number of small angular seeds. This plant hath a perennial stalk, so may be preserved through the winter in a moderate stove, and the second year will flower in June, and produce ripe seeds in autumn; but when the plants are brought forward so as to flower the first year, they seldom perfect their seeds, and these plants cannot be so well preserved as those which are treated hardily in the summer.

All these sorts are too tender to thrive in England in the open air, therefore their seeds must be sown on a hot-bed in the spring; and when the plants are come up fit to remove, they should be transplanted on a fresh hot-bed to bring the plants forward, otherwise they will not ripen seeds. After the plants are rooted in the new hot-bed, they must have free air admitted to them every day, in proportion to the warmth of the season, for they must not be drawn up weak; when the plants have obtained strength, they should be transplanted each into a separate pot, and plunged into a hot-bed, observing to shade them from the sun till they have taken root; then they must have a large share of air every day, and should be frequently refreshed with water; and in June they should be gradually inured to the open air, and part of them may be shaken out of the pots, and planted in a warm border, where, if the season proves warm, they will flower and perfect their seeds; but as these will sometimes fail, it will be proper to put one or two plants of each sort into pots, which should be placed in a glass-case, where they may be screened from bad weather, and from these good seeds may always be obtained. The last sort may also be treated in the same manner during the summer season, but in autumn they must be removed into the stove, and plunged into the bark-bed, and these will flower early the second year, and ripen seeds.

C O R D I A. Plum. Nov. Gen. 13. tab. 14. Sebestena. Dillen. Hort. Elth. 225. Sebesten.

The CHARACTERS are,

The flower hath a permanent empalemt of one leaf, indented in three parts. It hath one funnel-shaped petal, whose tube is the length of the empalemt, and the top is divided into four, five, or six parts, which are obtuse and erect. It hath five awl-shaped stamina, terminated by long summits, and in the center a roundish pointed germen, supporting a bifid style, crowned by two obtuse stigmas. The germen afterward becomes a dry berry, which is globular and pointed, fastened to the empalemt, and incloses a furrowed nut with four cells.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. CORDIA (*Sebestina*) foliis oblongo-ovatis, repandis, scabris. Lin. Sp. Plant. 190. *Cordia with oblong, oval, rough leaves, turning backward.* Caryophyllus spurius inodorus, folio subrotundo, scabro, flore racemoso, hexapetaloides, coccineo. Sloan. Cat. 136. *Commonly called Lignum Aloes.*
2. CORDIA (*Myxa*) foliis tomentosis, corymbis lateralibus, calycibus decemstriatis. Lin. Sp. 273. *Cordia with oval woolly leaves, flowers growing in a corymbus from the side of the branches, and empalemts with ten stripes.* Sebestina domestica five Myxa. Com. Hort. Amst. 1. 139. *The cultivated Sebesten.*
3. CORDIA (*Macrophylla*) foliis ovatis, villosis sesquipedalibus. Lin. Sp. Plant. 274. *Cordia with oval woolly leaves half a foot long.* Prunus racemosa, foliis oblongis hirsutis maximis, fructu rubro. Sloan. Cat. Jam. 184.

The first sort grows naturally in several islands in the West-Indies: this rises with several shrubby stalks eight or nine feet high, which are garnished toward the top with oblong, oval, rough leaves, standing alternate on short foot-stalks; they are of a deep green on their upper side. The flowers terminate the branches, growing in large clusters upon branching foot-stalks, some sustaining one, others two, and some have three flowers, which are large, funnel-shaped, having long tubes, which spread open at the top, where it is divided into five obtuse segments; they are of a beautiful scarlet, so make a fine appearance.

The second sort is by most botanists believed to be the Myxa of Cæsalpinus, which is the best Sebesten of the shops; the fruit of which was formerly used in medicine, but of late years has been seldom brought to England, therefore is rarely ordered. This is called Assyrian Plum, from the country where it naturally grows. It rises to the height of our common Plum-trees, but was very rare in this country till the year 1762, when there was some of the fruit sent from Egypt, by those persons who were sent to travel at the king of Denmark's expence, from which fruit some plants have been raised in the Chelsea garden.

The third sort was discovered by father Plumier, in some of the French islands of America; and since was found in the bay of Campeachy, by Mr. Robert Millar, who sent the seeds to England: this sort grows to the height of eighteen or twenty feet in the natural places where it is found wild; it hath winged leaves, which are large, entire, and smooth; but it hath not as yet flowered in England, so I can give no farther account of it.

These plants, being natives of warm countries, are too tender to live through the winter in this country, unless they are preserved in a stove: they are all propagated by seeds, which must be procured from the countries of their natural growth; these seeds must be sown in small pots, which must be plunged into a good hot-bed of tanners bark in the spring; and if the seeds are fresh and good, the plants will begin to appear in six or eight weeks after. These must be brought forward in the hot-bed, by being treated as other tender exotic plants, observing frequently to water them in summer; and in July, if the plants have made much advance, they should be gradually hardened, otherwise they will grow so weak as not to be easily preserved through the winter. As these plants obtain strength, they will become more hardy; but during the two first winters, it will be proper to plunge them into the tan-bed in the stove; but when they begin to have woody stems, they may be placed on shelves, in a dry stove; where, if they are kept in a moderate degree of heat, they may be preserved very well (especially the first sort) which is somewhat hardier than the others. This may also be placed abroad in a warm situation, in the beginning of July, where

C O R

the plants may remain till the middle of September, provided the season continues warm, otherwise they must be removed into the stove sooner.

The first sort produces very fine flowers, of a scarlet colour, in large bunches, at the extremity of the branches, after the same manner as the Oleander or Rose-bay; but these flowers are much larger, and of a much finer colour.

A small piece of the wood of this tree being put on a pan of lighted coals, will send forth a most agreeable odour, and will perfume a whole house.

COREOPSIS. Lin. Gen. Pl. 879. Tickseed.

The CHARACTERS are,

The common empalement of the flower is double, the outer being composed of eight leaves, placed circularly; the inner is in every part larger, membranaceous, and coloured. The disk of the flower is composed of many hermaphrodite florets, which are tubular, and divided into five parts at the top; these have each five hairy stamina, terminated by cylindrical summits. In their center is situated a compressed germen with two horns, supporting a slender style, crowned by an acute bifid stigma. The germen afterward becomes a single orbicular seed, convex on one side, and hollow on the other, having a membranaceous border, and two horns on the top. The border or rays of the flower is composed of eight female florets which are large, and tongue-shaped, indented in five parts; these have no stamina, but a germen like the other, without any style or stigma, and are abortive.

This genus of plants is ranged in the third section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia Frustranea; the flowers of this class and section are composed of hermaphrodite florets which are fruitful, and female half florets which are barren.

The SPECIES are,

1. **COREOPSIS** (*Alternifolia*) foliis lanceolatis, serratis, alternis, petiolatis decurrentibus. Hort. Upsal. 270. *Tickseed with spear-shaped sawed leaves, placed alternate, and winged foot-stalks.* Chrysanthemum Virginianum, caule alato, ramosius, flore minore. Pluk. Alm. 100.
2. **COREOPSIS** (*Lanceolata*) foliis lanceolatis, integerrimis ciliatis. Lin. Sp. Plant. 1283. *Tickseed with spear-shaped leaves which are entire.* Bidens succisæ folio, radio amplo laciniato. Hort. Elth. 55.
3. **COREOPSIS** (*Verticillata*) foliis decomposito pinnatis, linearibus. Lin. Sp. Plant. 907. *Tickseed with decomposed, winged, narrow leaves.* Ceratocephalus delphinii foliis. Vaill. Act. 1720.
4. **COREOPSIS** (*Tripteris*) foliis subternatis, integerrimis. Hort. Upsal. 269. *Tickseed with leaves growing by threes, which are entire.* Chrysanthemum Virginianum, folio acutiore, lævi, trifoliato, sc. anagyridis folio. Mor. Hist. 3. p. 21.
5. **COREOPSIS** (*Radiata*) foliis lineari-lanceolatis, acutè serratis, oppositis radio amplo integro. *Tickseed with narrow spear-shaped leaves, which are opposite and sharply sawed, and the rays of the flower large and entire.*

The first sort grows naturally in North America every where. This hath a perennial root; the stalks decay to the root every winter, which are strong, herbaceous, and rise to the height of eight or ten feet, garnished with spear-shaped leaves sawed on their edges, from three to four inches long, and one broad in the middle, placed alternate on every side the stalks, having short foot-stalks, with a border or wing running from one to the other, the whole length of the stalk. The flowers grow at the top of the stalks, forming a sort of corymbus, each foot-stalk sustaining one, two, or three yellow flowers, shaped like Sun-flowers, but much smaller. This flowers in September and October, but doth not produce seeds in England. It is a very hardy plant, and may be propagated in plenty by parting the roots. The best time for this is in autumn, when the stalks begin to decay. It will thrive in almost every soil and situation.

The second sort is an annual plant. The seeds of this were brought me from Carolina by Mr. Catesby, in the year 1726. This hath an upright stalk, garnished with smooth, narrow, spear-shaped leaves, placed

C O R

opposite, which are entire; from the wings of the leaves come out the foot-stalks of the flowers, by pairs opposite, and stand erect; the lower part of these have one or two pair of very narrow leaves, but the upper is naked, and terminated by one large yellow flower, whose border or rays are deeply cut into several segments; these are succeeded by flat winged seeds, which, when ripe, roll up; the naked foot-stalks of these flowers are more than a foot long. This must be sown upon a gentle hot-bed in the spring, and when the plants are fit to transplant, they should be each planted into a separate small pot, and plunged into a fresh hot-bed to bring them forward; and in June they should be inured by degrees to the open air, and afterward some of them may be shaken out of the pots, and planted in a warm border; where, if the season is good, they will flower in the middle of July, and ripen their seeds the beginning of September.

The third sort hath a perennial root, sending up many stiff angular stalks, which rise upward of three feet high, garnished at each joint with decomposed winged leaves, standing opposite; these are very narrow and entire. The branches also come out by pairs opposite, as do also the foot-stalks of the flowers; these are long, slender, and each terminated by a single flower, of a bright yellow colour, the rays or border being oval and entire. The disk or middle is of a dark purple colour. These appear in July, and continue till September, during which time they make a fine appearance. This grows naturally in Maryland and Philadelphia. It is propagated by parting the roots, in the same manner as the first sort, and delights in a light loamy earth, and sunny exposure.

The fourth sort hath a perennial root. It grows naturally in many parts of North America, but has been long cultivated in the English gardens; the stalks of this are strong, round, and smooth, rising six or seven feet high, garnished at each joint with some trifoliate leaves, which stand opposite. The flowers are produced in bunches at the top of the stalks, standing upon long foot-stalks; they are of a pale yellow, with a dark purple disk. It flowers in July, but seldom produces good seeds in England. This sort is propagated by parting the roots in the same manner as the first, but requires a better soil and position.

The fifth sort grows naturally in South Carolina, from whence the seeds were sent me by the late Dr. Dale. This is an annual plant, which rises with upright stalks to the height of four feet, garnished with narrow spear-shaped leaves, ending in long points, and are deeply sawed on their edges, standing opposite at each joint, upon short foot-stalks; these leaves are from three to four inches long, and three quarters of an inch broad in the middle, of a deep green on their upper side, and pale on their under. At all the upper joints of the stalks come out two long slender foot-stalks, one on each side, which are garnished with two or three pair of small leaves, and terminated by one flower, composed of seven female half florets, which compose the ray; these are oval and entire. The disk is composed of a great number of hermaphrodite florets, which are of a dark colour, and the summits of the stamina are of a bright yellow; these hermaphrodite florets are each succeeded by one flat bordered seed, having two horns or teeth. This sort flowers in August, and if the autumn proves favourable, will ripen its seeds in October; but in cold seasons it will not perfect seeds in England.

This is propagated by seeds, which should be sown on a warm border in autumn, and the plants will come up the following spring; for if the seeds are sown in the spring, the plants seldom rise till the year after. When the plants are fit to remove, they should be carefully taken up, and either planted where they are designed to remain, or into a nursery-bed, at four inches distance, to get strength, observing to shade them from the sun till they have taken fresh root; after

after which, those which are planted out for good, will require no other treatment but to keep them clean from weeds; and as they advance in height, they should be supported by sticks, otherwise the strong winds in autumn often break them; and those which were placed in a nursery-bed, when they have obtained proper strength, should be taken up and transplanted with balls of earth to their roots, where they are designed to stand for flowering.

As these plants continue to produce flowers till the frost puts a stop to them, they merit a place in every curious garden, especially those which do not ramble and spread too much. The first is the least deserving of either, so is seldom preserved, but in botanic gardens for the sake of variety.

CORIANDRUM. Lin. Gen. Plant. 318. Tourn. Inst. R. H. 316. tab. 168. [of *Κορίανδρον*, of *Κόρις*, Gr. a tick; so called, either because it has the scent of this insect, or, as others say, because it drives away or kills them; and *Ἀνδρο*, Gr. the isle where it grew plentifully.] Coriander.

The CHARACTERS are,

It is a plant with an umbellated flower; the universal umbel hath but few rays, the partial umbels have many. The first hath no involucre, but the latter hath a three-leaved one; the proper empalement is divided into five parts; the rays of the principal umbel are difform. The hermaphrodite flowers which form the disk, have five equal heart-shaped petals, which are inflexed, but those of the rays have five unequal petals of the same form; they have each five stamina, terminated by roundish summits. The germen which is situated under the flower, supports two styles, crowned by small radiated stigmas; the germen afterward becomes a spherical fruit, divided into two parts, each having a hemispherical concave seed.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. **CORIANDRUM** (*Sativum*) fructibus globosis. Hort. Cliff. 100. *Coriander with globular fruit.* *Coriandrum majus.* C. B. P. 158. *Greater Coriander.*
2. **CORIANDRUM** (*Testiculatum*) fructibus didymis. Hort. Cliff. 100. *Coriander with twin fruit.* *Coriandrum minus testiculatum.* C. B. P. 158.

The first of these species is the most common kind, which is cultivated in the European gardens and fields for the seeds, which are used in medicine. The second sort is less common than the first, and is seldom found but in botanic gardens in these parts of Europe. These plants grow naturally in the south of France, Spain, and Italy; but the first sort has been long cultivated in the gardens and fields, though at present there is not near so much of it sown in England as was some years past.

These plants are propagated by sowing their seeds in the autumn, in an open situation, on a bed of good fresh earth; and when the plants are come up, they should be hoed out to about four inches distance every way, clearing them from weeds; by which management these plants will grow strong, and produce a greater quantity of good seeds. The first sort was formerly cultivated in the gardens as a salad herb, and in the East-Indies is still much cultivated; for the plant is of great use in most of their compound dishes, as a culinary herb, and the seeds are also much esteemed for the like purposes; but in Europe neither of them are now much used.

The second sort will rise easily from seeds, if they are sown in the autumn; but those which are sown in the spring rarely succeed, or at least do not come up till the following spring.

CORIARIA. Lin. Gen. Plant. 458. Nissol. Act. Reg. 1711. *Myrtle-leaved Sumach, vulgò.*

The CHARACTERS are,

It is male and hermaphrodite in different plants; the male flowers have a five-leaved empalement; the flower has five leaves, which are joined to the empalement; these have ten slender stamina, terminated by oblong summits; the hermaphrodite flowers have the like empalement, and

the same number of petals, and in the center are placed five pointals, which turn to a berry, inclosing five kidney-shaped seeds.

This is ranged in the ninth section of Linnæus's twenty-second class, intitled Dioecia Decandria, the plants having male and hermaphrodite flowers on different roots.

The SPECIES are,

1. **CORIARIA** (*Myrtifolia*) foliis ovato oblongis. Hort. Upsal. 299. *Myrtle-leaved Sumach, with oblong oval leaves.* *Coriaria vulgaris mas.* Nissol. Act. 1711.
2. **CORIARIA** (*Femina*) vulgaris foemina. Lin. Hort. Cliff. *Female Myrtle-leaved Sumach.*

The sort with male flowers has been the most common in England, the other having been very rarely raised in our gardens: a few years past, when some plants were raised from seeds, which came from Italy, in the Chelsea garden, where the plants so raised have most of them proved of the hermaphrodite sort, and have produced great quantities of seeds, which have grown, though there is not one plant of the male sort at present in the garden; the not finding any plants in the English gardens, but those with male flowers, occasioned my writing abroad for the seeds. These grow wild in great plenty about Montpellier in France, where it is used for tanning of leather; and, from this use, has been titled by the botanists, *Rhus coriariorum*, i. e. Tanners Sumach.

These shrubs seldom grow more than three or four feet high; and as they creep at the root, they send forth many stems, whereby they form a thicket, so may be planted to fill up vacancies in wilderness quarters; but they are improper for small gardens, where they will take up too much room; and as there is no great beauty in the flowers, they are only admitted for variety.

It is strange that Monsieur Nissol, who lived upon the place where these grew in plenty, who constituted this genus, in the Memoirs of the Academy at Paris, has taken no notice of their being male and hermaphrodite in different plants.

It may be propagated plentifully from the suckers, which are produced from the creeping roots in great abundance; these should be taken off in March, and planted into a nursery to form good roots, where they may continue one or two years, and then must be removed to the places where they are to remain.

This plant delights in a loamy soil which is not too stiff, and should be placed where it may have shelter from the north and east winds; where it will endure the cold of our ordinary winters very well, and will flower better than if it is preserved in pots and sheltered in the winter, as hath been by some practised.

CORINDUM. See **CARDIOSPERMUM.**

CORIS. Lin. Gen. Plant. 216. Tourn. Inst. 652. tab. 423. We have no English name for this plant.

The CHARACTERS are,

The empalement of the flower is of one leaf, with a swelling belly, but closed at the top, where it is divided into five parts, which are crowned by five spines; the flower hath one irregular petal, whose tube is the length of the empalement, and spread open at the top, where it is divided into five oblong segments, which are obtuse and indented; it hath five bristly stamina, terminated by single summits. In the center is situated a round germen, supporting a slender declining style, crowned by a thick stigma; the empalement afterward becomes a globular capsule, having five valves, inclosing several small oval seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

We have but one SPECIES of this plant, viz.

CORIS (*Monspeliensis*). Hort. Cliff. 68. *Coris cærulea maritima.* C. B. P. 280. *Blue maritime Coris.*

There are two other varieties of this plant, one with a red, and the other a white flower, but these are only accidental varieties arising from the same seeds.

These plants grow wild about Montpellier, and in many other parts of the south of France, and also in Italy; they seldom grow above six inches high, and spread

spread near the surface of the ground like heath; and in June, when they are full of flowers, they make a very pretty appearance.

They may be propagated by sowing their seeds in the spring, on a bed of fresh earth; and when the plants are about an inch high, they should be transplanted, some of them into pots filled with fresh light earth, that they may be sheltered in winter; and the others into a warm border, where they will endure the cold of our ordinary winters very well, but in severe frost they are generally destroyed; for which reason, it will be proper to have some plants of each sort in pots, which may be put under a common hot-bed frame in winter, where they may be covered in frosty weather; but when it is mild, they should have a great share of free air: these plants sometimes produce ripe seeds in England; but as they do not constantly perfect their seeds, it will be proper to increase them from slips and cuttings, which will take root, if planted about the end of August on a very gentle hot-bed, and shaded from the sun and duly watered.

CORISPERMUM. Lin. Gen. Plant. 12. Juss. Act. R. S. 1712. Tickseed.

The CHARACTERS are,

The flower hath no empalement, it hath two compressed incurved petals, which stand opposite and are equal; it hath one, two, or three stamina, which are shorter than the petals, terminated by single summits, with a compressed pointed germen, supporting two hairy styles, crowned by acute stigmas. The germen afterward becomes one oval compressed seed, with an acute border.

This genus of plants is ranged in the second section of Linnæus's first class, intitled Monandria Digynia, the flower having one stamina and two styles.

The SPECIES are,

1. **CORISPERMUM** (*Hyssopifolium*) floribus lateralibus Hort. Upsal. 2. *Tickseed with flowers on the side of the stalks.* Corispermum Hyssopifolium. Juss. Act. R. S. 1712. *Hyssop-leaved Tickseed.*

2. **CORISPERMUM** (*Squarrosum*) spicis squarrosis. Hort. Upsal. 3. *Tickseed with rough spikes.* Rhagrostis foliis arundinaceis. Buxb. Cent. 3. p. 30. *Rhagrostis with Reed-like leaves.*

These plants are preserved in botanic gardens for the sake of variety; but as they have no beauty, are seldom cultivated in other gardens.

The first sort is an annual plant, which, if suffered to scatter its seeds, the ground will be plentifully stocked with the plants, which will require no other care but to prevent the weeds from over-growing them.

The second will not grow but in marshy places, where there is standing water; over the surface of which this plant will soon extend, when once it is established.

As we had no English name to this genus, I have given it this of Tickseed, which corresponds with the Greek name.

CORK-TREE. See QUERCUS.

CORN-FLAG. See GLADIOLUS.

CORNICULATE PLANTS [Plantæ Corniculatæ,] are such, as after each flower, produce many horned seed-pods, called Siliquæ.

CORN-MARIGOLD. See CHRYSANTHEMUM.

CORN-SALLAD. See VALERIANA.

CORNUS. Lin. Gen. Plant. 139. Tourn. Inst. 641. tab. 410. [so called, of Cornu, Lat. a horn; because its wood, or the shell of its fruit, is hard as a horn.] The Cornelian Cherry.

The CHARACTERS are,

It hath many flowers included in one common four-leaved involucre, which is coloured. The flowers have each a small empalement, sitting on the germen, which is indented in four parts. They have four plain petals, which are smaller than the leaves of the involucre, and four erect stamina, which are longer than the petals, terminated by roundish summits. The round germen situated below the empalement, supports a slender style, crowned by an obtuse stigma. The germen afterward becomes an oval, or roundish berry, inclosing a nut, with two cells, having an oblong kernel.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flowers having four stamina and but one style.

The SPECIES are,

1. **CORNUS** (*Sanguinea*) arborea, cymis nudis. It. Westgoth. Lin. Sp. Plant. 117. *Dogwood-tree with naked shoots.* Cornus foemina. C. B. P. 447. *Female Dogwood, and the Virga Sanguinea.* Matth.

2. **CORNUS** (*Mas*) arborea, umbellis involucre æquantibus. Hort. Cliff. 38. *Tree Dogwood with umbels equal to the involucre.* Cornus hortensis mas. C. B. P. 447. *Male Cornel, or Cornelian Cherry-tree.*

3. **CORNUS** (*Florida*) arborea, involucre maximo, foliis obversè cordatis. Hort. Cliff. 38. *Tree Dogwood with a very large involucre, and obverse heart-shaped leaves.* Cornus mas, Virginiana, flosculis in corymbis digestis, à perianthio tetrapetalo albo radiatim cinctis. Pluk. Alm. 120.

4. **CORNUS** (*Fœmina*) arborea, foliis lanceolatis, acutis, nervosis, floribus corymbosis terminalibus. *Tree Dogwood with spear-shaped acute leaves which are veined, and flowers disposed in a corymbus, terminating the branches.* Cornus foemina Virginiana angustiore folio. Edit. prior. *Female Virginia Dogwood with a narrower leaf.*

5. **CORNUS** (*Amomum*) arborea foliis ovatis petiolatis, floribus corymbosis terminalibus. *Tree Dogwood with oval leaves having foot-stalks, and flowers collected into a corymbus at the end of the branches.* Cornus Americana sylvestris, domesticæ similis, baccâ cærulei coloris elegantissimâ, Amomum Novæ Angliæ quorundam. Pluk. Phyt. tab. 169. f. 3. *By some supposed to be the true Amomum of New England.*

6. **CORNUS** (*Candidissima*) arborea foliis lanceolatis, acutis, glabris, umbellis involucre minoribus, baccis ovatis. *Tree Dogwood with smooth, spear-shaped, pointed leaves, umbels smaller than the involucre, and oval berries.* Cornus foemina candidissimis foliis Americana. Pluk. Alm. 120.

7. **CORNUS** (*Tartarica*) arborea foliis oblongo ovatis, nervosis, infernè albis, floribus corymbosis terminalibus. *Tree Dogwood with oblong, oval, veined leaves, white on their under side, and flowers growing in a corymbus at the end of the branches.* Cornus sylvestris fructu albo. Amman. Ruth. *Wild Dogwood with a white fruit.*

8. **CORNUS** (*Suecica*) herbacea ramis binis. Fl. Lapp. 55. *Herbaceous Dogwood with double branches.* Cornus pumila herbacea, chamæpericlymenum dicta. Hort. Elth. 108. *Low herbaceous Dogwood, called Dwarf Honeyfuckle.*

The first of these trees is very common in the hedges in divers parts of England, and is seldom preserved in gardens. The fruit of this plant is often brought into the markets, and sold for Buckthorn berries, from which it may be easily distinguished, if the berries are opened to observe how many stones there are in each; which in this fruit is but one, but in the Buckthorn four, and they may be easily distinguished by rubbing the juice of the berries on paper; that of the Buckthorn will stain the paper green, whereas the juice of this stains it purple. This tree is called Virga Sanguinea, from the young shoots being of a fine red colour. There is a variety of this tree with variegated leaves, which is preserved in the nurseries, but is not much esteemed.

The second sort is very common in the English gardens, where it was formerly propagated for its fruit, which was by some people preserved to make tarts. It is also used in medicine as an astringent and cooler: there is also an officinal preparation of this fruit, called Rob de Cornis. Of this there are two or three varieties, which differ only in the colour of their fruit, but that with the red fruit is the most common in England.

As the fruit of this tree is not at present much esteemed, the nursery-men about London propagate it as one of the sorts which is commonly sold as a flowering shrub, and is by some people valued for coming so early to flower; for if the season is mild, the

flowers will appear by the beginning of February; and though there is no great beauty in the flowers, yet, as they are generally produced in plenty, at a season when few other flowers appear upon trees, a few plants of them may be admitted for variety. The fruit of this tree is seldom ripe before September. The tree will grow eighteen or twenty feet high, and make a large head.

The third sort is an American, from whence the seeds have been brought to England: this is found in all northern parts of America, as are also the fourth, fifth, and sixth sorts, being natives of the woods in Virginia, New England, Maryland, and Carolina. These are all of them very hardy, and thrive well in the open air in England, so are cultivated by the nursery-men near London, to add to the variety of their hardy trees: these grow to the same height with our common female Dogberry, and make a much better appearance. The shoots of the fifth sort are of a beautiful red colour in winter; and in summer the leaves being large, of a whitish colour on their under side, and the bunches of white flowers growing at the extremity of every branch, renders this shrub valuable; and in autumn, when the large bunches of blue berries are ripe, they make a fine appearance.

The third sort is now very common in the nurseries, where it is known by the name of Virginia Dogwood. This sort is of much humbler growth than either of the former, seldom rising above seven or eight feet high, but is generally well garnished with leaves, which are larger than either of the other sorts. This does not flower so plentifully as the other sorts, nor have I yet seen any of these shrubs, which have produced berries in England, though they are as hardy as the other.

There is a variety of this with a red involucre or cover to the flowers, which adds to the beauty of the plant; this was found wild in Virginia by Mr. Banister, and afterward by Mr. Catesby. This and the former sort are great ornaments to the woods in America, first by their early flowering in the spring before the green leaves appear; and in the winter they are also beautiful when the berries are ripe, which hang upon the shrubs till the spring.

The eighth sort grows upon Cheviot-hills in Northumberland, and also upon the Alps, and other mountainous places in the northern countries, but is very difficult to preserve in gardens; the only method is, to remove the plants from the places of their natural growth, with good balls of earth to their roots, and plant them in a moist shady situation, where they are not annoyed by the roots of other plants. In such a situation they may be preserved two or three years, but it rarely happens that they will continue much longer. This is a low herbaceous plant, whose stalks decay in the autumn.

All the sorts of Dogwood may be propagated by their seeds, which, if sown in autumn soon after they are ripe, will most of them come up the following spring; but if the seeds are not sown in autumn, they will lie a year in the ground before the plants will appear, and when the year proves dry, they will sometimes remain two years in the ground; therefore the place should not be disturbed, where these seeds are sown, under two years, if the plants should not come up sooner. When the plants are come up, they should be duly watered in dry weather, and kept clean from weeds; and the autumn following they may be removed, and planted in beds in the nursery, where they may remain two years, by which time they will be fit to transplant where they are to remain for good. They are also propagated by suckers, and laying down the branches. Most of the sorts produce plenty of suckers, especially when they are planted on a moist light soil, which may be taken off from the old plants in autumn, and planted into a nursery for a year or two, and then may be transplanted into the places where they are to remain; but those plants which are propagated by suckers, rarely have so good roots as those which are propagated by layers; and

being much more inclinable to shoot out suckers, whereby they will fill the ground round them with their spawn, they are not near so valuable as those plants which are raised from layers.

CORNUTIA. Plum. Nov. Gen. 17. Lin. Gen. Plant. 684. Agnanthus. Vaill. Act. R. 1722. We have no English name for this plant. It is so called from Cornutus, a physician of Paris, who published a history of Canada plants.

The CHARACTERS are,

The flower hath a small permanent empalement of one leaf, which is tubular, and indented in five parts at the top. The flower is of one petal, having a cylindrical tube, which is much longer than the empalement, and divided into four parts at the top; the upper segment is round and erect, the two side ones spread apart, and the lower is round and entire. It hath four stamina; two of these are longer than the tube, the other are shorter; they are terminated by inclining summits. In the center is situated the roundish germen, supporting a long style, divided into two parts, crowned by two thick stigmas. The germen afterward becomes a globular berry, sitting upon the empalement, inclosing several kidney-shaped seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flowers having two long and two short stamina, and the seeds are included in a capsule.

There is but one SPECIES of this genus, viz.

CORNUTIA (Pyramidata). Hort. Cliff. 319. Cornutia flore pyramidata cæruleo, foliis incanis. Nov. Gen. 32. Cornutia with a blue pyramidal flower and hoary leaves.

This plant was first discovered by father Plumier in America, who gave it the name. It is found in plenty in several of the islands in the West-Indies, as also at Campeachy and La Vera Cruz, from both which places I received the seeds, which were collected by my late ingenious friend Dr. William Houstoun, and afterward by Mr. Robert Millar, from the same country. It grows to the height of ten or twelve feet; the branches are four-cornered, grow straggling, and the leaves are placed opposite. The flowers are produced in spikes at the end of the branches, which are of a fine blue colour; these usually appear in autumn, and sometimes will remain in beauty for two months or more.

It is propagated by seeds, which should be sown early in the spring on a hot-bed; and when the plants are come up, they should be transplanted each into a separate halfpenny pot, filled with light fresh earth, and plunged into a hot-bed of tanners bark, observing to shade them until they have taken root; after which they should have fresh air let into the bed, in proportion to the warmth of the season, and should be frequently watered (for it naturally grows on swampy soils.) When the plants have filled these pots with their roots, they should be shifted into others of a larger size, and plunged into a hot-bed again, where they should be continued till October, when they must be removed into the bark-stove, and plunged into the tan, for otherwise it will be very difficult to preserve them through the winter. The stove in which these plants are placed should be kept to the temperate heat marked on Mr. Fowler's thermometers, which will agree better with them than a hotter stove. The third year from seeds these plants will flower, when they make a fine appearance in the stove, but they never perfect their seeds in England.

They may also be propagated by cuttings, which, if planted into pots filled with earth, and plunged into a bark-bed, observing to shade and water them, will take root, and must be afterwards treated as the seedling plants.

CORONA IMPERIALIS. See FRITILLARIA.

CORONA SOLIS. See HELIANTHUS.

CORONILLA, Jointed-podded Colutea.

The CHARACTERS are,

The flower hath a short permanent empalement of one leaf, which is compressed, bifid, and erect. It hath a butterfly

butterfly flower, whose standard is heart-shaped, and reflexed on each side. The wings are oval, and join at the top. The keel is shorter than the wings, is pointed and compressed. It hath nine stamina which are united, and one standing single, which are broad at the top, terminated by small summits. In the center is situated an oblong taper germen, supporting a bristly rising style, crowned by an obtuse stigma. The germen afterward becomes a taper jointed pod, inclosing oblong seeds.

This genus of plants is ranged in the second section of Linnæus's seventeenth class, intitled Diadelphia Decandria, the flower having ten stamina, nine of which are united, and one stands single. To this genus Dr. Linnæus has joined the Emerus of Cæsalpinus, and the Securidaca of Tournefort, whereby he multiplies the species; but as these differ essentially in their fructification, I shall treat of them separately, following the example of all the former botanists.

The SPECIES are,

1. CORONILLA (*Glaucæ*) fruticosa, foliis septenis, stipulis lanceolatis. Lin. Sp. 1047. *Shrubby Coronilla with seven pair of small leaves, and spear-shaped stipula.* Coronilla maritima glauco folio. Tourn. Inst. 650.
2. CORONILLA (*Argentea*) fruticosa foliolis undenis, extimo majore. Lin. Sp. Plant. 1049. *Shrubby Coronilla with eleven pair of small leaves, the outer being the largest.* Coronilla argentea Cretica. Tourn. Inst. 650.
3. CORONILLA (*Valentina*) fruticosa foliis subnoventis suborbiculatis. Lin. Sp. Plant. 1047. *Shrubby Coronilla with nine lobes which are orbicular.* Polygala Valentina.
4. CORONILLA (*Hispanica*) fruticosa enneaphylla, foliolis emarginatis, stipulis majoribus subrotundis. *Shrubby nine-leaved Coronilla, whose small leaves are indented, and larger roundish stipulae.* Coronilla filiquis & seminibus crassioribus. Tourn. Inst. R. H. 650.
5. CORONILLA (*Minima*) foliolis plurimis, ovatis, caule suffruticoso declinato, pedunculis longioribus. *Coronilla with many oval lobes, a declining stalk somewhat shrubby, and longer foot-stalks to the flowers.* Coronilla minima. Tourn. Inst. R. H. 650. *Smallest Coronilla.*
6. CORONILLA (*Varia*) herbacea, leguminibus erectis, teretibus, torosis, numerosis, foliis glabris. Hort. Cliff. 363. *Herbaceous Coronilla with many taper erect pods, and smooth leaves.* Coronilla herbacea flore vario. Tourn. Inst. 650.
7. CORONILLA (*Cretica*) herbacea, leguminibus quinis, erectis, teretibus, articulatis. Prod. Leyd. 387. *Herbaceous Coronilla with five taper, erect, jointed pods.* Coronilla Cretica herbacea, flore parvo purpurascente. Tourn. Cor. 44.
8. CORONILLA (*Orientalis*) herbacea leguminibus numerosis, radiatis, crassioribus, articulatis, foliolis subtus glaucis. *Herbaceous Coronilla with many thick jointed pods disposed like rays, and smaller leaves of a sea-green on their under side.* Coronilla orientalis herbacea, flore magno luteo. Tourn. Cor. 44.
9. CORONILLA (*Juncea*) fruticosa, foliis quinq; ternatisque lineari-lanceolatis subcarnosis obtusis. Lin. Sp. 1047. *Shrubby Coronilla with five and trefoil linear, spear-shaped leaves, which are obtuse and fleshy.* Doricum luteum Hispanicum carnosius. Barrel. Icon. 133.
10. CORONILLA (*Scandens*) caule hirsuto, volubili, foliolis quinque ovatis, floribus binis, erectis, axillaribus, leguminibus erectis, villosis. *Coronilla with a twining hairy stalk, five oval leaves, two flowers growing erect on the sides of the branches, and upright hairy pods.* Coronilla scandens pentaphylla. Plum. Cat. 19. *Climbing five-leaved Coronilla.*

The first sort is an humble shrub, which seldom rises more than two or three feet high, with a ligneous branching stalk, garnished closely with winged leaves, each being generally composed of five pair of small leaves (or lobes) terminated by an odd one; these are narrow at their base, and broad at the top; where they are roundish and indented; they are of a sea-

green colour, and continue all the year. The flowers are produced on slender foot-stalks from the wings of the leaves, on the upper part of the branches; several standing together in a roundish bunch; they are of the butterfly, or Pea-bloom kind, and of a bright yellow colour, having a very strong odour, which to some persons is agreeable, but to others the contrary. This flowers in April and May; and the seeds ripen in August.

This plant is propagated by sowing the seeds in the spring, either upon a gentle hot-bed, or on a warm border of light fresh earth; and when the plants are come up about two inches high, they should be transplanted either into pots, or a bed of good rich earth, at about four or five inches distance every way, where they may remain until they have obtained strength enough to plant out for good; which should be either into pots filled with good fresh earth; or a warm situated border; in which, if the winter is not too severe, they will abide very well, provided they are in a dry soil.

The second sort is a shrub of the same size with the first, from which it differs in the number of small leaves (or lobes) on each midrib; these having nine or eleven, and are of a silver colour, but the flowers and pods are the same. It flowers at the same time; and requires the same treatment as the former.

The third sort is a shrubby plant, rising four or five feet high; the stalks are shrubby garnished with winged leaves, composed of many small oval lobes along the midrib by pairs, and ending in an odd one. The flowers stand upon long foot-stalks; which arise from the side of the branches; they are yellow, and grow together in close bunches. This flowers in winter and spring, and the seeds are ripe in August.

This is a perennial shrubby plant, which is propagated by seeds; they may be sown on a bed of light earth in April, and when the plants are fit to transplant, some of them should be planted in a warm border, close to a warm wall or pale, to which the branches should be trained; observing to shade them from the sun till they have taken fresh root, and also to refresh them with water when they require it. After they are well rooted, they will require no other culture but to keep them clean from weeds, and fasten their branches to the wall; the next year they will flower, and if they are on a dry soil and in a warm situation, they will continue many years. Some of these plants should be put into pots, that they may be removed into shelter in winter; where, if they are not too tenderly treated, they will flower great part of that season; but these will rarely produce seeds, whereas those in the full ground generally do, provided they are covered with mats in frosty weather.

The fourth sort is nearly like the first, but hath fewer pinnæ on each midrib. The flowers are larger, and have little scent. The pods and seeds are much larger, and the plants are not quite so hardy. This flowers in May and June, but rarely perfects seeds in England; it requires the same treatment as the first, but in winter the plants should be sheltered, otherwise hard frosts will destroy them.

The fifth sort is a low trailing plant with shrubby stalks, which spread near the ground, garnished with winged leaves, composed of many pair of small lobes placed along the midrib, terminated by an odd one; these are oval, and of a bright green; the flowers stand upon long foot-stalks in close bunches, they are yellow, and without scent. It flowers in May, and the seeds ripen in autumn. This is propagated by seeds in the same manner as the third; and requires the same treatment.

The sixth sort dies down every winter, but rises again the succeeding spring; the stalks of this rise to the height of five or six feet, where they have support; otherwise they trail on the ground, and are garnished with winged leaves, composed of several oblong small pinnæ, which are sometimes placed by pairs, and at other times are alternate, ending in a single one, they

are

are of a deep green. The flowers come out on long foot-stalks from the wings of the leaves, many growing together in round bunches; they are variable from a deep to a light purple, mixed with white, and are succeeded by slender pods from two to three inches long, standing erect. This plant flowers in June, July, and August, and the seeds ripen in autumn. The roots of this plant creep very far under ground, by which the plant increases greatly; which, when permitted to remain unremoved for two or three years, will spread and overbear what plants grow near it; for which reason the roots should be confined, and it should be planted at a distance from any other plants; it will grow in almost any soil and situation, but thrives best in a warm sunny exposure, in which the flowers will also be much fairer, and in greater quantities. This plant was formerly cultivated to feed cattle.

The seventh sort hath an herbaceous stalk, which rises two feet high, garnished with winged leaves, composed of six pair of small leaves, placed along the midrib, which is terminated by an odd one; these are larger than those of the sixth sort, and broader at the top. The foot-stalks of the flowers come out from the side of the stalks, but they are shorter than those of the sixth sort, and sustain smaller heads of flowers, which are succeeded by five taper jointed pods, near two inches long.

This is an annual plant, which grows naturally in the Archipelago, from whence Tournefort sent the seeds to the royal garden at Paris. The seeds of this sort should be sown on a bed of light earth in the spring, where the plants are designed to remain, and when the plants come up, they should be thinned where they are too close, and afterward kept clean from weeds, which is all the culture they will require. In June they will flower, and the seeds ripen in autumn.

The eighth sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the royal garden at Paris; this hath a perennial root, and an annual stalk, which rises upward of two feet high, standing erect. The leaves are composed of five or six pair of small oblong leaves, ranged along the midrib, which is terminated by an odd one. The foot-stalks of the flowers are strong, and upward of six inches in length, supporting large bunches of yellow flowers, which are succeeded by short thick pods about an inch long. This flowers in June and July, and in warm seasons the seeds will ripen in autumn: there is a variety of this with large white flowers.

This sort is propagated by seeds, which should be sown on a warm border of light earth in the spring; and when the plants come up, they must be carefully cleaned from weeds; when they are fit to remove, they should be transplanted into a warm border, where they are to remain, shading them from the sun till they have taken fresh root, after which they will require no farther care in summer, but to keep them clean from weeds; and in autumn, when the stalks are decayed, if the surface of the ground is covered with some old tan to keep out the frost, it will be a secure method to preserve the roots. The second year the plants will flower, and, if the same care is taken in winter, the roots may be continued some years.

The ninth sort grows naturally in Spain; this rises from two to four feet high, having many slender ligneous branches, garnished with narrow spear-shaped leaves, which are sometimes trifoliate, and at other times have five lobes on each foot-stalk; the flowers stand upon pretty long foot-stalks, which come out from the wings of the stalk, and are collected in small bunches; they are of a bright yellow colour, and appear for six or seven months together, but have not been succeeded by seeds here as yet.

This is propagated by seeds in the same manner as the first sort, and some of the plants should be planted in pots that they may be sheltered under a common

frame in winter, because in hard frosts the plants are often destroyed; but in mild weather they should be exposed to the air, otherwise they will draw up weak.

The tenth sort was discovered by father Plumier in America. I received the seeds of this plant from Carthagena, which were sent me by my late ingenious friend Dr. William Houstoun; this hath a slender, hairy, twining stalk, of a brown colour, twisting round any of the shrubs which stand near it, whereby it rises eight or ten feet high, and is garnished with winged leaves, for the most part composed of five oval lobes, one inch long, and half an inch broad, of a deep green. The flowers come out by pairs at each joint, standing on very short separate foot-stalks erect; they are large, and of a pale yellow; these are succeeded by taper jointed pods, more than three inches long, which are covered with short, soft, white, hairy down, and stand erect. This plant is propagated by seeds, which should be sown early in the spring on a moderate hot-bed; and when the plants are come up, they should be each transplanted into a halfpenny pot filled with fresh rich earth, and plunged into a hot-bed of tanners bark, observing to shade them until they have taken root; after which time they should have air and water in proportion to the warmth of the season, and when they have filled these pots with their roots, they should be shifted into pots of a larger size, and plunged into the hot-bed again, where they must remain until autumn, when they should be removed into the stove, and plunged into the tan. These plants must be constantly kept in the bark-stove, and placed among plants which require a moderate heat; where they will thrive and flower, and should be supported by tall sticks, round which they will twine as Hops do; for if they have not this support, they will twist round other plants and spoil them. These are very proper plants to place against an espalier on the back part of the stove, amongst other climbing plants, where they will make an agreeable variety.

If the plants are carefully managed in the winter, they may be preserved two or three years, and will annually flower in July, and sometimes they will produce ripe seeds in England.

CORONOPUS. See PLANTAGO.

CORTUSA. Lin. Gen. Plant. 181. [This plant is so called from Cortusus, a famous botanist, who first brought it into use.] Bears-ear Sanicle.

The CHARACTERS are,

The flower hath a small, spreading, permanent empalement, which is indented at the brim in five parts; this hath one wheel-shaped petal, spreading open to the bottom, and cut into five parts at the brim, having five prominent tubercles at the base. It hath five short obtuse stamina, which are terminated by oblong erect summits. In the center is situated an oval germen, supporting a slender style, crowned by a single stigma. The germen afterward becomes an oval, oblong, pointed capsule, having two longitudinal furrows, and one cell, opening with two valves, filled with small oblong seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. **CORTUSA (Matthioli)** calycibus corollâ brevioribus. Lin. Sp. Plant. 144. Bears Ear Sanicle, with an empalement shorter than the petal. Cortusa Matthioli. Clus. Hist. 1. p. 307. Bears Ear Sanicle of Matthioli.

2. **CORTUSA (Gmelini)** calycibus corollum excedentibus. Amoen. Acad. 2. p. 340. Bears Ear Sanicle with an empalement longer than the petal.

The first sort grows naturally on the Alps, and also on the mountains in Austria, and in Siberia. This plant sends out many oblong smooth leaves, which are a little indented on the edges, and form a sort of head, like the Auricula. The foot-stalks of the flowers come out in the center of the leaves; these rise about four inches high, and support an umbel of flowers, each sitting on a slender, separate, short foot-stalk;

stalk; they are of a flesh colour, and spread open like those of the Auricula. It flowers in April, but doth not produce seeds in the gardens, for this plant is with great difficulty kept in a garden. The only method by which I could ever preserve it, has been by planting the plants in pots, and placing them in a shady situation, where they were duly watered in dry weather; in this place they constantly remained both summer and winter, for the cold will not destroy them; the earth for this plant should be light, and not too rich, for dung is very injurious to it. As this very rarely produces any seeds in England, the only method to propagate it is, by parting the roots in the same manner as is practised for Auriculas; the best time for this is about Michaelmas, soon after which the leaves decay.

The second sort is very like the first, but the flowers are much less, and their empalements are larger; this grows naturally in Siberia, but is with great difficulty kept in a garden.

CORYLUS. Lin. Gen. Plant. 953. Tourn. Inst. R. H. 581. [so called from Κόρυλος, Gr. a Hazel, or Filbert-tree. It is also called Avellana, from Avella, a town in Campania, where it grew in great plenty.] The Hazel, or Nut-tree.

The CHARACTERS are,

It hath male and female flowers growing at remote distances on the same tree. The male flowers are produced in long scaly katkins, each scale including a single flower, having no petals, but eight short stamina fastened to the side of the scale, and terminated by oblong erect summits. The female flowers are included in the future bud, sitting close to the branches; these have a thick two-leaved perianthium, torn on the border, sitting under the flower when it is small, but afterward is enlarged to the size of the fruit; it hath no petal, but a small round germen occupies the center, supporting two bristly coloured styles, which are longer than the empalement, crowned by two single stigmas. The germen afterward becomes an oval nut, shaved at the base, and compressed at the top, ending in a point.

This genus of plants is ranged in the eighth section of Linnæus's twenty-first class, intitled Monœcia Polyandria, from there being male and female flowers on the same plant, and the male flowers having many stamina.

The SPECIES are,

1. **CORYLUS** (*Avellana*) stipulis ovatis obtusis. Hort. Cliff. 448. Hazel Nut with oval blunt stipule. *Corylus Sylvestris.* C. B. P. 418. Wild Hazel Nut.
2. **CORYLUS** (*Maxima*) stipulis oblongis, obtusis, ramis erectioribus. Hazel with oblong blunt stipule, and the branches growing more erect. *Corylus fativa fructu oblongo.* C. B. P. 418. The Filbert.
3. **CORYLUS** (*Colurna*) stipulis linearibus acutis. Hort. Cliff. 448. Hazel with narrow acute stipule. *Corylus Byzantina.* H. L. 191. Byzantine Nut.

The first of these trees is common in many woods in England, from whence the fruit is gathered in plenty, and brought to the London markets by the country people. This tree is seldom planted in gardens (except by persons curious in collections of trees and shrubs;) it delights to grow on a moist strong soil, and may be plentifully increased by suckers from the old plants, or by laying down their branches, which, in one year's time, will take sufficient root for transplanting; and these will be much handsomer and better rooted plants than suckers, and will greatly outgrow them, especially while young.

There is a variety of this with fruit growing in great clusters at the end of the branches, which is distinguished by the title of Cluster Nut; but as this is supposed to be only a variety, which accidentally came from the other, I have not distinguished it; however, this may be continued by layers, so the kind may always be preserved.

The second sort is by many supposed to be only a seminal variety from the first, which hath been improved by culture; but this is very doubtful, for I have several times propagated both from the nuts,

but never have found them vary from one to the other, though they have altered in the size and colour of their fruit, from the sorts which were sown; but as the shrubs of this grow more erect than those of the other, and the stipulæ are different in their shape, so I have enumerated it as a distinct sort; of this there are the red and white Filberts, both which are so well known, as to need no description.

The third sort grows naturally near Constantinople; the nuts of this are large, roundish, and in shape like those of the common Hazel, but are more than twice their size. The cups in which the nuts grow are very large, so as almost to cover the nut, and is deeply cut at the brim. This sort is not common in England, but I take those large nuts which are annually imported from Barcelona in Spain, to be of the same kind, the nuts being so alike, as not to be distinguished when out of their cups; and those of the Spanish sort come over naked, so I cannot with certainty say how they essentially differ.

All these sorts may be propagated by sowing their nuts in February; which, in order to preserve them good, should be kept in sand in a moist cellar, where the vermin cannot come at them to destroy them nor should the external air be excluded from them, which would occasion their growing mouldy.

The manner of sowing the seeds being well known to every one, I need not here mention it, especially since it is not the surest way to obtain the sorts desired; for they seldom prove so good as the nuts which were sown, or at least not one in four of them will; and the method of propagating them by layers being not only the surest, but also most expeditious, is what I would recommend to every one who would cultivate these trees for the sake of their fruits.

CORYMBIFEROUS PLANTS are such as have a compound discous flower, but their seeds have no down adhering to them. The name is taken from the manner of bearing its flowers in clusters, and spreading round in the form of an umbrella. Of this kind is the Corn Marigold, common Ox Eye, the Daisy, Camomile, Mugwort, Feverfew, &c. Mr. Ray distinguishes them into such as have a radiated flower, as the Sun Flower, Marigold, &c. and such as have a naked flower, as the Lavender Cotton and Tansey, and also those that are akin to them, as Scabious, Teasel, Carduus, &c.

CORYMBIUM.

The CHARACTERS are,

It hath an empalement of two leaves, having six angles; the small leaves are erect and close together their whole length, and are triangular on their outside, cut into three segments, and are permanent. The flower has one petal, which is equal, having a very short tube, cut into five segments at the brim, which spread open; it hath five erect stamina sitting within the tube, crowned with oblong erect summits, shorter than the petal, joining in a cylinder: the germen is situated within the empalement, at the bottom of the petal, supporting a single erect style the length of the petal, terminated by a bifid oblong stigma; the germen afterward becomes an oblong seed, having a sort of down adhering to it.

This genus of plants is ranged in the sixth section of Linnæus's nineteenth class, intitled Syngenesia Monogamia, the flower having five stamina which join by their summits, and is succeeded by one seed.

We know but one SPECIES of this genus, viz.

CORYMBIUM (*Africanum*). Hort. Cliff. 494. *African Corymbium.* Bupleurifolia femine papposo, valerianoides umbellata, cauliculi scabri. Pluk. Alm. 73.

This plant grows naturally at the Cape of Good Hope; it rises with an erect rough stalk about a foot high, with a single leaf at each joint, which half embrace the stalk with their base. The leaves are long, narrow, and triangular, and have a downy substance intermixed with them at their base; the upper part of the stalk divides into several foot-stalks, which are terminated by purple flowers of one petal, cut into five parts at the brim, each being succeeded by an oblong seed.

It is propagated by seeds, which should be sown in a small pot filled with light earth as soon as it is received from abroad; the pots should be plunged into a bed of tanners bark, where the heat is near spent, and covered with a common frame in winter, to protect the seeds from frost, snow, and hard rains. In the spring, if the pots are removed into a moderate hot-bed, the plants will soon appear: when they are about an inch high, they should be each transplanted into a separate small pot, observing to shade them until they have got new roots; soon after which they should be gradually inured to the open air, and in June they should be placed abroad in a sheltered situation; where they may remain till October, when they should be placed in a common frame, where they may be protected from frost, being too tender to live abroad in England.

CORYMBUS [Κόρυμβος, Gr.] signifies among botanists, round clusters of berries, as those of Ivy.

Jungius uses it to signify the extremity of a stalk, so subdivided and laden with flowers, or fruits, as to compose a spherical figure.

It is also by modern botanists used to signify a compound discous flower, which does not fly away in down, as the Chrysanthemum, Daisy, Chrysocome, &c. For these kind of flowers, being spread into breadth, do, after a sort, resemble an umbrella, or bunch of Ivy-berries.

COSTUS. Lin. Gen. Plant. 3.

The CHARACTERS are,

It hath a simple spadix and spathe, with a small empalement, divided into three parts, sitting on the germen. The flower hath three concave petals, which are erect and equal, with a large oblong nectarium of one leaf, having two lips, the lower being broad, and as long as the petal. The upper is shorter and spear-shaped, changing to a stamina; this is fastened to the upper lip of the nectarium, to which adheres a bipartite summit. The germen is situated within the receptacle of the flower, which is roundish, supporting a slender style, crowned by a compressed indented stigma. The germen afterward becomes a roundish capsule with three cells, containing several triangular seeds.

This genus of plants is ranged in the first section of Linnaeus's first class, intitled Monandria Monogynia, the flower having but one stamen and one style.

We have but one SPECIES of this plant, viz.

COSTUS (*Arabicus*). Hort. Cliff. 2. *Costus Arabicus*. C. B. P. 36. *Arabian Costus*.

This hath a fleshy jointed root like that of Ginger, which propagates under the surface as that doth; from which arise many round, taper, herbaceous stalks, garnished with oblong smooth leaves, embracing the stalks like those of a Reed; these stalks rise near two feet high; out of the center, the club, or head of flowers is produced, which is near two inches long, the thickness of a man's finger, and blunt at the top, composed of several leafy scales, out of which the flowers come; these have but one thin white petal, which is of short duration, seldom continuing longer than one day before it fades, and is never succeeded by seeds in this country. The time of its flowering is very uncertain, for sometimes it flowers late in the winter, and at other times it has flowered in summer, so is not constant to any season in England. It grows naturally in most parts of India. This is propagated by parting of the roots; the best time for doing this is in the spring, before the roots put out new stalks. The roots must not be divided too small, because that will prevent their flowering. They should be planted in pots, filled with light kitchen-garden earth, and plunged into the tan-bed in the stove, where they should constantly remain, and may be treated in the same manner as the Ginger, which is fully treated of under the article **AMOMUM**.

The roots of this plant were formerly imported from India, and were much used in medicine; but of late years they have not been regarded, the roots of Ginger being generally substituted for these.

COTINUS. See RHUS.

COTONEA MALUS. See CYDONIA.

COTONEASTER. See MESPILUS.

COTULA. Lin. Gen. Plant. 868. *Annathocyclus*. Vaill. Act. Reg. Scien. 1719. *Mayweed*.

The CHARACTERS are,

It hath a flower composed of hermaphrodite florets in the disk, and female half florets which form the rays; these are included in one common convex empalement, divided into several oval parts. The hermaphrodite florets are tubular, and cut into four unequal segments at the top; these have four small stamina, terminated by tubular summits, and have two obtuse stigmas, having one small, oval, angular seed to each. The female half florets have an oval compressed germen, supporting a slender style, crowned by two stigmas, but have no stamina; these are succeeded by single heart-shaped seeds, plain on one side, and convex on the other, with an obtuse border.

This genus of plants is ranged in the second section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia superflua; the plants of this section have hermaphrodite and female flowers, which are fruitful.

The SPECIES are,

1. **COTULA** (*Anthemoides*) foliis pinnato-multifidis, corollis radio destitutis. Hort. Cliff. 417. *Mayweed with many pointed winged leaves, and no rays to the flower. Chamæmelum luteum capite aphylo*. C. B. P. 135.
2. **COTULA** (*Turbinata*) receptaculis subtus inflatis, turbinatis. Hort. Cliff. 417. *Mayweed whose receptacles are swollen and turbinated beneath. Cotula Africana calice eleganter caesio*. Tourn. Inst. R. H. 495.
3. **COTULA** (*Coronopi folia*) foliis lanceolato-linearibus, amplexicaulibus pinnatifidis. Hort. Cliff. 417. *Mayweed with narrow spear-shaped leaves embracing the stalk, having many points. Chrysanthemum exoticum minus, capite aphylo, Chamæmeli nudi facie*. Breyn. Cent. 156.

The first sort grows naturally in Spain, Italy, and the Archipelago; this is an annual plant, which rises with a branching stalk half a foot high, garnished with leaves which are finely divided like those of Chamomile. The flowers are produced singly at the end of the branches, which are very like those of the naked Chamomile, but the heads rise higher in the middle like a pyramid. This flowers in May and June, and the seeds ripen in August. If the seeds of this sort are permitted to scatter, the plants will come up in the spring, and require no other care but to keep them clean from weeds, and thin the plants where they are too close.

The second sort grows naturally at the Cape of Good Hope, from whence I have received the seeds; this is an annual plant, sending out many branching stalks from the root, which spread on the ground, and are garnished with very fine divided leaves, covered with a lanugo, or cotton. The flowers are produced singly upon long foot-stalks, arising from the side of the branches; these have a narrow border of white rays, with a pale yellow disk. It flowers in June and July, and the seeds ripen in autumn. This sort must be raised on a moderate hot-bed in the spring, and when the plants have obtained strength, they may be transplanted into a warm border, where they will ripen their seeds very well.

The third sort is an annual plant, which sends out trailing stalks about six inches long, garnished with succulent leaves, in shape like those of Buckhorn Plantain. The flowers grow from the divisions of the stalks upon short weak foot-stalks, being destitute of rays; they are of a sulphur colour, and appear about the same time with the former. If the seeds of this sort are sown on a warm border where the plants are to remain, they will require no other culture but to keep them clean from weeds. The flowers of the two last sorts stand erect, when they first appear, but so soon as the florets are impregnated, and their colour changes, the foot-stalks become very flaccid toward the top, and the flowers hang downward; but when the seeds are ripe, the foot-stalks become

stiff,

stiff, and the heads stand erect for the winds to disperse the seeds.

COTYLEDON. Lin. Gen. Plant. 512. Tourn. Inst. R. H. 90. tab. 19. [*Κοτυλιδών*, Gr. of *Κοτυλή*, Gr. a cavity; because the leaves of this are hollowed like the navel, or because it resembles a vessel wherewith the ancients used to draw water.] Navelwort.

The CHARACTERS are,

The flower hath a small empalement of one leaf, divided into five parts at the top. It hath one funnel-shaped petal, cut into five parts at the brim, which turn backward. It hath five germina, which have each a squamous concave nectarium at their base, and each sustains a style, crowned by a single stigma; these are attended by ten erect stamina, which are terminated by erect summits, having four furrows. The germen afterwards become so many oblong swelling capsules, opening longitudinally, with one valve, filled with small seeds.

This genus of plants is ranged in the fourth section of Linnæus's tenth class, intitled Decandria Pentagynia, the flower having ten stamina and five styles.

The SPECIES are,

1. **COTYLEDON** (*Umbilicus*) foliis cuculato-peltatis, serrato-dentatis, alternis, caule ramoso, floribus erectis. Lin. Sp. Plant. 429. *Navelwort with hooded leaves sharply indented, growing alternate, and a branching stalk with erect flowers. Cotyledon major. Greater Navelwort. Umbilicus Veneris. Clus. H.*
2. **COTYLEDON** (*Spinoso*) foliis oblongis spinoso-mucronatis, caule spicato. Lin. Sp. Plant. 429. *Navelwort with oblong pointed leaves, ending with a spine, and a spiked stalk.*
3. **COTYLEDON** (*Serrata*) foliis ovalibus, crenatis, caule spicato. Lin. Sp. Plant. 429. *Navelwort with oval crenated leaves and a spiked stalk. Cotyledon Cretica, folio oblongo, fimbriato. Hort. Elth. 113. tab. 95. Navelwort of Crete, with an oblong fringed leaf.*
4. **COTYLEDON** (*Hemisphærica*) foliis semiglobosis. Hort. Cliff. 176. *Navelwort with semiglobular leaves. Cotyledon Capensis, folio semiglobato. Hort. Elth. 112. tab. 94.*
5. **COTYLEDON** (*Orbiculata*) foliis subrotundis, planis integerrimis. Hort. Cliff. 276. *Navelwort with roundish, plain, entire leaves. Sedum Africanum frutescens, incanum, orbiculatis foliis. H. L. 349.*
6. **COTYLEDON** (*Ramosissimo*) caule ramosissimo, foliis rotundis, planis, marginibus purpureis. *Navelwort with a very branching stalk, and round, plain, hairy leaves, with purple edges.*
7. **COTYLEDON** (*Arborescens*) caule ramoso, succulento, foliis obversè ovatis, emarginatis, marginibus purpureis. *Navelwort with a branching succulent stalk, and obverse oval leaves, which are indented at the top, and have purple borders. Cotyledon major, arborescens Afra, foliis orbiculatis, glaucus, limbo purpureo, & maculis viridibus ornatis. Boerh. Ind. alt. 1. p. 287.*
8. **COTYLEDON** (*Ovata*) caule ramoso, succulento, foliis ovatis, planis, acuminatis oppositis semiamplexicaulibus. *Navelwort with a succulent branching stalk, and oval, plain, pointed leaves growing opposite, which half embrace the stalk.*

10. **COTYLEDON** (*Laciniata*) foliis laciniatis, floribus quadrifidis. Hort. Cliff. 175. *Navelwort with cut leaves, and four-pointed flowers. Cotyledon Afra, folio crasso lato laciniato, flosculo aureo. Boerh. Ind. alt. 288.*

The first sort, which is that used in medicine, grows upon old walls and buildings in divers parts of England, particularly in Shropshire and Somersetshire; in both which counties it greatly abounds upon old buildings, and on rocky places, but is not often found wild near London, nor often cultivated in gardens. This hath many round succulent leaves, whose foot-stalks are placed almost in the center, so as to resemble a target. They are alternately sawed on their edges, which frequently turn inward; the upper

surface of the leaves are hollow in the middle, where the foot-stalks are joined on the lower side, so as to resemble a navel, from whence the plant was titled Navelwort. From between the leaves arise the foot-stalks of the flowers, which in some places grow near three feet high, and in others not more than six inches, their lower part being garnished with leaves, and their upper part with flowers, which stand close to the side of the branches, and grow erect; they are of a whitish yellow colour, and appear in June. It requires a dry rubbishy soil, and to have a shady position. This is a biennial plant, so that after it has perfected seed, the plant decays; but if the seeds are scattered on walls and old buildings as soon as it is ripe, or if the seeds are permitted to fall upon such places, the plants will come up, and thrive much better than when they are sown in the ground; and when once the plants are established upon an old wall or building, they will sow their seeds, and maintain their place better than when cultivated with more care. The second sort grows naturally in Siberia, from whence it was brought to the imperial garden at Petersburg. This was sent me by Dr. Amman, the late professor of botany in that garden. It is a low plant, in shape like the Houseleek, but the leaves are longer, and terminate in soft spines. The flower-stalks rise about four inches high, and support four or five whitish flowers, which are cut at the brim into five parts. These appear in April, and are sometimes succeeded by seeds in England. This sort requires a very shady situation, for if it is exposed to the sun in summer, the plants will soon decay. It is propagated by offsets like the Houseleek, and requires a pretty strong soil.

The third sort grows naturally in the Levant. This hath a fibrous root, from which is produced a single upright succulent stalk, garnished with oblong, thick, succulent leaves, placed alternate, which are sawed on their edges. The upper part of the stalk is garnished with purplish flowers, growing in a loose spike, two or three being joined on the same foot-stalk, which is very short. The flowers appear in June, and the seeds ripen in autumn. It is a biennial plant, which decays soon after the seeds are ripe. If this sort is sown upon a wall, it will thrive better than in the ground, and be less liable to suffer by frost; so that where the seeds scatter themselves in such situations, the plants thrive better than when they are cultivated.

The fourth sort grows naturally at the Cape of Good Hope. This hath a thick succulent stalk, which rarely rises above a span high, dividing into many branches, garnished with short, thick, succulent leaves, which are very convex on their under side, but plain on their upper, not more than half an inch long, and a quarter broad, of a grayish colour spotted over with small green spots, and sit close to the branches: the foot-stalks of the flower rise from the top of the branches, and are six inches long, naked, and support five or six flowers, which come out alternate from the side, sitting very close to the stalks; they are tubular, and cut into five parts at the top; these are greenish, with purple tips. It flowers in June and July, but never produces seeds in England.

The fifth sort grows naturally upon dry gravelly spots at the Cape of Good Hope. It hath a thick succulent stalk, which by age becomes ligneous, and rises three or four feet high, sending out crooked branches, which grow irregular, garnished with thick, fleshy, succulent leaves about two inches long, and near as wide toward the top; they are narrow at their base, and rounded at the top, of a sea-green colour, with a purple edge, which is frequently irregularly indented. The flowers grow upon thick succulent foot-stalks, which arise from the end of the branches, and are near a foot long, naked, and supporting eight or ten flowers, growing in an irregular umbel at the top; these are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the stamina and style being longer than

than the tube of the flower, hanging downward. This sort flowers in July, August, and September, but doth not ripen seeds in England.

The sixth sort is also a native of the Cape of Good Hope. This hath a short, thick, succulent stalk, which rarely rises more than a foot high, branching out on every side, so as to spread over the pots in which they are planted: they become woody by age, and are closely garnished with thick round leaves, of a grayish colour, with purple borders, plain on their upper side, but convex on their under, and very fleshy, of an herbaceous colour within, and full of moisture. This sort hath not flowered in England, so far as I can learn, for I have kept plants of it which were twenty years old, but never attempted to flower. It is undoubtedly a different sort from the former, although they have been supposed to be the same by some writers.

The seventh sort is somewhat like the sixth, but the stalks rise higher, the leaves are much larger, and shaped more like those of the fifth, but are spotted on their upper side with great numbers of dark green spots; they have a deep border of purple on their edges, and sit close to the branches. This hath not as yet flowered in England. This is also a native of *Æthiopia*.

The eighth sort hath been of late years introduced into the gardens in Holland, from the Cape of Good Hope, where it grows naturally, and was sent me by Dr. Adrian Van Royen, late professor of botany at Leyden. This rises with a succulent stalk near three feet high, which divides into many branches, growing erect, garnished with oval succulent leaves, placed opposite; they are of a lively green, and end in points, and half embrace the stalks with their base. This sort hath not as yet produced any flowers in England.

The ninth sort grows on rocky places at the Cape of Good Hope, from whence it was first brought to the gardens in Holland, and hath since been spread into most parts of Europe, where there are curious persons who preserve exotic plants in their gardens: this hath a short, greenish, succulent stalk, which seldom rises more than a span high, dividing into several irregular branches, garnished with thick succulent leaves four inches long, and half an inch broad, and as much in thickness, having a broad concave furrow on their upper side, running almost their whole length, and are convex on their under side, of a bright green, with a purple tip. The foot-stalks of the flowers are produced at the end of the branches, and rise near a foot high, having here and there an oblong pointed leaf, growing on their side. The flowers stand upon short foot-stalks, which branch out from the principal stem; these are yellow, having pretty long tubes, which are cut at the top into five parts, and are reflexed backward. The flowers of this sort hang downward, and the stamina are longer than the tube of the flower; the reflexed parts of the petal are tipped with purple. Dr. Linnaeus has supposed this to be the same with the fifth sort, but whoever has seen both plants, cannot doubt of their being distinct species.

The tenth sort grows naturally in the warm parts of Africa, so is much more tender than either of the other sorts: this rises with an upright stem about a foot high, which is jointed and succulent, garnished with broad leaves, which are deeply cut on their edges; they are of a grayish colour, placed opposite, and almost embrace the stalks with their base. The foot-stalks of the flowers arise from the end of the branches, which are about six inches long, sustaining seven or eight small flowers of a deep yellow colour, which are divided into four parts almost to the bottom. The stamina of these flowers are not longer than the short tube. This flowers at different seasons of the year, but never produces any seeds in England. This sort requires a warm stove to preserve it through the winter in England, nor should it be exposed abroad in summer; for if it receives much wet, the stalks are

very subject to rot; so that it should constantly remain either in the stoves, or in summer should be placed in an airy glass-case with other tender succulent plants, where they may have free air in warm weather, and be screened from cold and wet; but in autumn they must be removed into the stove, where they should be kept in a moderate temperature of warmth: this is propagated by cuttings, which should be taken off in summer, and planted into small pots, and plunged into a moderate hot-bed, and when they have taken root, they should be removed into the stove. This plant must have but little water, especially in winter.

The African kinds are all of them propagated by planting cuttings in any of the summer months, which should be laid in a dry place for a fortnight or three weeks after they are taken from the plant, before they are planted; for these abound with juice through every part of the plant, which will certainly rot the cuttings, if they are not suffered to lie out of the ground, that the wounded part may heal over, and the great redundancy of sap evaporate. The soil in which these plants thrive best, is one third fresh light earth from a pasture, one third sand, and the other third part lime-rubbish and rotten tan, in equal quantities; these should be well mixed, and laid in a heap six or eight months before it is used, turning it over five or six times, that the parts may the better incorporate; and before it is used, it will be proper to pass it through a screen, to separate the large stones, clods, &c. therefrom.

Having prepared the earth, and your cuttings being in a fit order for planting, you must fill as many half-penny pots with earth as you have cuttings to plant; then put one cutting in the middle of each pot about two or three inches deep or more, according to their strength; then give them a little water to settle the earth close about them, and set the pots in a warm shady place for about a week, to prepare the cuttings for putting forth roots; after which they should be plunged into a moderate hot-bed of tanners bark, which will greatly facilitate their rooting; but observe to give them air, by raising the glasses at all times when the weather will permit, as also to shade the glasses in the heat of the day.

In about six weeks or two months time after planting, these cuttings will be rooted, when you must begin to expose them to the open air by degrees, first drawing the pots out of the tan, and setting them on the top, then raise the glasses very high in the day-time; and in about a week after remove the pots into a green-house, and there harden them for another week; after which they may be exposed to the open air in a well defended place, observing not to set them into a place too much exposed to the sun, until they have been inured to the open air for some time.

In this place the plants may remain until the beginning of October, at which time you should remove them into the conservatory, placing them as near the windows as possible at first, letting them have as much free open air as the season will permit, by keeping the windows open whenever the weather is good; and now you must begin to abate your waterings, giving it to them sparingly; but you should not suffer their leaves to shrink for want of moisture, which is another extreme some people run into for want of a little observation; for when they are suffered to shrink for want of sufficient moisture to keep their vessels distended, they are rendered incapable of discharging this moisture whenever they receive it again. The tenth sort should be placed in a moderate stove in winter, nor must it be set abroad till Midsummer, for it is much tenderer than any of the others.

The best method to treat most of these plants is, to place them in an open, airy, dry glass-case, among *Ficoideffes* and African *Housleeks*, where they may enjoy as much of the sun-shine as possible, and have a free, dry, open air; for if these are placed in a common green-house among shrubby plants, which perspire freely, it will fill the house with a damp air, which

which these succulent plants are apt to imbibe; and thereby becoming too replete with moisture, often cast their leaves, and many times their branches also decay, and the whole plant perishes.

CRAMBE. Lin. Gen. Plant. 739. Tourn. Inst. R. H. 211. tab. 100. [Κραμβή, Gr.] Sea Cabbage.

The CHARACTERS are,

The empalement of the flower is composed of four oval concave leaves which spread open. The flower hath four petals, placed in form of a cross, which are large, oblong, and spread open; it hath six stamina, two of which are the length of the empalement, the other four are longer, and bifid at their points; these are terminated by single summits, which branch into threads on their outside. The petals have boney glands on their inside, which are longer than the stamina. It hath an oblong germen, but no style, crowned by a thick stigma. The germen afterward becomes a round dry capsule, with one cell, inclosing one roundish seed. This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradynamia filiquosa, the flower having four long and two short stamina, and the seeds growing in pods.

The SPECIES are,

1. CRAMBE (*Maritima*) foliis cauleque glabris. Fl. Suec. 570. *Sea Cabbage with smooth stalks and leaves.* Crambe maritima brassicæ folio. Tourn. Inst. 211.

2. CRAMBE (*Suecica*) foliis profundè laciniatis, caule erecto, ramoso. *Sea Cabbage with leaves deeply cut, and an upright branching stalk.*

3. CRAMBE (*Orientalis*) foliis scabris, caule glabro. Lin. Sp. Plant. 671. *Sea Cabbage with rough leaves and a smooth stalk.* Crambe foliis & foliolis alternatim pinatifidis. Prod. Leyd. 330.

4. CRAMBE (*Hispanica*) foliis cauleque scabris. Hort. Upsal. 193. *Sea Cabbage with rough stalks and leaves.* Rapistrum maximum rotundifolium monospermum. Corn. Canad. 147.

The first sort sends out many broad smooth leaves, which are deeply jagged on their sides in obtuse segments, and are of a grayish colour, spreading near the ground; between these arise a thick smooth foot-stalk about one foot high, which spreads out into many branches, which have at each joint one leaf of the same form as those below, but much less; these foot-stalks subdivide again into many smaller, which are garnished with white flowers, growing in a loose obtuse spike, composed of four concave petals, placed in form of a cross; these are succeeded by round dry seed-vessels about the size of large Pease, having a single seed in each. It flowers in June, and the seeds ripen in autumn. The roots of this sort creep under ground, whereby it propagates very fast.

The seeds of the second sort were sent me from Peterburgh for the first sort, from which it differs greatly. This hath a perennial root, which sends out several oblong, smooth, pointed leaves, irregularly cut on their sides into acute segments almost to the midrib; these are very smooth, and of a sea-green colour: between these arise the stalk, which grows three feet high, garnished below by oblong pointed leaves, which are acutely indented on their edges. The stalks branch out into many smaller, and these subdivide again into less, which are garnished with loose spikes of white flowers like those of the first sort, which are succeeded by seeds of the same form. This differs greatly from the first in the shape of its leaves, which are longer, ending in points, and the segments do the same; whereas those of the other are blunt, and not half so deeply cut. The stalks rise more than twice the height of the first, branch out more, and the branches grow more erect; and these differences are constant, where the plants of both sorts grow in the same soil.

The third sort grows naturally in the East. This hath a biennial root, from which arise many leaves in the spring, that are alternately divided to the midrib; and these divisions are again alternately cut on

their edges into many points, so that they have the appearance of winged leaves, and are of a grayish colour. The stalks rise about two feet high, and divide into many branches, which are terminated by loose panicles of small white flowers, placed in form of a cross, which are succeeded by small round capsules, each containing a single seed. This flowers in June, and the seeds ripen in autumn, soon after which the roots decay.

The fourth sort is an annual plant, which grows naturally in Spain and Italy. This rises with a very branching stalk near three feet high, garnished with roundish heart-shaped leaves, indented on their edges, standing upon long foot-stalks; the branches subdivide into many slender ones, which end in long loose spikes of small white flowers, which are succeeded by small, round, dry seed-vessels, which contain a single seed. The leaves and stalks of this sort are rough. It flowers in June, and the seeds ripen in autumn.

The first species is found wild upon sea-shores in divers parts of England, but particularly in Sussex and Dorsetshire in great plenty, where the inhabitants gather it in the spring to eat, preferring it to any of the Cabbage kind; as it generally grows upon the gravelly shore, where the tide overflows it, the inhabitants observe where the gravel is thrust up by the shoots of this plant, and open the gravel, and cut the shoots before they come out, and are exposed to the open air, whereby the shoots appear as if they were blanched; and when they are cut so young, they are very tender and sweet; but if they are suffered to grow till they are green, they become tough and bitter. This plant may be propagated in a garden, by sowing the seed soon after it is ripe, in a sandy or gravelly soil, where it will thrive exceedingly, and increase greatly by its creeping roots, which will soon overspread a large spot of ground, if encouraged; but the heads will not be fit to cut until the plants have had one year's growth: and in order to have it good, the bed in which the plants grow, should, at Michaelmas, be covered over with sand or gravel about four or five inches thick; which will allow a proper depth for the shoots to be cut before they appear above ground; and if this is repeated every autumn, in the same manner as is practised in earthing of Asparagus-beds, the plants will require no other culture. This may be cut for use in April and May, while it is young; but if the shoots are suffered to remain, they will produce fine regular heads of white flowers, which appear very handsome, and will perfect their seeds, by which they may be propagated.

The other sorts are only preserved in curious gardens of plants for variety, but are not of any use or beauty. The perennial sorts may be propagated in the same manner as the first.

CRANE'S-BILL. See GERANIUM.

CRANIOLARIA. Lin. Gen. Plant. 670. Martynia. Houst. Gen.

The CHARACTERS are,

The flower hath a permanent empalement, composed of four short narrow leaves which spread open, with a large swollen head, which is cut longitudinally on the side. The flower hath one petal, which is unequal, having a very long narrow tube, whose brim is divided into two lips; the upper being roundish and entire, but the under is divided into three parts, the middle segment being the largest. It hath four stamina, two of which are the length of the tube, and two are shorter; these are terminated by single summits; at the bottom of the tube is situated an oval germen, supporting a slender style, crowned by an obtuse thick stigma. The germen afterward becomes an oval leathery fruit, pointed at both ends, opening with two valves, inclosing a depressed woody nut, pointed at both ends, and recurved, having two or three furrows, so as to resemble a skull, opening in two parts.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flowers having two long and

two short stamina, and the seeds being included in a capsule.

The SPECIES are,

1. CRANIOIARIA (*Annua*) foliis cordatis, angulatis lobatis. Lin. Sp. Plant. 862. *Cranioiaria with angular heart-shaped leaves*. Martynia annua, villosa, & viscosa, aceris folio, flore albo, tubo longissimo. Houst. MSS.

2. CRANIOIARIA (*Fruticosa*) foliis lanceolatis dentatis. Lin. Sp. Plant. 618. *Cranioiaria with spear-shaped indented leaves*. Gesnera arborescens amplo flore fimbriato & maculoso. Plum. Nov. Gen. 27.

The first sort was discovered in the neighbourhood of Carthage in New Spain, by the late Dr. William Houstoun, who sent the seeds to England. This is an annual plant, which rises with a branching stalk about two feet high; the branches come out opposite, which are hairy and viscous; the leaves also are placed opposite, upon very long foot-stalks; these are of different shapes, some of them are divided into five lobes, others into three, and some are almost heart-shaped, ending in acute points; they are hairy and clammy. The flowers are produced from the side, and also at the end of the branches, standing on short foot-stalks, having an inflated sheath or cover, out of which the tube of the flower arises, which is seven or eight inches long, and very slender; but at the top is divided into two lips, the under being large, divided into three broad segments, the middle being larger than the other two; the upper lip is roundish and entire: the flowers are succeeded by oblong fruit, having a thick dry skin, which opens lengthways, inclosing a hard furrowed nut, with two recurved horns. This is an annual plant, whose seeds must be sown on a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a separate small pot, filled with light fresh earth, and plunged into a moderate hot-bed, carefully shading them from the sun till they have taken new root; after which they should have free air admitted to them in proportion to the warmth of the season, to prevent their drawing up weak, and afterwards treated in the same manner as other tender exotic plants, being too tender to thrive in the open air in England; so that when they are grown too large to remain under the frames, they should be removed into the bark-stove, and plunged into the tan-bed, where they will flower in July, and with good management they often perfect their seeds in autumn. But the seeds of this plant should remain on till they drop, otherwise they will not grow, for the outer covers of these seeds split open and drop off like those of the Almond, before the seeds are fully ripened.

The second sort grows naturally at the Havannah, and in some of the other islands in America. This rises with a shrubby stalk to the height of ten or twelve feet, dividing upward into a few branches, which are garnished with spear-shaped leaves, cut on their edges; these are soft and hairy. The flowers are produced from the side of the branches, growing several together on the same foot-stalk; they are shaped like those of the Foxglove, of a greenish yellow colour, with brown spots on the inside; the flowers have a swelling tube, which is recurved, and the brim is slightly divided into five unequal segments. These appear in July, but are not succeeded by seeds in England.

This sort is propagated by seeds, which must be procured from the countries where it grows naturally, and should be sown on a hot-bed in the spring; when the plants are fit to remove, they should be each planted into a separate small pot, filled with light kitchen-garden earth, and plunged into a fresh hot-bed, where they must be shaded from the sun till they have taken fresh root; then they must have air admitted to them, according to the warmth of the season, and frequently watered during the heat of summer. In autumn they must be removed into the bark-stove, and plunged into the tan-bed. During the winter season, the plants should not have much wa-

ter, and may be treated in the same manner as other tender plants from those countries. The plants seldom flower in England till the third year; and as they do not produce seeds here, it is with difficulty the sort is preserved in the European gardens, as there is no other method of propagating the plants but by seeds.

- CRASSULA. Dillen. Hort. Elth. 114. Lin. Gen. Plant. 352. Lesser Orpine, or Live-ever. This name was formerly applied to the Anacampseros, or Orpine.

The CHARACTERS are,

The flower hath a five-leaved empalement. The corolla consists of five narrow petals, which are joined at their base, are reflexed, and spread open at the brim. In the bottom of the tube are situated five nectaries, and there are five stamina situated round these, which arise from the bottom of the tube, and extend to the brim. At the bottom of the tube are placed five oblong pointed germina; after the flower is past, these become five capsules, opening lengthways, and filled with small seeds.

This genus of plants is by Dr. Linnæus ranged in his fifth class of plants, and in the fifth division, intitled Pentandria Pentagynia, which includes those plants whose flowers have five stamina and five styles.

The SPECIES are,

1. CRASSULA (*Coccinea*) foliis planis cartilagineo-ciliatis, basi connato vaginantibus. Vir. Cliff. 26. *Lesser Orpine with plain leaves, having stiff edges set with silver hairs, and their base surrounding the stalk like sheaths*. Cotyledon Africana frutescens, flore umbellato Coccineo. Com. Rar. 24.
2. CRASSULA (*Perfoliata*) foliis lanceolato-subulatis sessilibus connatis, canaliculatis, subtus convexis. Hort. Cliff. 116. *Lesser Orpine with spear-shaped awl-fashioned leaves, surrounding the stalks with their base, channelled on their upper side, and convex on their under*. Crassula altissima perfoliata. Dill. Hort. Elth. 114.
3. CRASSULA (*Cultrata*) foliis oppositis, obtusè ovatis, integerrimis, hinc angustioribus. Hort. Cliff. 496. *Lesser Orpine with oval blunt leaves placed opposite, which are entire, and narrow at their base*. Crassula Anacampserotis folio. Hort. Elth. 115. tab. 65.
4. CRASSULA (*Ciliata*) foliis oppositis, ovalibus, planiusculis, distinctis, ciliatis, corymbis terminalibus. Hort. Cliff. 496. *Lesser Orpine with oblong plain leaves placed opposite, which are bordered with silver hairs, and stalks terminated by a corymbus of flowers*. Crassula caulescens, foliis sempervivi cruciatis. Hort. Elth. 116. tab. 98.
5. CRASSULA (*Scabra*) foliis oppositis, patentibus, connatis scabris ciliatis, corymbis terminalibus. Lin. Sp. Plant. 283. *Lesser Orpine with rough spreading leaves growing opposite*. Cotyledon Africana frutescens, foliis asperis, angustis, acuminatis, flore virescente. Mart. Cent. 24.
6. CRASSULA (*Nudicaulis*) foliis subulatis, radicatis, caule nudo. Hort. Cliff. 116. *Lesser Orpine with awl-shaped leaves which put out roots, and a naked stalk*. Crassula Cæspitosa longifolia. Hort. Elth. 116. tab. 93.
7. CRASSULA (*Punclata*) caule flaccido, foliis connatis, cordatis, succulentis, floribus confertis terminalibus. *Lesser Orpine with a weak stalk growing through the leaves, which are heart-shaped and succulent, and flowers growing in clusters at the end of the branches*.
8. CRASSULA (*Fruticosa*) foliis longis, teretibus, alternis, caule fruticoso, ramoso. *Lesser Orpine with long taper leaves placed alternate, and a branching shrubby stalk*.
9. CRASSULA (*Sedoides*) caule flaccido, prolifero, determinatè-foliofo, foliis patentissimis, imbricatis. Hort. Cliff. 496. *Lesser Orpine with a proliforous weak stalk, which is leafy, and leaves placed in the manner of tiles, and spreading open*. Sedum Afrum, saxatile, foliis sedi vulgaris, in rosam verè compositis. Boerh. Ind. alt. 1. 287.
10. CRASSULA (*Pelucida*) caule flaccido repente, foliis oppositis. Lin. Sp. Plant. 283. *Lesser Orpine with a weak creeping stalk, leaves placed opposite, and a shrubby succulent stalk*. Crassula portulacæ facie repens. Hort. Elth. 119.

11. *CRASSULA (Portulacaria) foliis obovatis, oppositis, caule arboreo.* Lin. Sp. 406. *Lesser Orpine with obverse oval leaves placed opposite, and a tree-like stalk.* *Crassula portulacæ facie arborescens.* Hort. Elth. 120. tab. 90.

The first sort hath a round reddish stalk, which is jointed, rising about three feet high, which divides upward into many irregular branches, garnished with oblong plain leaves placed opposite, having a gristly border, set with small silver hairs, and closely embrace the stalks with their base. The flowers are produced at the end of the branches in close umbels, sitting very close to the end of the branches; these are funnel-shaped, having pretty long tubes cut at the top into five parts, which spread open; they are of a fine scarlet colour, and stand erect; the usual time of their flowering is July or August. This is propagated by cuttings during any of the summer months; these should be cut off about a fortnight before they are planted, and laid in a dry place that the wounded part may heal over; then they should be each planted in a small pot filled with light sandy earth, and plunged into a moderate hot-bed, giving them but little water. In about six weeks these will have put out roots and begin to grow, when they should have a large share of air admitted to them, and must be gradually inured to bear the open air, into which they should be removed, placing them in a sheltered situation, where they may remain till autumn; when they must be removed into a dry airy glass-case, where they may enjoy the sun as much as possible, and be screened from the wet and cold. In warm dry weather, during the summer months while they are abroad, these plants should be gently watered two or three times a week; but in winter they should have very little water, lest it rot their stems. These plants require no artificial heat in winter, but they must be secured from frost and wet.

The second sort will rise with an upright stalk ten or twelve feet high, if it is not broken or injured, but it requires support; for the stalks being slender, and the leaves very weighty, they are very subject to break, especially if they are exposed to the wind. The leaves of this plant are about three inches long; they are hollowed on the upper side, and have a convex ridge on their lower, and are placed opposite, surrounding the stalks with their base; these alternately cross each other; they are very thick, succulent, and of a pale green colour, ending in acute points; at the top of the stalk the flowers are produced in large clusters; they are of a whitish herbaceous colour, having short tubes, which are cut into five parts at the brim, spreading open. The stalk which sustains the flowers is pretty thick and succulent, generally turning first downward, and then upward again, almost in the form of a syphon. It flowers in July, but doth not produce seeds here. This sort is propagated by cuttings in the same manner as the first, and the plants require the same treatment.

The third sort rises with a weak succulent stalk about two feet high, sending out many irregular branches, garnished with oblong, oval, thick leaves, plain on their upper side, but convex below, of a deep green; their borders are set with a few silvery hairs. The stalk which supports the flowers rises from the top of the branches, and is from four to six inches long, putting out several side branches, which grow erect; these are terminated by large clusters of small greenish flowers, which appear in June and July. This is propagated by cuttings in the same manner as the two former, but being pretty hardy, should not be so tenderly treated; for if the cuttings of this are planted in a border of light earth, they will put out roots, and may afterward be taken up and potted, to be sheltered in winter.

The fifth sort hath a very weak succulent stalk, which rises about a foot and a half high, dividing upward into small branches, garnished with thin rough leaves which are flat, near two inches long, and a quarter broad at their base, gradually narrowing to a point;

these are rough, placed opposite, and embrace the stalks with their base. The flowers come out in small clusters at the end of the branches; they are small, and of an herbaceous colour, so make no figure; they appear in June and July. This may be propagated by cuttings, which may be treated in the same manner as the fourth sort.

The sixth sort never rises with a stalk, but the leaves come out close to the ground, forming a sort of head; they are taper, succulent, ending in points, and frequently put out roots; out of the center of these arise the flower-stalk, which grow about six inches high, branching into two or three shoots upward, each being terminated by clusters of greenish flowers, which make no great appearance. It flowers in May, and sometimes again in the latter part of summer. This is propagated by taking off the heads, or side offsets, which should be laid to dry three or four days before they are planted; then they may be treated in the same manner as the other hardier sorts before-mentioned.

The seventh sort hath been lately introduced to the gardens in Holland, from the Cape of Good Hope; it was sent me by Dr. Adrian Van Royen, late professor of botany at Leyden. This hath very slender stalks, which are full of joints, so trail upon the ground, unless they are supported, closely garnished with thick, succulent, heart-shaped leaves, placed opposite, which are closely joined at their base, so that the stalks run through them; they are of a grayish colour; the stalks are divided, and grow about eight or nine inches long, and are terminated by clusters of small white flowers, sitting very close to the top of the stalks; these appear in the spring, and also again in the latter part of summer. It is propagated by cuttings in the same manner as the other hardier sorts, and may be treated in the same way.

The eighth sort was sent me from Leyden, by the gentleman before-mentioned; this rises with a shrubby stalk four or five feet high, dividing into many branches, which at first are taper and succulent, but by age becomes ligneous; they are garnished with very slender, taper, succulent leaves, which are near three inches long, and are flaccid, generally turning downward, especially in winter, when they are in the house; but as it hath not as yet flowered here, I can give no further description of it. This is equally hardy with the former sorts, and takes easily from cuttings, so may be treated in the same way as the former.

The ninth sort is a low plant, with the appearance of Houseleek, having open spreading heads very like those of some sorts of Houseleek, which grow on the ends of very slender trailing stalks, which are produced in plenty on every side the parent plant, in like manner as the childing Marigold. The flower-stalks arise from the center of these heads, which are naked, about four inches long, and are terminated by close clusters of herbaceous flowers, which appear in different seasons of the year. This plant propagates very fast by the side heads, which come out from the parent plant, which frequently put out roots as they trail on the ground, so may be taken off and potted, during any of the summer months; this is equally hardy with the former sorts, so the plants may be treated in the same way.

The tenth sort hath very slender, trailing, succulent stalks, of a reddish colour, which put out roots at the joints as they lie upon the ground. The stalks and leaves of this sort have the appearance of Purslane, but trail upon the ground like Chickweed. The flowers are produced in small clusters at the end of the branches; these are white, with a blush of purple at their brim; they appear in summer at different times, and are often succeeded by seeds, which grow easily. This sort is easily propagated by its trailing branches, and the plants require the same treatment as the other hardy sorts, but unless they are often renewed will decay.

The eleventh sort rises with a very thick, strong, succulent stalk to the height of three or four feet, sending out branches

branches on every side, so as to form a kind of pyramid, the lower branches being extended to a great length, and the other diminishing gradually to the top; these are of a red or a purplish colour, and very succulent; they are garnished with roundish succulent leaves very like those of Purslane, from whence the gardeners have titled it the Purslane-tree.

This sort hath not flowered in England, though it has been many years in the gardens, so that we are not sure if it is properly ranged in this genus; but from the outward appearance it seems to be nearly allied to some of the other species, on which account Dr. Dillenius has placed it here.

It is propagated with great facility by cuttings, which may be planted during any of the summer months; but these should be laid to dry for some days before they are planted, that the wounded part may be healed over, otherwise they will rot. This sort is somewhat tenderer than the four sorts last mentioned, so must be placed in a warm glass-case in winter, where it may enjoy the full sun, and should have very little water during that season. In summer the plants should be placed abroad in a sheltered situation, and in warm weather will require to be refreshed with water twice a week; but as the stalks are very succulent, too much wet at any season is very hurtful to these plants.

All the hardy sorts of *Crassula* may be treated in the same way as the *Ficoides*, and other hardier kinds of succulent plants, with this difference only, not to give them so much water; but the first, second, and eleventh sorts require to be placed in a warm dry glass-case in winter, and must not be so long exposed abroad in the summer as the other species, nor should have much water, especially in the winter.

These plants are preserved in most curious gardens for the sake of variety, which consists more in the outward appearance of their plants, than in the beauty of their flowers, except the first sort, whose flowers are of a beautiful scarlet, and grow in close bunches at the end of the branches; so that when several of the branches are garnished with flowers at the same time, they make a fine appearance, and these flowers continue in beauty a long time; but the flowers of the other sorts are small, and most of them are of an herbaceous colour, so make no figure.

Dr. Dillenius, who first established this genus, and separated the species from *Cotyledon*, to which many of them had been joined by former botanists, made their difference to consist in the shape of the flower; so that all the sorts with long tubulous flowers of one leaf, he placed under the genus of *Cotyledon*, and those whose flowers have five petals, he placed under this genus of *Crassula*: but Dr. Linnæus makes their difference to consist in the number of their stamina, so that all those whose flowers have but five stamina, he ranges under the title of *Crassula*, and those which have ten stamina, he puts under that of *Cotyledon*; so that by his system they are removed to a great distance from each other, and the first sort here mentioned is brought from *Cotyledon*, with whose characters in every other respect it agrees, and is placed here.

CRATÆGUS. Tourn. Inst. R. H. 633. Lin. Gen. Plant. 547. The Wild Service.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five concave segments, which spread open. It hath five roundish concave petals, which are inserted into the empalement, and many stamina, terminated by roundish summits, which are also inserted in the empalement. The germen is situated under the flower, supporting two slender styles, crowned with roundish stigmas. The germen afterwards becomes an oval or roundish umbilicated berry, inclosing two oblong hard seeds.

This genus of plants is ranged in the second section of Linnæus's twelfth class, intitled *Icosandria Digynia*, the flower having twenty or more stamina, which are inserted to the empalement, and two styles.

The SPECIES are,

1. **CRATÆGUS** (*Aria*) foliis ovatis inæqualiter ferratis,

subtus tomentosis. Hort. Cliff. 187. *Wild Service with oval leaves unequally sawed, and woolly on their under side.* *Cratægus folio subrotundo, serrato, subtus incano.* Tourn. Inst. R. H. 633. *Aria Theophrasti*, and in some countries, *The White Beam, or white Leaf-tree.*

2. **CRATÆGUS** (*Torminalis*) foliis cordatis septangulis, lobis infimis divaricatis. Lin. Sp. Plant. 476. *Wild Service with heart-shaped leaves, having seven angles, whose lower lobes spread asunder.* *Cratægus folio laciniato.* Tourn. Inst. 633. *Wild, or Maple-leaved Service.*

3. **CRATÆGUS** (*Alpina*) foliis oblongo-ovatis serratis, utrinque virentibus. *Wild Service with oblong, oval, sawed leaves, which are green on both sides.* *Cratægus folio oblongo, serrato, utrinque virenti.* Tourn. Inst. 633.

4. **CRATÆGUS** (*Coccinea*) foliis ovatis repando-angulatis serratis glabris. Hort. Cliff. 187. *Cratægus with oval, smooth, sawed leaves, having angles.* *Mespilus spinosa*, sc. *oxyacantha Virginiana maxima.* Tourn. Inst. 633. Commonly called *Cockspur Hawthorn.*

5. **CRATÆGUS** (*Crus Galli*) foliis lanceolato ovatis serratis glabris, ramis spinosis. Lin. Sp. 682. *Cratægus with oval, spear-shaped, sawed leaves, and prickly branches.* *Mespilus aculeata pyrifolia denticulato splendens, fructu insigni rutilo, Virginienfis.* Pluk. Alm. 249. Commonly called *Virginian L'Azarole.*

6. **CRATÆGUS** (*Lucida*) foliis lanceolatis serratis lucidis, spinis longissimis, floribus corymbosis. *Cratægus with lucid, spear-shaped, sawed leaves, very long spines, and flowers in a corymbus.* *Mespilus prunifolius, spinis longissimis fortibus, fructu rubro magno.* Flor. Virg. 55.

7. **CRATÆGUS** (*Azarolus*) foliis obtusis subtrifidis dentatis. Lin. Sp. 683. *Cratægus with obtuse, trifid, indented leaves.* *Mespilus Apii folio laciniato.* C. B. P. 453. Commonly called *L'Azarole.*

8. **CRATÆGUS** (*Oxyacantha*) foliis obtusis subtrifidis serratis. Hort. Cliff. 188. *Cratægus with obtuse, trifid, sawed leaves.* *Mespilus Apii folio, sylvestris spinosa*, sc. *oxyacantha.* C. B. P. 454. *The common White Thorn.*

9. **CRATÆGUS** (*Tomentosa*) foliis cuneiformi-ovatis serratis subangulatis subtus villosis ramis spinosis. Lin. Sp. 682. *Cratægus with oval, wedge-shaped, sawed, angular leaves, hoary on their under side, and prickly branches.* *Mespilus Virginiana grossulariæ foliis.* Pluk. Phyt. 100. f. 1.

The first sort grows naturally on the chalky hills in Kent, Surry, and Sussex, and in some other parts of England, and rises to the height of thirty or forty feet, with a large trunk, dividing upward into many branches; the young shoots have a brown bark, covered over with a mealy down, garnished with oval leaves between two and three inches long, and one and a half broad in the middle, of a light green on their upper side, but very white on their under, having many prominent transverse veins, running from the midrib to the border, where they are unequally sawed, some of the indentures being much deeper, and the segments broader than others. The flowers are produced at the ends of the branches in bunches, their foot-stalks being mealy, as are also the empalements of the flowers, which are cut into five obtuse segments, and are reflexed. The flowers have five short petals, which spread open like those of the Pear-tree, having a great number of stamina of the same length with the petals, terminated by oval summits. The germen, which is situated below the flowers, afterwards becomes an oval fruit, crowned with the empalement of the flower, having one cell, in which is inclosed three or four seeds. It flowers in May, and the fruit ripens in autumn.

This tree may be propagated by seeds, which should be sown soon after they are ripe; for if they are kept out of the ground till spring, they remain at least one year in the ground before the plants appear; so that the fruit should be buried in the ground, as is practised with the common Haws, Holly-berries, and those other hard seeds which do not come up the same year; and when the plants come up, they may be treated in the same manner as the Haws, but they should

should by no means be headed or cut down; when these plants are upon a poor chalky soil, they make great progress, and the wood is very white and hard, so has been often used for making cogs for mills, and many other purposes where hard tough timber is wanted.

It may also be propagated by layers in the same manner as the Lime-tree and Elm, but these should be laid in the young wood; but they are two years before they have sufficient roots to transplant. I have also raised a few plants from cuttings, which were planted in autumn, in a shady border, but there was not more than one eighth part of the cuttings which succeeded; therefore I would recommend the raising them from seeds, for the trees so raised grow much larger and straighter than those which are raised either from layers or cuttings.

The tree will take by grafting, or budding it upon Pear-stocks very well, and Pears will take by grafting upon these trees, so that there is a nearer affinity between the *Cratægus* and Pear, than there is between either of these and the *Mespilus*; for although both these will sometimes take upon the *Mespilus*, yet neither of them thrive so well, or last so long, when grafted, or budded upon those stocks, as they do upon each other; therefore Tournefort, who has joined the *Cratægus* in his section, with the Pear and Quince, has come nearer to the natural division of their genera, than those who have joined the *Cratægus* to the *Mespilus*.

There is another species of this tree which grows naturally about Verona, from whence I have received dried samples of it, but they were without flower and fruit, and came over by the same title as the former; for as there is no other growing in that neighbourhood, they have supposed it to be the common sort; but if that is the *Aria* of Theophrastus, those trees which grow in England are not, for the leaves of the sort from Verona are spear-shaped, and above an inch long, and not so broad by an inch as those of the English, and the nerves on the under side of the leaves are purplish, the leaves terminating in acute points, so that I make no doubt of its being a different species; but as I have not seen the growing tree, I would not enumerate it till I had been better informed.

The second sort grows naturally in many parts of England, and is chiefly found upon strong soils; it formerly grew in great plenty in Cane-Wood, near Hampstead; and lately there was some young trees growing in Bishop's-Wood, near the same place; but in many parts of Hertfordshire there are large trees now growing: this rises to the height of forty or fifty feet, with a large trunk, spreading at the top into many branches, so as to form a large head. The young branches are covered with a purplish bark, marked with white spots, and are garnished with leaves placed alternately, standing on pretty long foot-stalks; these are cut into many acute angles, like those of the Maple-tree; they are near four inches long, and three broad in the middle, having several smaller indentures toward the top, of a bright green on their upper side, but a little woolly on their under. The flowers are produced in large bunches toward the end of the branches, they are white, and shaped like those of the Pear-tree, but smaller, and stand upon longer foot-stalks; these appear in May, and are succeeded by roundish compressed fruit, which are shaped like large Haws, and ripen late in autumn, when they are brown; and if kept till they are soft, in the same way as Medlars, they have an agreeable acid flavour. The fruit of this tree is annually sold in the London markets in autumn.

The wood of this tree is hard, and very white, and is very useful for many purposes; but particularly so to the millwrights. It may be propagated in the same way as the former sort, but requires a strong soil.

The third sort grows naturally upon mount Baldus, from whence I received it, and on other mountainous

parts of Italy; this rises with a woody trunk about twenty feet high, dividing into many branches, which are covered with a purplish spotted bark, and closely garnished with oblong sawed leaves, standing alternate, on very short foot-stalks; they are about three inches long, and one and a half broad; in the broadest part, lessening toward both ends; they are slightly sawed on their edges, and of a deep green on both sides. The flowers are produced at the end of the branches in small bunches, which have rarely more than four or five flowers in each; they are white, and much smaller than those of the former sorts; these are succeeded by fruit about the size of the common Haw, which is of a dark brown colour when ripe. It flowers in May, and the fruit ripens in autumn.

The fourth sort is a native of North America, but has been many years cultivated in the English gardens, where it is known by the title of Cockspur Haw. Of this there are two species, one of which has no spikes on the branches; but the other has strong thorns which are curved downwards, greatly resembling the spur of a cock, from whence it had this appellation: in other respects both sorts agree in the form of their leaves, their flowers and fruit. However, Dr. Linnæus has been ill informed of the two sorts by Kalm, who went to America, and is now professor at Abo in Sweden; for the doctor has added the appellation of Cockspur to the fifth sort here mentioned, which has long been known in England by the title of Virginia L'Azarole.

The fourth sort rises to the height of near twenty feet in England, where the trunk becomes large, and divides into many strong branches, so as to form a large head; the leaves are large, oval, and deeply sawed on their edges, so as almost to divide them into lobes, which are placed without order; the flowers come out from the side of the branches in clusters; they are large, composed for the most part of five petals, which spread open, and are succeeded by pretty large Pear-shaped fruit of a scarlet colour. It flowers in May, and the fruit ripens in September.

The fifth sort is generally known by the title of Virginia L'Azarole; this rises with a strong stem to the height of fifteen feet or more, sending out many irregular branches covered with a light brown bark, and have a few thorns on their sides; the leaves have short foot-stalks, they are narrow at their base, but widen upward so as to become almost of an oval figure, of a lucid green on their upper side, and pretty deeply sawed on their edges; the flowers are white, pretty large, and composed of five petals which expand: these are succeeded by large fruit of a scarlet colour; it flowers the end of May, and the fruit ripens in September.

The sixth sort grows naturally in North America; this rises with a strong stem to the height of ten or twelve feet, sending out many strong irregular branches, which, while young, is covered with a bright brown bark, but that on the older branches is of a lighter colour; the leaves are oval, spear-shaped, slightly sawed on their edges, of a bright green on their upper side, but paler on their under; sometimes they are placed by pairs, at others three or four come out from the same joint; the flowers are produced in large clusters toward the end of the branches, forming a sort of corymbus, and are succeeded by roundish fruit of a middling size, and a deep red colour. As the branches of this sort shoot very strong, and are generally interwoven with each other, being armed with very long strong thorns, it is very proper for outward fences round gardens or fields.

The seventh sort grows naturally in Italy and the Levant, where the fruit is served up to table with their desert; this hath a strong stem rising twenty feet high, having many strong irregular branches, covered with a light-coloured bark; the leaves are in shape somewhat like those of the common Hawthorn, but they are much larger, have broader lobes, and are of a paler colour; the flowers come out in small clusters from the side of the branches, which are in

shape like those of the common Hawthorn, but are much larger; as is also the fruit, which when fully ripe has an agreeable acid taste, for which it is esteemed by the inhabitants of the countries where it grows naturally.

The eighth sort is the common Hawthorn, which is generally planted for fences in most parts of England, therefore being universally known to the inhabitants, it requires no description: there are two or three varieties of this sort, which differ in the size of their leaves and the strength of their shoots; however, those with the smallest leaves are generally preferred for hedges, as their branches always grow closer together; the method of raising the plants, and planting them for hedges, being fully treated of under the article of HEDGES, I need not repeat here.

The ninth sort grows naturally in North America, this has a slender shrubby stalk, rising about six or seven feet high, sending out many irregular branches, armed with long slender thorns, and garnished with short, oval, wedge-shaped leaves, which are sawed on their edges, and are woolly on their under side; the flowers are small, proceeding from the side of the branches, standing sometimes single, and at other times two or three upon the same foot-stalk, having large leafy empalements, and are succeeded by small roundish fruit, with a large leafy umbilicus, which was before the empalment of the flower: the flowers appear the beginning of June, and the fruit ripens very late in the autumn.

This sort may be propagated in the same manner as the first, but requires a strong deep soil, otherwise it will not thrive. It is very hardy in respect to cold, but at present is very rare in England.

All the sorts of Haws may be propagated by seeds, which should be sown in autumn, in the same manner as hath been directed for the first sort; but as these seeds are frequently brought from America, and do not arrive here till spring, the fruit may be buried in the ground till the autumn following, when they may be taken up and sown in drills, being careful to cover them so as to prevent birds from destroying them. In the spring following the plants will come up, which should be moderately watered two or three times a week, if the spring should prove dry; during the summer, they must be kept clean from weeds, which if suffered to grow, will soon overbear the plants and destroy them. The following spring the plants should be planted out before they begin to shoot, into a nursery-bed, where they may grow two years to get strength, when they may be transplanted where they are to remain. If these plants are planted in a moist light soil, their roots will extend to a considerable distance, and put up many shoots, which may be taken off in the spring, and thereby may be increased; this will also take if grafted on the Pear, and if the young branches are laid down, they will take root, so the plants may be propagated either way.

The other sorts of Hawthorn are generally planted among flowering shrubs of the same growth, where they add to the variety.

C R A T E V A. Lin. Gen. Plant. 528. *Tapia*. Plum. Nov. Gen. 22. tab. 21. Garlic Pear.

The CHARACTERS are,

The empalment of the flower is of one leaf, cut at the top into four oval segments, which spread open. The flower hath four oval petals, which are narrow at their base, and broad at the top. It hath many bristly stamina, which are longer than the petals, terminated by oblong erect summits. It hath a long incurved style, upon which sits the oval germen, crowned by the stigma, sitting close on the top. The germen afterward becomes a large fleshy globular fruit with one cell, including many kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnaeus's eleventh class, intitled Dodecandria Monogynia, the plants of this class and section have twelve stamina in their flowers, and one style.

The SPECIES are,

1. **C R A T E V A** (*Tapia*) *inermis foliis integerrimis, foliolis*

lateralibus basiantica brevioribus. Lin. Sp. 673. *Smooth Crateva, or Garlic Pear.* *Tapia arborea triphylla.* Plum. Nov. Gen. 22.

2. **C R A T E V A** (*Marmalos*) *spinosa foliis ferratis.* Flor. Zeyl. 212. *Prickly Crateva.* *Cucurbitifera trifolia spinosa medica, fructu pulpa Cydonii æmula.* Pluk. Alm. 125.

The first sort grows naturally in both Indies. I received the fruit of this from Jamaica, where it grows in great plenty, which were sent me by William Williams, Esq; of St. Anne's, in that island, who has been so kind as to furnish me with many other curious seeds which have succeeded in the Chelsea garden.

This tree hath a very large trunk, which rises to the height of thirty feet or upward, covered with a dark green bark, sending out many branches, so as to form a large head. The branches are garnished with trifoliate leaves, standing on pretty long foot-stalks; the middle leaf, which is much larger than either of the other, is oval, about five inches long, and two and a half broad in the middle. The two side leaves are oblique, those sides which join the middle leaf being much narrower than the other, and turn at both ends toward the middle, so that their midrib is not parallel to the sides; these two end in acute points. The leaves are smooth, of a light green on the upper side, but pale on their under; their edges are entire. The flowers are produced at the ends of the branches, standing upon long foot-stalks; these have empalements of one leaf, which are cut into four segments, almost to the bottom. The flower hath four oblong petals, which spread open, and are reflexed, having many long slender stamina, which are connected at their base, but spread open above, and are terminated by oblong purple summits; these surround a slender long style, upon which is situated the oval germen, which is crowned by an obtuse stigma. The germen afterward becomes a round fruit, about the size of an Orange, having a hard brown shell, or cover, inclosing a mealy pulp, filled with kidney-shaped seeds. This fruit hath a strong smell of Garlic, which is communicated to the animals that feed on it. This is propagated by seeds, which must be procured from the countries where the trees grow naturally, and must be sown on a hot-bed in the spring; when the plants come up, they must be treated in the same manner as hath been directed for the *ANNONA*, to which article the reader is desired to turn for the culture.

The second sort grows naturally in India, where it grows to a great height, with a large trunk, sending out many long branches, garnished with trifoliate leaves, which are oblong, entire, and end in acute points; between these the branches are armed with long sharp thorns, which come out by pairs, and spread asunder. The flowers are produced in small clusters from the side of the branches, five or seven standing upon a common branching foot-stalk; these have each five acute perals, which are reflexed, and many stamina which stand round a single style of the same length; the petals are green on the outside, whitish within, and have a grateful odour. After the flower is past, the germen swells to a large fruit the size of an Orange, having a hard shell, which incloses a fleshy viscous pulp, of a yellowish colour, having many oblong plain seeds situated within it; the pulp of this fruit hath an agreeable flavour when ripe, so is frequently eaten in India, where they serve up the fruit, mixed with Sugar and Orange, in their deserts, and is esteemed a great delicacy.

This sort is propagated by seeds, which must be procured from the places where it grows naturally; these must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot filled with light kitchen-garden earth, and plunged into a hot-bed of tanners bark, shading them every day from the sun, until they have taken fresh root, after which they may be treated in the same manner as the *ANNONA*; but

but should be sparingly watered in the winter season.

CREPIS. Lin. Gen. Plant. 819. Hieracioides. Vaill. Act. R. Sc. 1721. Hieracium. Tourn. Bastard Hawkweed.

The CHARACTERS are,

It hath a flower composed of many hermaphrodite florets, which are included in a double empalement; the outer is short, spreading, and falls off; the inner one is permanent, oval, and furrowed, having many narrow scales, which are contracted together at the top. The hermaphrodite florets are of one leaf; they are uniform, tongue-shaped, and are indented at the top in five parts; these spread over each other like the scales of fish; they have each five short hairy stamina, terminated by cylindrical summits. The germen is situated in the center of the florets, supporting a slender style, crowned by two reflexed stigmas. The germen afterward becomes an oblong seed, crowned with a long feathery down, which sits upon little foot-stalks.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Æqualis. The flowers of this section are composed of hermaphrodite florets, which are fruitful.

The SPECIES are,

1. CREPIS (*Rubra*) foliis amplexicaulibus, lyrato-runcinatis. Vir. Cliff. 79. *Crepis with lyre-shaped leaves embracing the stalks. Hieracium dentis leonis folio, flore suave rubente. C. B. P. 127. Hawkweed with a Dandelion leaf.*
2. CREPIS (*Barbata*) foliis pinnatis angulatis, petiolatis, dentatis. Prod. Leyd. 126. *Crepis with angular, indented, winged leaves, having foot-stalks. Hieracium foliis Cichorei sylvestris villosis, odore Castorei. Bot. Monsp.*
3. CREPIS (*Bætica*) involucris calyce longioribus incurvatis, foliis lanceolatis dentatis. *Crepis with an incurved volucrum longer than the empalement, and spear-shaped indented leaves. Hieracium medio-nigrum, Bæticum majus. Par. Bat. 185. Greater Spanish Hawkweed with flowers black in the middle.*
4. CREPIS (*Alpina*) foliis amplexicaulibus, oblongis, acuminatis inferioribus, supernè, summis infernè, denticulatis. Hort. Upsal. 238. *Crepis with oblong pointed leaves embracing the stalk, the lower being indented upward; and the upper downward. Hieracium Alpinum Scorzonera folio. Tourn. Inst. 472.*

There are several other species of this genus, some of which grow naturally in England, and others are weeds in divers parts of Europe, so are rarely admitted into gardens, therefore I shall not enumerate them here.

The first sort grows naturally in Apulia, but is now commonly cultivated in English gardens for ornament; it is an annual plant, which perishes after it hath ripened seeds. This hath many spear-shaped leaves which spread on the ground, deeply jagged on their sides; between them arise the branching stalks, which grow a foot and a half high, dividing into many slender branches, garnished with oblong leaves deeply indented on their edges, embracing the stalks with their base; the stalks are each terminated by one large radiated flower, of a soft red colour, composed of many half florets, which are succeeded by oblong seeds crowned with a feathery down. It flowers in June and July, and the seeds ripen in autumn. This plant, when bruised, emits an odour like bitter Almonds.

The seeds of this plant should be sown in the spring, on the borders of the flower-garden where they are designed to remain, so that if six or eight seeds are sown in each patch, when the plants come up, they may be reduced to three or four; and if these are kept clean from weeds, they will require no other culture, excepting the putting small sticks down, to fasten the stalks, to prevent their being broken by winds or rain. If the seeds are sown in autumn, or permitted to scatter, the plants will come up and live through the winter without shelter, and these will flower early in the spring.

The second sort grows naturally in the south of France, and in Italy. This is a biennial plant, and sometimes, when it is in poor ground, it will continue longer; it hath a thick tap-root, which strikes deep into the ground, sending out many small fibres; the lower leaves are from four to five inches long, and about a quarter of an inch broad, having several deep jags on their edges, the segments ending in acute points; from the same root arises four or five stalks, which grow about nine or ten inches high, the lower part of these are garnished with leaves of the same form with those near the root, but are smaller, and more jagged; the upper part of the stalks are naked, and branch out into two, and sometimes three branches, each being terminated by one flower of a gold colour, inclining to copper, composed of many florets which are included in a single empalement; the flowers are succeeded by oblong narrow seeds, crowned with a feathery down: the whole plant, when bruised, emits a strong odour of Castor. It flowers in June, and the seeds ripen in autumn. This is frequently preserved in gardens for the sake of variety.

It is propagated by seeds in the same manner as the first sort, but as this continues longer, the seeds need not be annually sown. The plants will require no other culture but to keep them clean from weeds, and if the seeds are permitted to scatter, the plants will come up without any trouble, so need only be thinned where they are too close.

The third sort is an annual plant, which grows naturally in Spain, but is now frequently propagated in the flower-gardens for ornament. This puts out leaves near the root, which are nine inches long, and almost two broad in the middle, of a light green colour, and a little jagged on their edges; the stalks rise a foot and a half high, dividing into many branches, garnished with leaves of the same form as those at bottom, but smaller, and sit close to the branches; the flowers are produced at the end of the branches; these have a double empalement, composed of many long very narrow leaves; the outer series are reflected downward, and turn upward again, and are inflexed at their extremities. The flowers are composed of many florets, which are stretched out on one side at the top like a tongue, these are cut at their extremities into four or five parts; they spread regularly in form of rays, and are situated over each other like scales of fish; there are two varieties of this, one with a deep yellow, and the other of a sulphur colour inclining to white; but both have a dark black bottom or middle, so make a pretty appearance in a garden. It flowers in June and July, and the seeds ripen in autumn. This plant requires the same culture as the first, and is equally hardy; so that where the seeds are permitted to scatter, the plants will come up without care.

The fourth sort grows naturally on the Alps; this is also an annual plant, which sends out many oblong pointed leaves near the root; they are five inches long, and almost two broad at their base, lessening gradually to a point; the upper part of these are slightly indented, but their lower parts are entire; the stalks are strong and upright, rising two feet high, dividing into three or four branches, which grow erect, and are terminated by pale white flowers, inclosed in a strong hairy empalement, which contracts close toward the top; the stalks are garnished with leaves of the same form as the lower, which embrace them with their base, where they are slightly indented, but their upper parts are entire; these leaves are hairy and rough. It flowers in June, and the seeds ripen in autumn. This requires the same culture as the first, and the seeds will scatter about the garden, so that if the plants are not destroyed, they will maintain themselves without any care.

CRESCENTIA. Lin. Gen. Plant. 680. Cujete. Plum. Nov. Gen. 23. tab. 16. Calabash-tree.

The CHARACTERS are,

The flower hath one petal, which is irregular, having a

curved gibbous tube, whose brim is cut into five unequal segments, which are reflexed; this hath an empalement, which is short, of one leaf, cut into two obtuse segments, which are concave. It hath four stamina, two of which are of the length of the petal; the other are shorter, terminated by twin summits which are prostrate. It hath an oval germen sitting on a foot-stalk, supporting a long slender style, crowned by a roundish stigma. The germen afterward becomes an oval or bottle-shaped fruit, with a hard shell, inclosing many flat heart-shaped seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia. The flower having two long and two short stamina, and the seeds being included in a capsule.

The SPECIES are,

1. CRESCENTIA (*Cujete*) foliis lanceolatis, utrinque attenuatis. Hort. Cliff. 327. *Crescentia with spear-shaped leaves, narrowed at both ends. Cujete foliis oblongis angustis magno fructu ovato. Plum. Nov. Gen. 23. Calabash-tree with oblong narrow leaves, and a large oval fruit.*
2. CRESCENTIA (*Latifolia*) foliis oblongo-ovatis, fructu rotundo, cortice fragili. *Crescentia with oblong oval leaves, and round fruit with a tender shell. Cujete latifolia, fructu putamine fragili. Plum. Nov. Gen. 23. Broad-leaved Calabash-tree whose fruit hath a tender shell.*

There are some varieties of these trees, which only differ in the size and shape of their fruit; but those are variations which arise from seeds of the same tree, so are not to be enumerated as distinct species; but the two here mentioned are undoubtedly different species, for I have frequently raised them from seeds, and have never found either of them vary.

The first sort grows naturally in Jamaica, and in all the Leeward Islands. This hath a thick trunk, covered with a whitish bark, which rises from twenty to thirty feet high, having several knots all the length, and at the top divides into many branches, which spread every way, and form a large regular head, garnished with leaves which come out irregularly; sometimes single, at others many arise from the same knot; they are near six inches long, and one and a half broad in the middle, diminishing gradually to both ends; they are of a lucid green, and have very short foot-stalks, with one midrib, and several transverse veins running from that to the sides. The flowers are produced from the side of the large branches, and sometimes from the trunk, standing upon long foot-stalks; their empalement is deeply divided into two obtuse segments. The flower hath but one petal, which is irregular, having an incurved tube, which is divided at the brim into two irregular segments, which turn backward; these are of a greenish yellow colour, striped and spotted with brown; the flowers are an inch and a half long, from the bottom of the tube to the extent of the upper segment. They have four slender stamina, of the same colour with the petal, which are of unequal lengths, two being full as long as the petal, and the other are much shorter, terminated by oblong summits, divided in the middle, which lie prostrate on the stamina. From the lower part of the tube arises a long slender foot-stalk, supporting the oval germen, which hath a headed stigma sitting close on the top; the germen afterward turns to a large fruit, of different forms and size; they are often spherical, sometimes they are oval, and at other times they have a contracted neck like a bottle; and are so large, as when the pulp and seeds are cleaned out, the shells will contain three pints or two quarts of liquid. These fruit or shells, are covered with a thin skin of a greenish yellow when ripe, which is peeled off; and under this is a hard ligneous shell, inclosing a pale, yellowish, soft pulp, of a tart unsavory flavour, surrounding a great number of flat heart-shaped seeds.

The shells of this fruit are cleaned of their pulp, and the outer skin taken off, by the inhabitants of the islands; and dried; then they use them for drink-

ing-cups, some of which are tipped with silver, and to the necks they fasten handles, and some of the long small fruit are formed into the shape of spoons or ladles, and are used as such; the round ones are cut through the middle, and are used as cups for Chocolate. The Indians put a number of small stones into these shells, when cleared of the pulp, to make a sort of rattle: in short, they convert these shells into many sorts of furniture, which is the principal use made of the fruit; for the pulp is seldom eaten, except by the cattle in the time of great droughts. The leaves and branches of this tree are also eaten by the cattle in times of scarcity. The wood of this tree is hard and smooth, so is frequently used for making saddles, stools, and other furniture.

The second sort seldom rises more than fifteen or twenty feet high; this hath an upright trunk, covered with a white smooth bark, sending out many lateral branches at the top, garnished with leaves three inches in length, and one and a quarter broad; these are ranged alternately on the branches, sitting upon short foot-stalks; they are of a deeper green than those of the first sort, and their edges are entire. The flowers come out from the side of the large branches and the trunk; these are smaller, and of a deeper yellow colour than those of the first; the fruit of this is sometimes round, at others oval, some being much larger than the other; the shells of this fruit are thin and very brittle, so are unfit for any purposes to which those of the former are employed; the seeds are also much thinner, and the pulp is of a deeper yellow. The wood of this tree is hard, and very white, so might be useful, were it not for the plenty of other sorts, which abound in many of the islands. This was found growing naturally in plenty at Campeachy by the late Dr. Houstoun, who sent the fruit to England.

These trees are too tender to live abroad in England, so require a warm stove to be preserved here. They are easily propagated by seeds, which must be procured from the countries where they grow naturally; the way is to have the entire fruit sent over when fully ripe; for when the seeds are taken out of the pulp abroad, and sent over hither, if they are long in their passage they will lose their growing quality before they arrive, as I have often experienced. These must be sown on a good hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a small halfpenny pot filled with light sandy earth, and plunged into a hot-bed of tanners bark, observing to shade them from the sun till they have taken fresh root; when they must be treated in the same manner as other tender plants, which are natives of the same countries. In winter they must be placed in the tan-bed of the bark-stove, and during that season should have but little water; in summer they will require to be gently watered two or three times a week, according to the warmth of the season; and in hot weather they should have a large share of air admitted to them. With this management the plants will make great progress, and their leaves being of a fine green, they make a pretty variety in the stove, but have not as yet flowered in England.

CRINUM. Lin. Gen. Plant. 366. Lilio-Asphodelus. Com. Rar. 14. Dillen. Hort. Elth. 194. Asphodel Lily.

The CHARACTERS are,

The involucre is composed of two oblong leaves, in form of a sheath or cover, which dries and is reflexed. The flower hath one petal, which is funnel-shaped, having a long tube, deeply cut at the top into six segments which are reflexed. It hath six long stamina, which are inserted in the tube of the petal, and are stretched out beyond the flower, spreading open; these are terminated by oblong prostrate summits, rising at one end; the germen is situated in

in the bottom of the flower, supporting a long slender style, crowned by a small trifid stigma. The germen afterward becomes an oval capsule with three cells, each containing one or two oval seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. CRINUM (*Africanum*) foliis sublanccolatis planis, corollis obtusis. Lin. Sp. Plant. 292. *Crinum with plain spear-shaped leaves, and obtuse petals.* Hyacinthus Africanus tuberosus, flore cæruleo umbellato. Hort. Amst. 1. p. 133, *African tuberous Hyacinth, with a blue umbellated flower.*
2. CRINUM (*Asiaticum*) foliis carinatis. Flor. Zeyl. 127. *Crinum with keel-shaped leaves.* Lilium Zeylanicum, bulbiferum & umbelliferum. H. L. 682.
3. CRINUM (*Americanum*) corollarum apicibus introrsum unguiculatis. Lin. Sp. Plant. 292. *Crinum with the tops of the petals formed on the inside like the nails of a finger.* Lilio-asphodelus Americanus sempervirens, maximus Polyanthus albus. Com. Rar. Pl. 15. tab. 15.
4. CRINUM (*Latifolium*) foliis ovato-lanceolatis acuminatis sessilibus planis. Lin. Sp. 419. *Crinum with oval, spear-shaped, plain leaves, ending in acute points.* Jovanna-pola-tali. Hort. Mal. vol. 11. p. 77.

The first sort grows naturally at the Cape of Good Hope, from whence it was brought to the gardens in Holland, and hath since been spread into most of the curious gardens in Europe. The root of this plant is composed of many thick fleshy fibres, diverging from the same head, which strike deep into the ground, and put out many smaller fibres, which are white and fleshy; from the same head arises a cluster of leaves surrounding each other with their base, so as to form a kind of herbaceous stalk, about three inches high, from which the leaves spread only two ways, appearing flat the other two. The flower-stalk arises by the side of these leaves, which is round, hollow, and near three feet high, terminated by a large head of flowers, included in a kind of sheath, which splits into two parts, and is reflexed. The flowers stand each upon a foot-stalk about one inch long; they are tubulous, have but one petal, which is cut almost to the bottom, into six oblong blunt segments, which are waved on their edges; in the center is situated an oval three-cornered germen, supporting a long style, which is attended by six stamina, two of the same length, two somewhat shorter, and the two which rest upon the lower segments are the shortest. The flowers are of a bright blue colour, and grow in large umbels, so make a fine appearance. They begin to flower in September, and frequently continue in beauty till spring, which renders them more valuable.

This plant is propagated by offsets, which come out from the side of the old plants, and may be taken off the latter end of June, at which time these plants are in their greatest state of rest; when the plants should be turned out of the pots, and the earth carefully cleared away from the roots, that the fibres of the offsets may be better distinguished, which should be separated from those of the old roots, being careful not to break their heads. But where they adhere so closely to the old plant, as not to be so separated, they must be cut off with a knife, taking great care not to wound or break the roots of either the offsets or the parent plant. When these are parted, they should be planted each into a separate pot, filled with light kitchen-garden earth, and placed in a shady situation, where they may enjoy the morning sun, giving them a little water twice a week, if the weather proves dry; but they must not have too much wet, especially at this season, when they are almost inactive; for as the roots are fleshy and succulent, they are apt to rot with great moisture. In about five weeks time the offsets will have put out new roots, when the pots may be removed to a more sunny situation, and then they may have a little more water, which will strengthen

their flowering, but it must not be given them too liberally for the reasons before given. In September they will put out their flower-stalks, and toward the end of that month the flowers will begin to open; when, if the weather should not be good, they should be removed under shelter, to prevent the flowers from being injured by frost or too much wet; but they should have as much free air as possible, otherwise the flowers will be pale-coloured and weak. Toward the end of October they should be removed into the green-house, and placed where they may enjoy as much free air as possible, and not be over-hung by other plants; and during the winter, they may have a little water once a week or oftener in mild weather, but in frost they should be kept dry. This plant only requires protection from frost and moisture, so should not have any artificial warmth in winter, and must be placed in the open air in summer.

The second sort hath large bulbous roots, which send out many large fleshy fibres, having bulbs formed at their ends; the leaves are near three feet long, hollow on their upper side, and closely fold over each other at their base, spreading out on every side; the outer leaves generally turn downward at the top; they are of a deep green, obtuse at their points, with a ridge on their under side. The flower-stalk arises on one side the leaves, which is thick, succulent, hollow in the middle, and a little compressed on two sides; this grows two feet high or more, and is of the same colour with the leaves, and are terminated by large umbels of flowers, with a sheath or cover, which splits lengthways, and reflexed back to the stalk, where it dries and remains; the tubes of the flowers are narrow, near four inches long, and the upper part is deeply cut into six long segments, which are reflexed back almost to the tube; in the center arises the style, attended by six long stamina, which stand out beyond the petal, and is terminated by oblong prostrate summits of a yellow colour. After the flowers are past, the germen, which is situated at the bottom of the tube, becomes a large, roundish, three-cornered capsule, having three cells, two of which are generally abortive, and the third hath one or two irregular bulbs, which if planted produce young plants.

The third sort hath broader leaves than the second, which are plain, and not hollowed on their upper side, but they are shorter and of a lighter green; these embrace each other at their base; by the side of these arise the flower-stalk, which is compressed and hollow, rising about two feet high, and terminated by large umbels of white flowers, like those of the former sort, but the segments of the petal are broader and not so much reflexed.

The fourth sort hath roots like those of the second sort; the leaves of this are narrower at their base, and are stained with purple on their under side; the flower-stalks are purple, and grow to the same height as those of the second; the flowers are in shape like them, but the tube is purple, and the segments have a purple stripe running through them; the stamina also are purple, which renders this more beautiful than either of the other sorts; and these differences are constant in all the plants which rise from seeds, so there can be no doubt of its being a distinct sort.

These three sorts grow naturally in both Indies, so are very tender, therefore must be kept in a warm stove, otherwise they will not thrive in England; they are easily propagated by offsets, which the roots put out in plenty; or by the bulbs which succeed the flowers, and ripen perfectly here. These must be planted in pots filled with rich earth, and if plunged into the tan-bed in the stove, the plants will make greater progress and flower oftener, than when they are placed on shelves; though in the latter way they will succeed very well, provided they are kept in a good temperature of heat. The roots should be transplanted in the spring, and all the offsets taken off, otherwise they will fill the pots and starve the old plants: they must be frequently refreshed with

water, but it must not be given them too plentifully, especially in winter. These sorts flower at every season of the year, which renders them more valuable; for where there are many plants, there will be almost a perpetual succession of flowers, which emit a very agreeable odour.

CRITHMUM. Lin. Gen. Plant. 303. Tourn. Inst. R. H. 317. tab. 169. Samphire.

The CHARACTERS are,

It is a plant with an umbelliferous flower; the great umbel is hemispherical, and composed of many smaller of the same figure; the involucre of the general umbel is composed of several spear-shaped leaves; those of the particular umbels have very narrow leaves the length of the umbel; the general umbel is uniform; the flowers have five oval inflexed petals, which are almost equal; they have five stamina the length of the petals, which are terminated by roundish summits. The germen is situated under the flower, supporting two reflexed styles, crowned by obtuse stigmas. The germen afterward becomes an oval compressed fruit, dividing into two parts, each having one compressed, elliptical, furrowed seed.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flowers having five stamina and two styles.

The SPECIES are,

1. **CRITHMUM** (*Maritimum*) foliolis lanceolatis carnosis. Hort. Cliff. 98. *Samphire with spear-shaped fleshy leaves.* Crithmum five Fœniculum maritimum minus. C. B. P. 288. *Samphire.*

2. **CRITHMUM** (*Pyrenaicum*) foliolis lateralibus bis trifidis. Hort. Cliff. 98. *Samphire whose smaller leaves on their sides are doubly trifid.* Apium Pyrenaicum thapsiæ facie. Tourn. Inst. 305.

The first sort grows upon the rocks by the sea-side, in many parts of England. This hath a root composed of many strong fibres, which penetrate deep into the crevices of the rocks, sending up several fleshy succulent stalks, which rise about two feet high, garnished with winged leaves, which are composed of three or five divisions, each of which hath three or five small, thick, succulent leaves near half an inch long; the foot-stalks of the leaves embrace the stalks at their base. The flowers are produced in circular umbels at the top of the stalks; these are of a yellow colour, composed of five petals, which are near equal in size, and are afterward succeeded by seeds somewhat like those of Fennel, but are larger. This herb is pickled, and esteemed very comfortable to the stomach, and is very agreeable to the palate; it provokes urine gently, removes the obstructions of the viscera, and creates an appetite; it is commonly used for sauce; it is gathered on the rocks where it grows naturally, but the people who supply the markets with it, seldom bring the right herb, but instead of it they bring a species of Aster, which is called golden Samphire, but hath a very different flavour from the true, nor has it any of its virtues. This grows in greater plenty, and upon the plain ground which is overflowed by the salt water; whereas, the true Samphire grows only out of the crevices of perpendicular rocks, where it is very difficult to come at. It flowers in July, and the seeds ripen in autumn.

This plant is with difficulty propagated in gardens, nor will it grow so vigorous with any culture, as it does upon rocks; but if the plants are planted on a moist gravelly soil, they will thrive tolerably well, and may be preserved some years. It may be propagated either by seeds or parting the roots.

The second sort is by Tournefort ranged in his genus of Apium. This grows naturally on the Pyrenean mountains. It is a biennial plant, which doth not flower till the second year, and perishes soon after the seeds are ripe. There are two or three sorts of this plant, which differ in their outer appearance, but I am not certain of their being distinct species. One of these is titled by Mr. Ray, Apium montanum five petræum album. This is of humbler growth than the other; the small leaves are broader, and not so much cut on their edges, and are of a paler green:

these plants are preserved in a few gardens for the sake of variety; they are propagated by seeds, which should be sown in the autumn where they are designed to remain, and will require no other culture but to keep them clean from weeds, and thin them where they are too close.

CRISTA GALLI. See **PEDICULARIS.**

CRISTA PAVONIS. See **POINCIANA.**

CROCUS. Lin. Gen. Plant. 53. Tourn. Inst. R. H. 350. tab. 183, 184. [is so called of the youth Crocus, who (as the poets feign) loved Smilax with so violent a passion, that, by reason of impatience, he was turned into a flower of his name.] Saffron.

The CHARACTERS are,

It hath a spathe or sheath of one leaf. The flower hath one petal, which is deeply cut into six oblong segments, which are equal. It hath three stamina which are shorter than the petal, terminated by arrow-pointed summits. The roundish germen is situated at the bottom of the tube, supporting a slender style, crowned by three twisted stigmas, which are sawed. The germen afterward becomes a roundish fruit, with three cells, filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's third class, intitled Triandria Monogynia, the flower having three stamina and one style.

The SPECIES are,

1. **CROCUS** (*Sativus*) spathâ univalvi radicali, corollæ tubo longissimo. Lin. Sp. Plant. 36. *Saffron with a spathe near the root, having one valve, and a long tube to the flower.* Crocus sativus. C. B. P. 65. *Cultivated Saffron.*

2. **CROCUS** (*Autumnalis*) spathâ univalvi pedunculato, corollæ tubo brevissimo. *Saffron with a spathe on the foot-stalk, having one valve, and a very short tube to the flower.* Crocus juncifolius autumnalis, flore magno purpurascens. Boerh. Ind. alt. 2. 120.

3. **CROCUS** (*Vernus*) spathâ bivalvi radicali, floribus sessilibus. *Crocus with a bivalve spathe near the root, and flowers sitting close to the ground.* Crocus vernus latifolius, flavo flore varius. C. B. P. 66. *Commonly called Bishop's Crocus.*

4. **CROCUS** (*Biflora*) spathâ biflorâ corollæ tubo tenuissimo. *Crocus with two flowers in each spathe, having very narrow tubes.* Crocus vernus, striatus, vulgaris. Par. Bat. *Ordinary, spring, striped Crocus.*

There are a much greater variety of these flowers than are here enumerated; but as most, if not all of them are only feminal variations, I thought it would be needless to particularize them here, especially as there are frequently new varieties obtained from seeds. Those which are here enumerated, I think must be allowed to be specifically different, since they have many distinguishing characters, which are sufficient to determine the specific difference in plants.

The first sort is the plant which produces the Saffron; which is a well known drug; this hath a roundish bulbous root as large as a small Nutmeg, which is a little compressed at the bottom, and is covered with a coarse, brown, netted skin; from the bottom of this bulb is sent out many long fibres, which strike pretty deep into the ground; from the upper part of the root come out the flowers, which, together with the young leaves, whose tops just appear, are closely wrapped about by a thin spathe or sheath, which parts within the ground, and opens on one side. The tube of the flower is very long, arising immediately from the bulb, without any foot-stalk, and at the top is divided into six oval obtuse segments, which are equal, of a purple blue colour. In the bottom of the tube is situated a roundish germen, supporting a slender style, which is not more than half the length of the petal, crowned with three oblong golden stigmas (which is the Saffron;) these spread alunder each way. The style is attended by three stamina, whose bases are inserted in the tube of the petal, and rise to the height of the style, where they are terminated by arrow-pointed summits. This plant flowers in October, and the leaves keep growing all the winter, but it never produces any seeds here.

The

The second sort grows naturally on the Alps and Helvetian mountains: this hath a smaller bulbous root than the first, which is more compressed; the flowers appear about the same season with the former, but they rise with a short foot-stalk, having a short spatha or sheath just below the flower, which covers it before it expands. The tube of the flower is very short, the petal being divided almost to the bottom, and the segments terminate in acute points; the stamina and style are short, and the leaves of the plant are very narrow. The flower is of a deep blue; but there is a variety of this with a sky blue flower, which is supposed to have been produced by seeds. Dr. Linnæus has supposed these, and also all the varieties of the Spring Crocus, to be but one species, but there can be no doubt of these being distinct from those of the Spring.

The third sort hath a pretty large, compressed, bulbous root, covered with a light, brown, netted skin, from which arise four or five leaves, like those of the other Vernal Crocuses, of a purplish colour on their lower parts; from between these come out one or two flowers of a deep yellow colour, sitting close between the young leaves, never rising above two inches high; these have an agreeable odour; the outer segments of the petal are marked with three black streaks or stripes running lengthways from the bottom to the top of the segment; these are narrower than the inner segments. From the double arrangement of these segments some have called it a double flower. These segments have dark purple bottoms, and the tube of the flower hath as many purple stripes as there are segments in the petal. Out of the center of the tube arises a slender style, crowned by a golden stigma, which is broad and flat, and is attended by three slender stamina of the same length, terminated by yellow summits. After the flower is past, the germen pushes out of the ground, and swells to a roundish three-cornered seed-vessel, which opens in three parts, and is filled with roundish brown seeds. This is one of the earliest Crocuses in the spring.

The fourth sort rises with a few very narrow leaves, which are, together with the flower-buds, closely wrapped round by a spatha or sheath, out of which arise two flowers, one of which hath a longer tube than the other, but these are very slender, and do not rise much above the spatha; there the petal enlarges, and is divided into six obtuse segments, which are of equal size; they are of a dirty white on their outside, with three or four purple stripes in each; the inside of the petal is of a purer white; the stamina and style are nearly the same as those of the former sort. This is one of the earliest sorts which flowers in the spring.

The VARIETIES of the autumnal Crocus are,

1. The sweet-smelling autumnal Crocus, whose flowers come before the leaves. C. B. This is our second sort.
2. The autumnal mountain Crocus. C. B. This hath a paler blue flower.
3. The many flowering bluish autumnal Crocus. C. B. This hath many sky blue flowers.
4. The small flowering autumnal Crocus. C. B. This hath a small deep blue flower.

The VARIETIES of the Spring Crocus are,

1. Broad-leaved, purple, variegated, Spring Crocus. C. B. This hath broad leaves and a deep blue flower striped.
2. Broad-leaved Crocus of the spring with a purple flower. C. B. This hath a plain purple flower.
3. Broad-leaved Spring Crocus with a Violet-coloured flower. C. B. This hath a large deep blue flower.
4. Spring Crocus, with a white flower and a purple bottom. C. B.
5. Broad-leaved, white, variegated, Spring Crocus. C. B.
6. Broad-leaved Spring Crocus, with many purple Violet flowers striped with white. C. B.
7. Broad-leaved Spring Crocus with an Ash-coloured flower.

8. Broad-leaved Spring Crocus with a large yellow flower. C. B.

9. Broad-leaved Spring Crocus with a smaller and paler yellow flower. C. B.

10. Broad-leaved Spring Crocus, with smaller yellow flowers striped with black.

11. Narrow-leaved Spring Crocus with a smaller brimstone-coloured flower.

12. Narrow-leaved Spring Crocus with a small white flower.

These are the principal varieties which I have observed in the English gardens, but there are many more mentioned in the foreign catalogues of flowers, many of which are so nearly alike, as scarce to be distinguished; and if the seeds of these flowers were sown, there might be a greater variety of them obtained than is at present; but as they propagate very fast by offsets, the seeds are very rarely regarded.

All these several varieties of Crocuses are very hardy, and will increase exceedingly by their roots, especially if they are suffered to remain two or three years unremoved; they will grow in almost any soil or situation, and are very great ornaments to a garden early in the spring of the year, before many other flowers appear. They are commonly planted near the edges of borders on the sides of walks; in doing of which, you should be careful to plant such sorts in the same line as flower at the same time, and are of an equal growth, otherwise the lines will seem imperfect. These roots, losing their fibres with their leaves, may then be taken up, and kept dry until the beginning of September, observing to keep them from vermin, for the mice are very fond of them. When you plant these roots (after having drawn a line upon the border,) make holes with a dibble about two inches deep or more, according to the lightness of the soil, and two inches distance from each other, in which you must place the roots with the bud uppermost; then with a rake fill up the holes in such a manner as that the upper part of the root may be covered an inch or more, being careful not to leave any of the holes open; for this will entice the mice to them, which, when once they have found out, will destroy all your roots, if they are not prevented.

This is the way in which these flowers are commonly disposed in gardens, but the better way is to plant them six or eight near each other in bunches between small shrubs, or on the borders of the flower-garden; where, if the varieties of these flowers are planted in different patches, and properly intermixed, they will make a much better appearance than when they are disposed in the old method of strait edgings.

In January, if the weather is mild, the Crocus will often appear above ground; and in February their flowers will appear, before the green leaves are grown to any length, so that the flower seems at first to be naked; but soon after the flowers decay, the green leaves grow to be six or eight inches long, which should not be cut off until they decay, notwithstanding they appear a little unsightly; for by cutting off the leaves, the roots will be so weakened as not to arrive at half their usual bigness, nor will their flowers the succeeding year be half so large. Their seeds are commonly ripe about the latter end of April, or the beginning of May, when the green leaves begin to decay.

The autumnal Crocuses are not so great increasers as are those of the spring, nor do they produce seeds in our climate; so that they are less common in the gardens, except the true Saffron, which is propagated for use in great plenty in many parts of England; these must be taken up every third year, as was directed for the Spring Crocuses, otherwise the roots will run long, and produce no flowers; but they should not be kept out of the ground longer than the beginning of August, for they commonly produce their flowers the beginning of October; so that if they remain too long out of the ground, they will not produce their flowers so strong, nor in such plenty, as when they are planted early.

The

The method of cultivating Saffron being somewhat curious, I thought it not improper to insert in this place an abstract of it, as it was presented to the Royal Society by Dr. James Douglass.

As Saffron grows at present most plentifully in Cambridgeshire, and has grown formerly in several other counties of England, the method of culture does not, I believe, vary much in any of them, and therefore I judge it sufficient to set down here the observations which I employed proper persons, in different seasons, to make, in the years 1723, 1724, 1725, and 1728, up and down all that large tract of ground that lies between Saffron-Walden and Cambridge, in a circle about ten miles diameter.

In that county Saffron has been cultivated, and therefore it may be reasonably expected, that the inhabitants thereof are more thoroughly acquainted with it than they are any where else.

I shall begin with the choice and preparation of the ground. The greatest part of the tract already mentioned is an open level country, with few inclosures; and the custom there is, as in most other places, to crop two years, and let the land be fallow the third. Saffron is generally planted upon fallow ground, and, all other things being alike, they prefer that which has borne Barley the year before.

The Saffron grounds are seldom above three acres, or less than one; and in choosing, the principal thing they have regard to is, that they be well exposed, the soil not poor, nor a very stiff clay, but a temperate dry mould, such as commonly lies upon chalk, and is of an Hazel colour; though if every thing else answers, the colour of the mould is pretty much neglected.

The ground being made choice of, about Lady-Day, or the beginning of April, it must be carefully ploughed, the furrows being drawn much closer together, and deeper, if the soil will allow it, than is done for any kind of corn; and accordingly, the charge is greater.

About five weeks after, during any time in the month of May, they lay between twenty and thirty loads of dung upon each acre, and having spread it with great care, they plough it in as before. The shortest rotten dung is the best; and the farmers, who have the conveniency of making it, spare no pains to make it good, being sure of a proportionable price for it. About Midsummer they plough a third time, and between every sixteen feet and an half, or pole in breadth, they leave a broad furrow or trench, which serves both as a boundary to the several parcels, when there are several proprietors to one inclosure, and to throw the weeds in at the proper season.

To this head likewise belongs the fencing of the grounds, because most commonly, though not always, that is done before they plant. The fences consist of what they call dead hedges, or hurdles, to keep out not only cattle of all sorts, but especially hares, which would otherwise feed on the Saffron leaves during the winter.

About the weather we need not only observe, that the hottest summers are certainly the best, and therewith, if there be gentle showers from time to time, they can hardly miss of a plentiful crop, if the extreme cold, snow, or rain of the foregoing winter have not prejudiced the heads.

The next general part of the culture of Saffron is, planting, or setting the roots; the only instrument used for which is a narrow spade, commonly termed a spit shovel.

The time of planting is commonly in the month of July, a little sooner or later, according as the weather answer. The method is this: one man with his spit shovel raises between three and four inches of earth, and throws it before him about six or more inches; two persons, generally women, following with heads, place them in the farthest edge of the trench he makes, at three inches distance from each other, or thereabouts; as soon as the digger or spitter has gone once the breadth of the ridge, he begins again at the

other side, and digging as before, covers the roots last set; and makes the same room for the setters to place a new row, at the same distance from the first, that they are from one another. Thus they go on, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave some part of the first stratum of earth untouched, to lie under the roots, and, in setting, to place the roots directly upon their bottom.

What sort of roots are to be preferred shall be shewn under the fourth head, but it must be observed in this place, that formerly, when roots were very dear, they did not plant them so thick as they do now; and that they have always some regard to the size of the roots, placing the largest at a greater distance than the small ones.

The quantity of roots planted in an acre, is generally about 16 quarters, or 128 bushels, which, according to the distances left between them, as before assigned, and supposing all to be an inch in diameter one with another, ought to amount to 392,040 in number.

From the time that the roots are planted, till about the beginning of September, or sometimes later, there is no more labour about them; but as they then begin to spire, and are ready to shew themselves above ground (which is known by digging a few out of the earth,) the ground must be carefully pared with a sharp hoe, and the weeds, &c. raked into the furrows, otherwise they would hinder the growth of the plants.

In some time after appear the Saffron flowers, and this leads us to the third branch of our present method. The flowers are gathered as well before as after they are full blown, and the most proper time for this is early in the morning. The owners of the Saffron get together a sufficient number of hands, who place themselves in different parts of the field, who pull off the whole flowers, and throw them handful by handful into a basket, and so continue till all the flowers are gathered, which happens commonly about ten or eleven o'clock.

Having then carried home all they have got, they immediately spread them upon a large table, and fall to picking out the filamenta styli, or chives, and together with them a pretty long proportion of the stylus itself, or string to which they are joined; the rest of the flower they throw away as useless. The next morning they return into the field again, whether it be wet or dry weather, and so on daily, even on Sundays, till the whole crop be gathered.

The chives being all picked out of the flowers, the next labour about them is to dry them on the kiln. The kiln is built upon a thick plank (that it may be moved from place to place) supported by four short legs; the outside consists of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches square at the bottom on the inside, and twenty-two inches at top, which is likewise equal to the perpendicular height of it. On the fore-side is left a hole about eight inches square, and four inches above the plank, through which the fire is put in; over all the rest laths are laid pretty thick, close to one another, and nailed to the frame already mentioned, and then are plaistered over on both sides, as are also the planks at bottom very thick, to serve for a hearth. Over the mouth, or widest part, goes a hair cloth, fixed to the sides of the kiln, and likewise to two rollers, or moveable pieces of wood, which are turned by wedges or screws, in order to stretch the cloth. Instead of the hair cloth, many people now use a net-work, or iron wire, with which it is observed that the Saffron dries sooner, and with less quantity of fuel; but the difficulty in preserving the Saffron from burning, makes the hair cloth be preferred by the nicest judges in drying.

The kiln is placed in a light part of the house, and they begin by laying five or six sheets of white paper on the hair cloth, upon which they spread the wet Saffron between two and three inches thick; this they cover

cover with other sheets of paper, and over these lay a coarse blanket five or six times doubled; or, instead thereof, a canvas pillow filled with straw; and after the fire has been lighted for some time, the whole is covered with a board, having a large weight upon it.

At first they give it a pretty strong heat, to make the chives sweat (as their expression is;) and in this, if they do not use a great deal of care, they are in danger of scorching, and so of spoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the Saffron off from that which lies next it, raising at the same time the edges of the cake with a knife; then laying on the paper again, they slide in another board between the hair cloth and upper papers, and turn both papers and Saffron upside-down, afterwards covering them as above.

The same heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it; then they cover it, and lay on the weight as before. If nothing happens amiss during these first two hours, they reckon the danger to be over; for they have nothing more to do but to keep a gentle fire, and to turn their cakes every half hour till thoroughly dry, for the doing of which as it ought, there are required full twenty-four hours.

In drying the larger plump chives they use nothing more, but towards the latter end of the crop, when these come to be smaller, they sprinkle the cake with a little small beer, to make it sweet as it ought; and they begin now to think, that using two linen cloths next the cake, instead of the two innermost papers, may be of some advantage in drying, but this practice is followed as yet but by few.

Their fire may be made of any kind of fuel, but that which smokes the least is best, and charcoal, for that reason, is preferred to any other.

What quantity of Saffron a first crop will produce, is very uncertain; sometimes five or six pounds of wet chives are got from one rood, sometimes not above one or two, and sometimes not enough to make it worth while to gather and dry it; but this is always to be observed, that about five pounds of wet Saffron go to make one pound of dry, for the first three weeks of the crop, and six pounds during the last week; and when the heads are planted very thick, two pounds of dried Saffron may, at a medium, be allowed to an acre for the first crop, and twenty-four pounds for the two remaining, the third being considerably larger than the second.

In order to obtain these, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the same manner as before set down, without the addition of any thing new, except that they let cattle into the fields, after the leaves are decayed, to feed upon the weeds, or, perhaps, mow them for the same use.

About the Midsummer after the third crop is gathered, the roots must be all taken up and transplanted; the management requisite for which, is the fourth thing to be treated of. To take up the Saffron heads, or break up the ground (as the term is,) they sometimes plough it, sometimes use a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over; during all which time of ploughing, or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads as they are turned up.

They are next to be carried to the house in sacks, and there cleaned and rased; this labour consists in cleaning the roots thoroughly from earth, and from the remains of old roots, old involucre, and excrescences, and thus they become fit to be planted in new ground immediately, or to be kept for some time without danger of spoiling.

The quantity of roots taken up, in proportion to those which were planted, is uncertain; but at a medium, it may be said, that allowing for all the accidents which happened to them in the ground, and in

breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are sure to choose for their own use the largest, plumpest, and fattest roots, but do least of all approve the longest pointed ones, which they call spickets, or spickards, for very small, round, or flat roots, are sometimes observed to flower well.

This is the whole culture of Saffron in the county above-mentioned, and we have only now to consider the charges and profits which may be supposed; one year with another, to attend that branch of agriculture; and of these I have drawn up the following computation for one acre of ground, according to the price of labour in this country.

	l.	s.	d.
Rent for three years — — —	3	0	0
Ploughing for three years — — —	0	18	0
Dunging — — — — —	3	12	0
Hedging — — — — —	1	16	0
Spitting and setting the heads — —	1	12	0
Weeding or paring the ground — —	1	4	0
Gathering and picking the flowers —	6	10	0
Drying the flowers — — — — —	1	6	0
Instruments of labour for three years, } with the kiln, about — — —	0	10	0
Ploughing the ground once, and har- } rowing twice — — — — —	0	12	0
Gathering the Saffron heads — — —	1	0	0
Raising the heads — — — — —	1	12	0
Total charge	23	12	0

This calculation is made upon supposition, that an acre of ground yields twenty-six pounds of nett Saffron in three years, which I stated only as a mean quantity between the greatest and the least, and therefore the price of Saffron must be judged accordingly, which I think cannot be done better than by fixing it at 30 shillings per pound; since in very plentiful years it is sold at twenty, and is sometimes worth between three and four pounds; at this rate, twenty-six pounds of Saffron are worth thirty-nine pounds, and the nett profits of an acre of ground producing Saffron, will, in three years, amount to fifteen pounds, thirteen shillings, or about five pounds four shillings yearly.

This, I say, may be reckoned the nett profit of an acre of Saffron, supposing that all the labour were to be hired for ready money; but as the planter and family do a considerable part of the work themselves, some of this expence is saved; that is, by planting Saffron, he may not only reasonably expect to clear about five pounds yearly per acre, but also to maintain himself and family for some part of each year; and it is upon this supposition only, that the result of other computations can be said to have any tolerable degree of exactness, but the calculations themselves are undoubtedly very inaccurate.

I have said nothing here concerning the charge in buying, or profits in selling, the Saffron heads, because, in many large tracts of ground, these must at length balance one another, while the quantity of ground planted yearly continues the same, which has been pretty much the case for several years past.

Dr. Patrick Blair, designing to treat concerning the Crocus, in his sixth Decad of his Pharmaco-Botanologia, did, in the year 1725, send to me the following queries:

1. After what manner the species are propagated?
2. Whether the tap-root springs first, or the bulb?
3. At what season the leaves spring forth?

To these queries I sent him the following answer:

1. As to the propagation of the species.

This is only by the roots or offsets, which the old roots produce in great plenty, for I never saw any thing like a seed, or a seed-vessel produced, though I have let stand great quantities of flowers purposely to try.

2. As to the query, Whether the tap-root springs first, and the bulb be afterwards formed?

4 M

As

As soon as the roots begin to shoot upwards, there are commonly two or three large tap-roots sent forth from the side of the old root, which will run down-right two inches and a half or more, into the ground; at the place where these bulbs first come out from the old one, will be formed a bulb sometimes (though not always, as you will hear presently;) and this tap-root decays. The bulb will increase in its bigness, till at last it quite falls off, and is then left entire, which commonly happens in April, when the green begins to decay; but many times these tap or carrotty roots never produce any bulbs, but always retain the same figure, and for ever after, I believe are barren; for I planted a parcel of these carrotty roots four years ago in a little bed, where they have ever since remained, but have not produced one single flower, notwithstanding they have produced a numerous offspring of the same carrotty roots.

And the people about Saffron Walden are well apprised of this barrenness, and therefore throw away all such roots when they make a new plantation; but as this change of the root is not peculiar to the Saffron only, permit me to digress a little, to give you some account of this matter.

In the parish of Fulham, near London, the gardeners used to drive a great trade in the Jonquil, or Narcissus juncifolius, flore multiplici, at which place the greatest quantity of those roots was raised for sale, as perhaps was in any part of England, and turned to as great account for the master, as any crop they could employ their ground in, till of late years, that most of their roots have turned carrotty, and so proved barren, or have produced only single flowers; so that the gardeners being hereby disheartened, have thrown them out entirely, neglecting to cultivate them, satisfying themselves with this reason, that their ground was tired with them.

But to return to the Crocus. Besides those roots already mentioned, there will be three or four small bulbs formed upon the upper part of the root, and some underneath, which from the first appearance assume the round shape of its parent root, and have no tap-root belonging to them; those on the upper part of the root rarely emit so much as a fibre, but receive their nourishment immediately from the old root; but those on the under side send out many fibres all around, by which they draw their nourishment from the ground; these being parted from the old root much sooner than the other, stand in need of fit organs for receiving their nourishment.

I have sometimes taken up some, through the middle of which hath been a root of the Gramen caninum, or Couch Grass, which some people have imagined had strength enough to force its way through the Crocus root; but the truth is, the root of the Grass closely adhering to the old root of the Crocus, just at the place where the young roots were emitted, these young roots being quick of growth, inclosed the root of the Grass, and thus I have seen several roots run through each other in the same manner.

But besides these offsets mentioned, directly upon the upper part of the root is one large root formed, of equal bigness with the old one, and this is the time that the root is Radix gemina, as Tournefort calls it; for they are not so at any other season, and therefore I think it a very improper appellation; for when the new roots are perfectly formed, the old ones, with their coats, fall off and die, and leave the new roots all single. This has occasioned several people to doubt of what Tournefort had said of the roots, till I took up some plants at that season, and with them the two roots of equal bigness, i. e. the old at the bottom, and the new one at the top.

Dr. Blair also happening, in viewing a root, to be surprised with a different appearance from what he had seen before or heard of, sent me another letter.

The manner of the root was thus; from the upper part of the bulb, where it sends forth all the leaves within a common tunicle, at the exit there was an appendix about an inch and a half long, about the gross-

ness of a large turkey or goose-quill, cylindrical and blunt, without the least radical fibre, by which it might receive the nourishment, smooth or polished, and bluish in the surface, consisting of several circular lines, when cut transversely; white, with a hard greenish center like a Carrot, when it hath pushed forth the flowering-stem, not unlike the stolones of some running root, such as the Mints below ground, only the extremity descended obliquely, instead of ascending, to send forth leaves to produce a new plant; and what is most remarkable, this did not happen to one or two plants, but to the whole bundle, which were above twenty distinct roots, differing in nothing but majus and minus; the bulb seemed at the same time to be pined and emaciated, though it emitted large radical fibres like those of a Leak.

I having received this account from him by letter, sent him the following answer:

I received yours in answer to my last, with the figure of the roots of some sets of Crocus Aurumnalis you have taken out of the ground; I have found a figure in Dodonæus which corresponds with it, and those roots are no new thing with the Saffron gardeners, who always throw them away when they make fresh plantations.

Your figure does not agree with my tap-roots, as you will see by the figure taken as just from the life as I could. In mine you will find the bulb turned sideways, which I still find to be constant in all the roots I have examined, which have been a great many, and makes me suspect these tap-roots are occasioned by the accidental position of the roots in planting, which may retard the ascending sap, the flowering-stem being thereby turned into a crooked figure, and the tap-roots are full of longitudinal vessels, of a considerable dimension; so that the greater attracting power of the sap being hereby diverted downwards, the flower-stem may be quite destitute of proper nourishment.

The method you propose to remedy this inconvenience, will not do, for I have removed some of these roots at the season when the tap-roots were forming, and this alone destroyed them all; so that I am persuaded, the cutting them off entirely will kill them.

The method I used with the Jonquils was, to lay some tiles just under the roots, to prevent their running downwards, but this has not answered, nor do I think it possible wholly to recover them; for the alteration is not only in the root and flower, but also in the leaf and blade, which before was fistulous, but after this alteration in the root, becomes a plain sulcated leaf, and if it ever blossoms after, the flowers are large and single, which before were small and double; but the Saffron, after the change of its roots, produces a small narrow blade, seldom half the length of those in a natural state.

Upon this Dr. Blair formed this conclusion:

These additional observations plainly shew, that neither the carrotty root, nor the blasted tap-root, as I may call it, are merely accidental, or what may be called lusus naturæ, but certain diseases incident to such roots; for were they accidental, they would not have the same appearances to different persons in different soils and climates, nor would so many taken up together have such a resemblance to each other, as I have twice observed.

CROTOLARIA. Lin. Gen. Plant. 771. Dill. Elth. 122. Tourn. Inst. R. H. 644. [of Κρόταλον, Gr. rattle; because its seeds in the pods, when ripe, make a rattling noise when shaken, or because the infants of the Indians make use of the branches of this plant furnished with pods instead of rattles.]

The CHARACTERS are,

The empalement of the flower is divided into three large segments; the two upper resting on the standard, the lower is concave, trifid, and is situated below the keel. The flower is of the Butterfly-kind; the standard is large, heart-shaped and pointed; the wings are oval and half the length of the standard; the keel is pointed and as long as the wings; it hath ten stamina which are united, terminated

minated by single summits, and an oblong reflexed germ, supporting a single style, crowned by an obtuse stigma. The germ afterward becomes a short turgid pod with one cell, opening with two valves, and filled with kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria the flowers of this class and section having ten stamina joined in two bodies.

The SPECIES are,

1. CROTOLARIA (*Verrucosa*) foliis simplicibus ovatis, stipulis lunatis declinatis ramis tetragonis. Flor. Zeyl. 277. *Crotolaria* with single oval leaves, lunated declining stipulæ, and four-cornered branches. *Crotolaria* Asiatica folio singulari verrucoso, floribus cæruleis. H. L. 199.
2. CROTOLARIA (*Pilosa*) foliis simplicibus lanceolatis pilosis, petiolis decurrentibus. *Crotolaria* with single, hairy, spear-shaped leaves, and running foot-stalks. *Crotolaria* Americana, caule alato foliis pilosis, floribus in thyrsis luteis. Martyn. Cent. 43.
3. CROTOLARIA (*Sagittalis*) foliis simplicibus lanceolatis stipulis foliariis decurrentibus bidentatis. Hort. Cliff. 357. *Crotolaria* with single spear-shaped leaves, and single stipulæ indented. *Crotolaria* hirsuta minor Americana herbacea, caule ad summum sagittato. H. L. 202.
4. CROTOLARIA (*Fruticosa*) foliis simplicibus, linearilanceolatis hirsutis, petiolis decurrentibus, caule fruticoso. *Crotolaria* with single, narrow, spear-shaped leaves, which are hairy, running foot-stalks, and a shrubby stalk. *Crotolaria* frutescens hirsuta, flore luteo, ramulis alatis, foliis mucronatis. Houst. MSS.
5. CROTOLARIA (*Juncea*) foliis simplicibus lanceolatis, petiolatis caule striato. Hort. Cliff. 357. *Crotolaria* with single spear-shaped leaves having foot-stalks. *Crotolaria* Benghalensis foliis genistæ hirsutis. Pluk. Alm. 121.
6. CROTOLARIA (*Perfoliata*) foliis perfoliatis cordato-ovatis. Lin. Sp. Plant. 1005. *Crotolaria* with oval heart-shaped leaves perforated by the stalks. *Crotolaria* perfoliatæ folio. Hort. Elth. 122. tab. 102.
7. CROTOLARIA (*Retusa*) foliis simplicibus, oblongis cuneiformibus retusis. Flor. Zeyl. 276. *Crotolaria* with single, oblong, wedge-shaped leaves, reflexed at the top. *Crotolaria* Asiatica, floribus luteis, folio singulari cordiformi. H. L. 200.
8. CROTOLARIA (*Villosa*) foliis simplicibus ovatis villosis, petiolis simplicissimis, ramis teretibus. Hort. Cliff. 357. *Crotolaria* with single, oval, hairy leaves, single pedicles and taper branches. *Crotolaria* arborescens Africana, Styracis folio. H. L. 170.
9. CROTOLARIA (*Angulata*) foliis ovatis sessilibus, ramulis angulatis hirsutis, floribus lateralibus simplicissimis. *Crotolaria* with oval leaves sitting close to the branches, which are angular, hairy, and single flowers proceeding from the sides of the branches.
10. CROTOLARIA (*Laburnifolia*) foliis ternatis ovatis acuminatis, stipulis nullis, leguminibus pedicellatis. Flor. Zeyl. 278. *Crotolaria* with oval, trifoliate, pointed leaves, no stipulæ, and foot-stalks to the pods. *Crotolaria* Asiatica frutescens, floribus luteis amplis trifoliata. H. L. 196.
11. CROTOLARIA (*Alba*) foliis ternis lanceolato-ovatis, caule lævi herbaceo, racemo terminali. Hort. Cliff. 499. *Crotolaria* with oval, spear-shaped, ternate leaves, smooth herbaceous stalks, which are terminated by loose spikes of flowers. *Anonis* Caroliniana perennis non spinosa, foliorum marginibus integris, floribus in thyrsis candidis. Martyn. Cent. 44.

The first sort grows naturally in India. This is an annual plant, which hath an herbaceous four-cornered stalk, rising about two feet high, dividing into three or four branches; these have also four acute angles, and are garnished with oval warted leaves, of a pale green colour, standing on very short foot-stalks; the flowers are produced in spikes at the end of the branches, which are of the butterfly shape, and of a light blue colour, succeeded by short turgid pods, which inclose one row of kidney-shaped

seeds. It flowers in July and August, and the seeds ripen in autumn.

This plant is propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are come up an inch high, they should be transplanted to another hot-bed to bring them forward, observing to shade them from the sun till they have taken new root; after which they should have free air admitted to them in proportion to the warmth of the season, to prevent their being drawn up weak. When the plants have acquired strength in this bed, they should be carefully taken up, with balls of earth to their roots, and each planted in a separate pot, filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, carefully shading them till they are rooted again; then they must be treated in the same manner as other tender exotic plants, giving them proper air and water in warm weather; when the plants are grown so tall as to nearly reach the glasses of the hot-bed, the pots may be removed into an airy glass-case, or stove, where they may be screened from inclement weather, and have proper air in hot weather; with this treatment the plants will flower in July, and continue to produce fresh spikes of flowers till the end of August; and those spikes of flowers which appear early in the season, will be succeeded by ripe seeds in September, soon after which the plants will decay.

The second sort grows naturally at La Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houstoun; this rises with a compressed winged stalk near three feet high, putting out several side branches, garnished with spear-shaped leaves near three inches long, and one broad, covered with soft hairs, and sit close to the branches, alternately; from the foot-stalks of each there runs a border or leafy wing, along both sides of the branches; the flowers are produced in loose spikes at the end of the branches, which are of a pale yellow colour, the standard being stretched out a considerable length beyond the wings. These are succeeded by short turgid pods, which, when ripe, are of a deep blue colour, having one row of small kidney-shaped seeds, which are of a greenish brown colour. This flowers and seeds about the same time with the former, and requires the same treatment.

The third sort was sent me from South Carolina by the late Dr. Dale, and also from Jamaica by Dr. Houstoun, so that it grows naturally in several parts of America; this is an annual plant, which rises with a slender stalk a foot and a half high, dividing into three or four spreading branches, garnished with oblong oval leaves sitting close. The upper part of the branches have two leafy borders or wings, running from one leaf to the other, but the lower part of the branches have none; the foot-stalks of the flowers arise from the side of the stalk, those from the lower part of the branches are above a foot long, the upper are about six inches, they are very slender, and sustain one or two pale yellow flowers at their tops, which are not more than half so large as the former sort, and are succeeded by very short turgid pods, in which are inclosed three or four smooth kidney-shaped seeds. This sort requires the same culture as the two former, and flowers at the same season.

The fourth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houstoun; this rises with a shrubby taper stalk near four feet high, sending out many side branches which are very slender, ligneous, and covered with a light brown bark, garnished with very narrow spear-shaped leaves, which are hairy, sitting close to the branches; the younger shoots have a leafy border or wing on two sides, but the old branches have none; the flowers are produced near the end of the branches, three or four growing alternate on a loose spike; they are of a dirty yellow, and small; the pods which succeed them are about an inch long, very turgid, and of a dark blue when ripe. This sort is propagated by seed, which should be sown on a hot-bed, and the plants treated

treated in the same manner as those before; but in autumn they should be placed in the stove, where they will live through the winter, and flower early the following summer, so will perfect their seeds very well.

The seeds of the fifth sort were brought me from the coast of Malabar, which succeeded in the Chelsea garden. This rises with an angular stalk near four feet high, dividing upward into three or four branches, garnished with narrow spear-shaped leaves, placed alternately on very short foot-stalks; they are pretty closely covered with soft silvery hairs. The flowers are produced at the end of the branches, in loose spikes; they are large, and of a deep yellow colour, and the style stands out beyond the standard. The flowers are succeeded by large turgid pods, containing one row of large kidney-shaped seeds.

This plant is annual in England, but by the lower part of the stalk growing woody, it appears to be of longer duration in the country where it naturally grows; though it will not live through the winter here, for if the plants are placed in a stove, the heat is too great for them, and in a green-house they are very subject to mouldiness in damp weather. I have sown the seeds of this in the full ground, where the plants have grown upward of three feet high, and have flowered very well, but no pods were formed on these; and when they have been treated tenderly, the plants have grown much larger, and produced a greater number of flowers, but these have produced no seeds. The only way which I could ever obtain any seeds, was by raising the plants in pots upon hot-beds; and the beginning of July, turning them out of the pots into the full ground on a very warm border under a wall, in which situation they flowered very well, and some few pods of seeds were ripened. The sixth sort was sent me by the late Dr. Dale from South Carolina, who had the seeds sent him from the country, at a great distance from the English settlements. By the description sent me with the seeds, it grows with a shrubby stalk four or five feet high; but the plants which were raised here, perished at the approach of winter, so that they only flowered, without producing any pods. The stalks of this are round, and covered with a light brown bark, garnished with smooth, oval, heart-shaped leaves, which are about four inches long, and near three broad; surrounding the stalk in such a manner, as if it were run through the middle of the leaves. The flowers grow singly, sitting close to the bosom of each leaf, toward the upper part of the branches; they are of a pale yellow colour, and appear here in August; but as the plants did not produce any pods, so I can give no account of them. This is one of the most singular plants of the genus I have yet seen.

The seventh sort rises with an herbaceous stalk near three feet high, dividing upward into several branches, garnished with oblong leaves, which are narrow at their base, but gradually widen to the top, where they are rounded and indented in the middle in the shape of a heart; they are of a pale green, and smooth. The flowers are produced in spikes at the end of the branches, they are pretty large, and of a yellow colour. These appear in July, and the seeds ripen in autumn, provided the plants are brought forward in the spring, and afterward treated in the same manner as hath been directed for the first sort. This grows naturally in the island of Ceylon, and is an annual plant, perishing soon after it perfects seeds. I received the seeds of this plant from the late Dr. Boerhaave, professor at Leyden.

The eighth sort grows naturally at the Cape of Good Hope, from whence I received the seeds. This rises with a shrubby stalk about five feet high, dividing into several branches, garnished with roundish leaves, sitting close to the branches; they are of a hoary green, and soft to the touch, the branches are taper and smooth; the flowers are produced at the end of the branches in loose spikes; they are about the size of those of the first sort, and of a fine blue colour.

This plant flowers in June and July, and in warm seasons will ripen its seeds in autumn. It is propagated by seeds, which must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, should be each transplanted into a small halfpenny pot, and plunged into a hot-bed of tanners bark, and after must be treated in the same manner as hath been directed for the fourth sort, placing the plants in a moderate stove in winter, otherwise they cannot be preserved in England; the second year the plants will flower, and with proper care their seeds will ripen.

The ninth sort was sent me from Campeachy, where the plant grows naturally; this rises with a taper upright stalk near three feet high, dividing upward into several hairy branches, which grow erect, garnished with oval spear-shaped leaves, of a pale green colour; the flowers are produced singly from the side of the branches, which are of a bright yellow, and are succeeded by short turgid pods, having one row of kidney-shaped seeds. It flowers in July and August, and with the same treatment as hath been directed for the first sort, will perfect seeds in autumn. This is an annual plant, which perishes soon after the seeds are ripe.

The tenth sort grows naturally in India; this rises with a shrubby stalk four or five feet high, dividing into many branches, garnished with ternate oval leaves ending in points; the flowers are large, yellow, growing in large bunches from the side of the branches; they appear in July, August, and September, but I have not seen any pods succeed them here. However, when the plants are in flower, they make a fine appearance.

It is easily propagated by cuttings, during the summer months, if the cuttings are planted in pots, and plunged into a moderate hot-bed, being careful to shade them till they have taken root, and frequently refresh them with water: during the months of July, August, and September, the plants may be exposed to the open air in a sheltered situation, where they will produce many flowers; but in the autumn they should be placed in a temperate stove, to preserve them in winter.

The eleventh sort grows naturally in Virginia and Carolina, from both those countries I have received the seeds; there are two varieties of this species, one with a white, and the other a blue flower; but the seeds of one will produce both varieties, as I have more than once experienced. The root is perennial, sending up every spring a number of leaves, in proportion to the size of the root; the foot-stalks of the leaves are smooth, rising two feet high, dividing upward into three or five branches, garnished with ternate smooth leaves, whose lobes are oval, spear-shaped, and entire; the foot-stalks of the flowers arise immediately from the root, and advance rather higher than the leaves, being terminated by a thyrse of large butterfly-shaped flowers, near a foot in length; in one variety they are white, and in the other deep blue: these are succeeded by large swelling pods, of a black colour when ripe, having one row of kidney-shaped seeds. It flowers in June, and the seeds ripen in the autumn.

It is propagated by seeds, which should be sown on a moderate hot-bed in the spring; when the plants come up they should have free air admitted to them daily, to prevent their drawing up weak, and as soon as they are fit to remove, they should be each planted in a separate small pot, plunging them into a moderate hot-bed again, observing to shade them till they have taken fresh root; then they should be gradually inured to the open air; but in the autumn they should be placed in a common frame, or covered with mats in winter to shelter them; but the following spring they should be turned out of the pots, and planted in the full ground, where, if the soil is dry, and the situation sheltered, they will live many years, producing flowers and seeds annually.

As most of these plants are annual, so they require to be brought forward in the spring, otherwise the summers are too short for them to perfect seeds; so that unless they are carefully managed, they will not flower well here; for in general, the summers in this country are not very favourable for these tender plants. Therefore in order to have these tender annual plants in perfection, there should be a low glass-case erected about five or six feet high, which should be made with glasses to open or slide down on every side, as should also the top on both sides, having sliding glasses, that the plants may have sun and air on every side; in this there should be a pit for tanners bark to make a hot-bed, the whole extent, (a particular description of which will be exhibited under the article STOVE) in this hot-bed may be placed all the very curious tender annual plants, where the sun will constantly shine on them, so long as he makes his appearance above the horizon; and here they may have plenty of free air admitted at all times, when the weather is warm, so may be brought to equal perfection, as in the warm countries where they naturally grow; for the warmth of the tan to the roots, and the heat of the sun through the glasses, will in summer, be equal to the heat of most countries.

These plants naturally grow on sandy light soils, so they should always be planted in such; and the pots in which they are planted, must not be too large, for in such they will not thrive, so that after they have filled the small pots with their roots in which they were first planted, they should be shaken out of those, and put into penny pots, which will be large enough for most of the annual kinds; but those which are of longer duration, will require pots a little larger the following spring. The waterings of these plants should be performed with caution, for too great moisture will rot the fibres of their roots; so that in summer, if they are gently watered three or four times a week in hot weather, it will be sufficient.

CROTON. Lin. Gen. Plant. 960. Ricinoides. Tourn. Inst. 655. tab. 423. Bastard Ricinus.

The CHARACTERS are,

It hath male and female flowers in the same plant; the flowers have a five-leaved empalement, they have five petals, those of the male being no larger than the leaves of the empalement; the male have five nectarious glands, which are small, and fixed to the receptacle; these have ten or fifteen stamina, which are joined at their base, and terminated by twin summits. The female flowers have a roundish germen, supporting three reflexed spreading styles, crowned by bifid reflexed stigmas; the germen afterward becomes a roundish three-cornered capsule, with three cells, each containing a single seed.

This genus of plants is ranged in the ninth section of Linnæus's twenty-first class, intitled Monœcia Monodelphia. The plants of this class and section have male and female flowers in the same plant, and the male parts are joined in one body.

The SPECIES are,

1. **CROTON** (*Tinctorium*) foliis rhombeis repandis, capsulis pendulis caule herbaceo. Hort. Upsal. 290. *Croton with rhomboid reflexed leaves, pendulous capsules, and an herbaceous stalk. Ricinoides ex qua paratur. Tournsol. Gallorum. Tourn. Inst. 655. Bastard Ricinus, from which the Tournsole of the French is made.*
2. **CROTON** (*Argenteum*) foliis cordato-ovatis subtus tomentosis integris subserratis. Hort. Cliff. 444. *Croton with oval heart-shaped leaves, which are entire and woolly. Ricinoides herbacea, folio subrotundo serrato fructu parvo conglomerato. Houst. MSS.*
3. **CROTON** (*Palustre*) foliis ovato-lanceolatis plicatis serratis scabris. Hort. Cliff. 445. *Croton with oval spear-shaped leaves, which are plaited, sawed, and rough. Ricinoides palustre, foliis oblongis serratis fructu hispido. Martyn. Cent. 38.*
4. **CROTON** (*Lobatum*) foliis incrimis serratis, inferioribus quinquelobis, superioribus trilobis. Hort. Cliff. 445. *Croton with leaves smoothly sawed, the lower ones having five lobes, and the upper three. Ricinoides herbacea,*

foliis trifidis vel quinquefidis & serratis. Houst. MSS.

5. **CROTON** (*Humile*) tetraphyllum, foliis lanceolatis, acuminatis subtus cæsiis, caule herbaceo ramoso. *Four-leaved Croton with spear-shaped pointed leaves, gray on their under side, and a branching herbaceous stalk. Ricinoides humilis foliis oblongis acuminatis, subtus cæsiis. Houst. MSS.*
6. **CROTON** (*Fruticosum*) foliis lanceolatis glabris, caule fruticoso, floribus alaribus & terminalibus. *Croton with smooth spear-shaped leaves, a shrubby stalk, and flowers growing from the sides and tops of the branches. Ricinoides frutescens, lauri folio, calyce amplissimo viridi. Houst. MSS.*
7. **CROTON** (*Populi folia*) foliis cordatis, acuminatis, subtus tomentosis, floribus alaribus sessilibus, caule fruticoso. *Croton with heart-shaped pointed leaves, woolly on their under side, and flowers growing close to the sides of the stalks, which are shrubby. Ricinoides foliis populi hirsutis. Plum. Cat. 20.*
8. **CROTON** (*Cascarilla*) foliis lanceolatis acutis integerrimis petiolatis subtus tomentosis, caule arboreo. Amœn. Acad. 5. p. 411. *Croton with spear-shaped, entire, acute-pointed leaves, woolly on their under side, and a tree-like stalk. Ricinoides frutescens odorata, foliis angustis subtus albicantibus. Houst. MSS. Cascarilla.*
9. **CROTON** (*Althæaefolia*) foliis oblongo-cordatis tomentosis, caule fruticoso ramoso, floribus spicatis terminalibus. *Croton with oblong, heart-shaped, woolly leaves, a shrubby branching stalk, and flowers growing in spikes at the ends of the branches. Ricinoides Americana frutescens, Althææ folio. Plum. Cat. 20.*
10. **CROTON** (*Salviæ folia*) foliis cordatis acutis, subtus tomentosis, caule fruticoso, floribus spicatis terminalibus & alaribus. *Croton with pointed heart-shaped leaves, woolly on their under side, a shrubby stalk, and flowers growing in spikes on the tops and sides of the branches. Ricinus salviæ folio utrinque molli. Pet. Hort. Sic.*

The first sort grows naturally in the south of France, from whence I have frequently received the seeds; this is an annual plant, which rises with an herbaceous branching stalk about nine inches high, garnished with irregular, or rhomboidal figured leaves, which are near two inches long, and one inch and a quarter broad in their widest part; these stand upon slender foot-stalks, near four inches long. The flowers are produced in short spikes from the side of the stalks, at the end of the branches; the upper part of the spike is composed of male flowers, having many stamina, which coalesce at the bottom; the lower part hath female flowers, which have each a roundish three-cornered germen; these afterward become a roundish capsule with three lobes, having three cells, each including one roundish seed. This flowers in July, but unless the plants are brought forward in a hot-bed, they do not ripen seeds in this country.

The seeds of this plant should be sown in the autumn, soon after they are ripe, in a small pot filled with light earth, and plunged into an old tan-bed in a frame, where they may be screened from cold in the winter; and in the spring following the pot should be removed to a fresh hot-bed, which will bring up the plants in a month's time; when these are grown large enough to remove, they should be each planted in a small pot, and plunged into a fresh hot-bed, being careful to shade the glasses daily, until the plants have taken new root; then they should have air daily admitted according to the warmth of the season, and but little water given to them: with this management I have had the plants flower and produce good seeds here, but never could obtain any with other treatment.

This is the plant from which the Tournsole is made, which is used for colouring wines and jellies; it is made of the juice which is lodged between the empalement and the seeds, which, if rubbed on cloths, at first appears of a lively green, but soon changes to a bluish purple colour; if these cloths are put into water, and afterward wrung, they will dye the water to a claret colour; the rags thus dyed, are brought

to England, and sold in the druggists shops by the name of Tournsole.

The second sort grows naturally at La Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houstoun; this is an annual plant, which rises about a foot high; it hath an angular stalk; the branches are naked from their divisions to the top, where they are garnished with a few oval spear-shaped leaves, which are sawed on their edges; they are an inch and a half long, and three quarters of an inch broad, standing on foot-stalks one inch long. The flowers are produced in close short spikes at the end of the branches, those on the upper part being male, and the lower female; they are white, and the male soon falls away, but the female are succeeded by roundish capsules, having three lobes; these grow in close clusters, they have three cells, each containing one roundish seed. It flowers in July, and the seeds ripen in autumn.

The third sort was discovered by the late Dr. Houstoun at La Vera Cruz, from whence he sent me the seeds; this is also an annual plant, which grows naturally in low marshy grounds, where it hath a very different appearance from what it puts on when sown upon dry land; those of the watery places have broad flat stalks, and leaves three inches long, which are scarce a quarter of an inch broad; these are rough, and but little indented on their edges; but those plants upon dry ground have oval leaves three inches long, and upwards of two inches broad, which are sawed on their edges. The flowers are produced at the wings of the leaves, in short loose spikes, having four or five herbaceous male flowers at the top of each, and three or four female flowers at the bottom, which are succeeded by roundish capsules with three lobes, covered with a prickly husk; these have three cells, each inclosing a single seed. It flowers and seeds about the same time as the former.

The fourth sort was discovered by the same gentleman, at the same place as the former; this is an annual plant, which rises with a taper herbaceous stalk a foot and a half high, dividing into several branches, garnished with smooth leaves, standing upon very long foot-stalks, and are for the most part placed opposite, as are also the branches; the lower leaves are divided deeply into five oblong segments or lobes, and the upper into three, which are slightly sawed on their edges, ending in acute points. The flowers are produced in loose spikes at the end of the branches, those on the upper part being male, and the lower female, they are of an herbaceous colour; the female flowers are succeeded by oblong capsules, having three lobes, which open in three parts, having three cells, each containing one oblong seed. This flowers and seeds at the same time as the former sorts.

The fifth sort was found growing naturally at the Havannah, by the late Dr. Houstoun, who sent me the seeds; this is an annual plant, which rarely grows more than six inches high, dividing into two or three branches; the lower part of these are garnished at each joint with four leaves placed in form of a cross, two of which are three inches long, and one inch broad near their base, ending in acute points; these stand opposite, and the other two leaves between these are about two inches long, and a quarter of an inch broad; they are of a light green on their upper side, and of a gray or Ash-colour on their under. The flowers are produced in long loose spikes at the top of the stalks, two or three of these spikes arising from the same joint; the upper part of these spikes have male, and the lower female flowers, of an herbaceous colour; the female flowers are succeeded by round capsules with three cells, each containing one roundish seed. This flowers and seeds about the same time with the former sorts.

The sixth sort was discovered by the late Dr. Houstoun in the island of Jamaica, where it grows naturally. It rises with a shrubby stalk to the height of seven or eight feet, which is covered with an Ash-

coloured bark, and divides into many slender branches upward; some of these branches are terminated by five or six smaller, which arise from the same joint; these are naked below, but toward their upper part they are garnished with smooth spear-shaped leaves, about two inches and a half long, and three quarters of an inch broad, standing on pretty long foot-stalks without order; the flowers are produced in short spikes at the end of the branches, in the same manner as the former; they are of an herbaceous colour, and inclosed in large green empalements.

The seventh sort was sent me from Jamaica, by Mr. Robert Millar; this rises with a shrubby stalk seven or eight feet high, sending out many irregular branches, covered with an Ash-coloured bark, and garnished with heart-shaped leaves, near four inches long, and two inches broad in their widest part, ending in acute points; they are of a light green on their upper side, but woolly on their under, standing on slender foot-stalks without any order, sometimes single, and at others, two or three arise from the same joint. The flowers are produced in short spikes from the side of the branches; they are of a whitish green colour, and the female flowers are succeeded by capsules, having three cells, each including a single seed.

The eighth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houstoun; this rises with a shrubby stalk about six or seven feet high, sending out many side branches, which are covered with a smooth bark, of a yellowish white colour, garnished very closely with narrow stiff leaves near three inches long, and about one eighth of an inch broad, of a light green on their upper side, but their under side is the same colour as the bark; the midrib is furrowed on their upper side, and very prominent on the lower; the upper part of the branches divide into four or five smaller, which arise from the same joint, and are nearly equal in their length, and between these arise a long loose spike of whitish green flowers. The whole plant hath an aromatic odour when rubbed. The seeds grow in roundish capsules having three cells, each including a single seed.

The ninth sort grows naturally in Jamaica, from whence it was sent me by the late Dr. Houstoun; this rises with a shrubby stalk six or seven feet high, dividing upward into several branches, which are covered with a yellowish down, garnished with long heart-shaped leaves, ending in acute points; these are two inches and a half long, and one broad in their widest part, standing on long foot-stalks, covered on both sides with a woolly down of the same colour as the branches. The flowers are produced on long close spikes at the end of the branches; the male flowers, which are situated on the upper part of the spikes, have white flowers of one leaf, divided into five parts almost to the bottom, and have five taper stamina, situated in the bottom. The female flowers on the lower part of the spikes, have large woolly empalements, and are succeeded by round capsules with three cells, each including a single seed.

The tenth sort rises with a shrubby stalk near four feet high, dividing into many smaller branches, which have a silvery bark, and are garnished with small heart-shaped leaves, about three quarters of an inch long, and half as broad at their base, ending in acute points; these are woolly on both sides, but their under side is silvery, their upper side of a yellowish green. The flowers are produced in short spikes at the end of the branches, which are small, white, and have woolly empalements. The female flowers on the lower part of the spikes are succeeded by roundish capsules with three cells, each containing one seed.

All these plants except the first, are natives of warm countries, so will not thrive in England, unless they are tenderly treated. They are all propagated by seeds; those which are annual perfect their seeds in England;

C R U

England; but the shrubby sorts very rarely arrive to that perfection, so their seeds must be procured from the countries where they naturally grow. The seeds must be sown on a hot-bed early in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot, and plunged into a moderate hot-bed of tanners bark, where they should be shaded from the sun till they have taken fresh root; then they must have air admitted to them daily, in proportion to the warmth of the season; they must also be frequently refreshed with water, particularly the second, third, and fourth sorts, which will often require water, but the others should have it more sparingly. After the plants are grown too tall to remain in the frames, they should be removed, either into the stove, or a glass-case, where there is a hot-bed of tanners bark, into which the pots should be plunged, and there the annual sorts will flower and perfect their seeds; but the shrubby kinds must be removed into the bark-stove in the autumn, and during the winter season they should have but little water; and the stove should be kept in a good temperature of heat, otherwise they will not live through the winter in England.

As these plants retain their leaves all the year, so they make a pretty variety in winter, when they are intermixed with other plants, whose leaves are of different forms and colours from these.

CROWN IMPERIAL. See **PETILIVM.**

CRUCIANELLA. Lin. Gen. Plant. 118. Rubeola. Tourn. Inst. R. H. 130. tab. 50. Petty Madder.

The CHARACTERS are,

The flower hath a two-leaved empalement, which is rigid and compressed. It hath one petal, with a slender cylindrical tube which is longer than the empalement, and cut into four parts at the brim. It hath four stamina situated in the mouth of the tube, terminated by single summits. It hath a compressed germen, situated at the bottom of the tube, supporting a slender bifid style, crowned by two obtuse stigmas. The germen afterward become two twin capsules, each containing one oblong seed.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

The SPECIES are,

1. **CRUCIANELLA** (*Angustifolia*) erecta, foliis senis linearibus. Hort. Upsal. 27. Upright Crucianella with six narrow leaves. Rubeola angustiore folio. Tourn. Inst. 130. Petty Madder.
2. **CRUCIANELLA** (*Latifolia*) procumbens, foliis quaternis lanceolatis, floribus spicatis. Hort. Upsal. 27. Trailing Crucianella with four spear-shaped leaves and spiked flowers. Rubeola latiore folio. Tourn. Inst. 130.
3. **CRUCIANELLA** (*Maritima*) procumbens suffruticosa foliis quaternis, floribus oppositis quinquefidis. Lin. Sp. Plant. 158. Crucianella with trailing shrubby stalks, four leaves at each joint, and flowers growing in whorls. Rubeola maritima. C. B. P.
4. **CRUCIANELLA** (*Hispida*) caule hispido, foliis lanceolatis hirsutis oppositis, floribus umbellatis terminalibus. Crucianella with a stinging stalk, spear-shaped hairy leaves placed opposite, and flowers growing in umbels at the ends of the branches. Rubeola Americana hirsuta, parietariæ foliis, floribus umbellatis purpureis. Houst. MSS.
5. **CRUCIANELLA** (*Americana*) foliis linearilanceolatis hirsutis oppositis, caule erecto villoso, floribus solitariis alaribus. Crucianella with narrow, spear-shaped, hairy leaves placed opposite, an erect hairy stalk, and single flowers proceeding from the sides of the branches.

The first sort grows naturally in the south of France and Italy; this is an annual plant, which rises with several upright stalks a foot high, having six or seven very narrow linear leaves placed in whorls, at each joint. The flowers grow in close spikes at the top and from the side of the branches; these are small, white, and not longer than the empalement, so make no great appearance. It flowers in June and July, and the seeds ripen in autumn.

C U C

The second sort grows in the islands of the Archipelago, and also about Montpellier; this is also an annual plant, sending out several branching stalks from the root, which lie prostrate, and are garnished with four spear-shaped leaves at each joint. The flowers are produced in long spikes at the extremity of the branches; these are very small, so make no great appearance. It flowers about the same time as the former.

The third sort is like the second in the appearance of leaves and stalks, but the flowers grow on the side of the stalks, almost in whorls, and make little appearance. This grows naturally on the borders of the sea, in the south of France and Italy.

These three sorts are preserved in some gardens for the sake of variety; if the seeds are sown on a bed of light earth early in the spring, where they are designed to remain, they will require no other culture, but to thin them where they are too close, and keep them clean from weeds; or if the seeds are permitted to scatter, the plants will come up in the spring, and require no other treatment; but the third sort will not ripen its seeds here, when the autumn is not favourable.

The fourth sort hath four-cornered, rough, prickly stalks, which bend downward, and are garnished with spear-shaped leaves, which are hairy and stand opposite; the flowers are produced in small clusters at the end of the branches, which are blue, and cut into four parts at the top; after these decay, they are succeeded by twin capsules joined, in each of these is one oblong seed.

The fifth sort rises with a shrubby branching stalk near three feet high, which is garnished with narrow spear-shaped leaves, covered with stinging hairs. The flowers are produced from the wings of the leaves, on each side the stalk singly; these are of a pale blue colour, and are succeeded by twin fruit like the former.

Both these sorts grow naturally at La Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houstoun; and the plants grew in the Chelsea garden very well during the summer season; but perished in the autumn before their seeds were ripe.

CRUCIATA. See **VALANTIA.**

CRUPINA BELGARUM. See **SERRATULA.**

CUCUBALUS. Lin. Gen. Plant. 502. Tourn. Inst. R. H. 339. tab. 176. Berry-bearing Chickweed.

The CHARACTERS are,

The flower hath an oblong permanent empalement of one leaf, cut into five segments. It hath five petals, with tails as long as the empalement, but spread open at the top. It hath ten stamina, five of which are alternately inserted in the tail of the petals; these are terminated by oblong summits. In the center is situated the oblong germen, supporting three styles which are longer than the stamina, crowned by oblong hairy stigmas. The empalement afterward becomes a pointed close capsule with three cells, opening at the top in five parts, and filled with many roundish seeds.

This genus of plants is ranged in the third section of Linnæus's tenth class, intitled Decandria Trigynia, the flowers having ten stamina and three styles.

The SPECIES are,

1. **CUCUBALUS** (*Bacciferus*) calycibus campanulatis, petalis distantibus, pericarpis coloratis, ramis divaricatis. Lin. Sp. Plant. 414. Cucubalus with a bell-shaped empalement, petals standing asunder, a coloured cover to the fruit, and divaricated branches. Cucubalus Plinii. Lugd. 1429.
2. **CUCUBALUS** (*Latifolius*) caulibus erectis glabris, calycibus subglobosis, staminibus corollâ longioribus. Cucubalus with smooth erect stalks, globular empalements, and stamina longer than the petals. Lychnis sylvestris quæ behen album vulgò. C. B. P. 205. Commonly called Spatling Poppy.
3. **CUCUBALUS** (*Angustifolius*) calycibus subglobosis, caule ramoso patulo, foliis linearibus acutis. Cucubalus with globular empalements, a branching spreading stalk, and

and narrow-pointed leaves. *Lychnis sylvestris* quæ behen album vulgò, foliis angustioribus & acutioribus. C. B. P. 250. *Spatling Poppy*, with narrower pointed leaves.

4. **CUCUBALUS** (*Behen*) calycibus subglobosis glabris reticulato-venosis, capsulis trilocularibus corollis subnudis. Flor. Suec. 360. *Cucubalus* with smooth globular empalements which have netted veins, capsules having three cells, and naked petals. *Lychnis Suecica behen album* folio, habitu, calyce amplissimo: gumsepungar five scrotum arietis dicta. Boerh. Ind. alt. 212. Called *Gumsepungar* in Sweden.
 5. **CUCUBALUS** (*Tabarius*) foliis obovatis carnosiss. Prod. Leyd. 448. *Cucubalus* with oval fleshy leaves. *Lychnis maritima saxatilis*, folio anacampserotis. Tourn. Cor. 24.
 6. **CUCUBALUS** (*Dubrensis*) floribus lateralibus decumbentibus, caule indiviso, foliis basi reflexis. Lin. Sp. Plant. 414. *Cucubalus* with declining flowers on the sides of the stalk, which is undivided, and leaves reflexed at their base. *Lychnis major noctiflora Dubrensis* perennis. Raii Hist. 995. *Greater perennial night-flowering Lychnis of Dover*.
 7. **CUCUBALUS** (*Stellatus*) foliis quaternis. Hort. Upsal. 110. *Four-leaved Cucubalus*. *Lychnis carophyllæus Virginianus*, gentianæ foliis glabris quatuor ex singulis geniculis caulem amplexantibus, flore amplo limbrato. Raii Hist. 1895.
 8. **CUCUBALUS** (*Noctiflora*) calycibus striatis acutis petalis bipartitis, caule paniculato, foliis linearibus. *Cucubalus* with striated acute empalements, petals divided in two parts, a paniculated stalk, and narrow leaves. *Lychnis noctiflora angustifolia odorata*. Tourn. Inst. R. H. 335. *Narrow-leaved, sweet-scented, night-flowering Lychnis*.
 9. **CUCUBALUS** (*Otites*) floribus dioicis, petalis linearibus indivisis. Hort. Cliff. 272. *Cucubalus* with male and female flowers on different plants, and linear undivided petals. *Lychnis viscosa*, flore muscoso. C. B. P. 206.
 10. **CUCUBALUS** (*Acaulis*) acaulis. Flor. Lapp. 184. *Cucubalus* without stalks. *Lychnis Alpina pumila*, folio gramineo, five muscus Alpinus *Lychnidis* flore. C. B. P. 206.
 11. **CUCUBALUS** (*Catholicus*) petalis bipartitis, floribus paniculatis, staminibus longis, foliis lanceolato ovatis. Hort. Upsal. 111. *Cucubalus* with bifid petals, flowers growing in panicles, long stamina, and spear-shaped acute leaves. *Lychnis altissima*, ocymastri facie, flore muscoso. Triumfet.
 12. **CUCUBALUS** (*Paniculatus*) foliis radicalibus ovatis acutis, caulinis lanceolatis oppositis, floribus paniculatis erectis. *Cucubalus* with lower leaves oval and pointed, those on the stalks spear-shaped, opposite, and flowers growing in panicles which are erect.
 13. **CUCUBALUS** (*Italicus*) petalis bipartitis, caule paniculato, foliis radicalibus ovato-lanceolatis caulinis linearibus. *Cucubalus* with petals divided in two parts, a paniculated stalk, whose lower leaves are oval and spear-shaped, and those on the stalks very narrow.
- The first sort grows naturally in France, Germany, and Italy, in shady places, and is seldom kept in gardens, unless for the sake of variety; it sends out many climbing stalks, which grow four or five feet high where they meet with support, otherwise they trail on the ground; these stalks send out side branches opposite, at each joint; the leaves are like those of Chickweed, and are placed opposite. The flowers come out single at the end of the branches, which have large inflated empalements; they consist of five petals, which are white, cut at the brim into several narrow segments, and are placed at a distance from each other; they are succeeded by oval berries, which, when ripe, are black and full of juice, inclosing several flat shining seeds. It flowers in June, and the seeds ripen in autumn. This hath a perennial creeping root, whereby it is apt to multiply too fast in gardens. It delights in shade, and will thrive in almost any soil.
- The second sort grows naturally in most parts of England, where it is generally called *Spatling Poppy*. This stands in the catalogue of medicinal plants,

under the title of *Behen album*; the roots of it are sometimes used, and are accounted cordial, cephalic, and alexipharmic. It hath a perennial root, which strikes deep into the ground, so that they are not easily destroyed by the plough, therefore it is frequently seen growing in bunches among corn. It is a rambling weed, so is seldom cultivated.

The third sort grows naturally on the Alps; this differs from the former, in having much longer and narrower leaves, and the stalks being more divided and spreading, nor do the roots creep under ground like that. These differences are constant, for I have sown it above thirty years, and never found it vary.

The fourth sort grows naturally in Sweden, and some other northern countries, where it passes for the common sort; but although it is there so, yet is very different from the second here mentioned, which is the sort that grows common in most other parts of Europe. The stalks of this are much larger, the leaves longer and more pointed; the empalement of the flower is curiously veined like net-work, of a purplish colour, whereas that of our common sort is plain. These differences are lasting, when the plants are cultivated in a garden.

The fifth sort was discovered by Tournefort in the Levant, who sent the seeds to the royal garden at Paris. This puts out many oval, thick, succulent leaves near the ground, out of the middle of which, arises an upright stalk about fifteen inches high, the lower part of which is garnished with leaves of the same form and consistence as those at bottom, but are smaller; these are placed opposite; the upper part of the stalk divides into two smaller, on which stand a few small herbaceous flowers at each joint. It flowers in June, and sometimes ripens seeds in autumn. The plant is biennial, generally perishing when it has produced seeds; but unless it is sown upon a very dry rubbish, and in a warm situation, the plants will not live through the winter in England; for when they are in good ground, they grow large, and are so replete with moisture, as to be affected by the first frost in the autumn; but where they have grown upon an old wall, I have known them escape, when all those were killed which grew in the ground.

The sixth sort grows naturally upon the cliffs near Dover. This hath a perennial root, from which arises a single stalk about a foot and a half high, garnished with long narrow leaves placed opposite; the flowers are produced from the side of the stalks, each foot-stalk sustaining three flowers; the foot-stalks come out by pairs opposite, the empalement of the flower is long and striped, the flowers are of a pale red. These appear in June, and the seeds ripen in autumn.

The seventh sort grows naturally in Virginia, and several other parts of North America. This hath a perennial root, from which arise two or three slender upright stalks about a foot high, their lower part being garnished with four leaves at each joint, placed in form of a cross; these are smooth, of a deep green, about an inch and a half long, and half an inch broad near their base, terminating in acute points; the joints of the upper part of the stalk are garnished with white fringed flowers, standing single upon pretty long foot-stalks, which come out by pairs opposite. The flowers appear in June, and in warm seasons the seeds will ripen in England.

The eighth sort grows naturally in Spain and Italy. This is a perennial plant, which rises with an upright branching stalk a foot and a half high, garnished with very narrow leaves placed opposite; the upper part of the stalk is very branching; some of these branches are long, and others short; the flowers stand upon long naked foot-stalks, each supporting three or four flowers, which have long tubes, with striped empalements; the petals are large, and deeply divided at the top; they are of a pale bluish colour. These flowers are closed all day, but when the sun leaves them, they expand, and then they have a very agreeable scent. This sort may be propagated by seeds,

seeds, which should be sown in the spring upon a bed of light earth; and when the plants are fit to remove, they should be planted in a nursery-bed, at about four inches distance, where they may remain till autumn, when they may be planted in the borders of the flower-garden, where they are designed to remain. The following summer these will produce their flowers, and ripen their seeds in the autumn; but the roots will continue several years, provided they are not planted in rich ground, where they are very subject to rot in winter.

The ninth sort grows naturally in Austria, Silesia, and Italy, as also in some parts of England. This is male and female in different plants; it hath a thick, fleshy, biennial root, which strikes deep in the ground, sending out many oblong leaves, which are broad at their extremity, but contract narrower to their base; from between these arise the stalks, which in the male plants often grow four or five feet high, but those of the female are seldom above three feet high; the stalks are garnished with narrow leaves, placed opposite at each joint, where there exsudes a viscous clammy juice, which sticks to the fingers when handled, and the small insects which settle upon those parts of the stalks, are thereby fastened so as not to get loose again. The flowers of the male plants are produced in loose spikes from the lower joints of the stalk, but on the upper part, they stand on single foot-stalks in clusters quite round the stalks; these are small, of a greenish colour, and have each ten stamina. The female plants have three or four flowers growing upon each foot-stalk, which arise from the side of the stalk. These are succeeded by oval seed-vessels, containing many small seeds; they flower in June, and the seeds ripen in autumn. This is propagated by seeds, which should be sown where the plants are designed to remain; for as they send out long tap-roots, they do not bear transplanting, unless it is performed while the plants are young. The plants are very hardy, so will thrive in almost any soil or situation, but agree best with a dry soil. It is necessary to have some male plants among the female, to have perfect seeds.

The tenth sort grows naturally on the Alps, and also upon the hills in the north of England and Wales. This is a very low plant, with small leaves, which spread on the ground, and have the appearance of moss. The flowers are small, erect, and rarely rise more than half an inch high; they are of a dirty white colour, and appear in May. This is a perennial plant, which will not thrive but in a moist soil and a shady situation.

The eleventh sort grows naturally in Italy and Sicily. This is a perennial plant, with large thick roots, sending out many long spear-shaped leaves near the ground; between these arise round viscous stalks, which grow three feet high, garnished at each joint by two long narrow leaves, ending in acute points. The stalks branch out into many divisions, on the upper parts of which the foot-stalks of the flowers arise from each joint by pairs opposite; each of these sustain three or four flowers of an herbaceous colour, whose petals are divided into two parts; the flowers appear in June, and the seeds ripen in the autumn. This is propagated by seeds in the same manner as the ninth.

The twelfth sort grows naturally in Spain and Italy, from whence I received the seeds. This is a biennial plant, which decays soon after it hath perfected seeds: this hath many oval pointed leaves near the root, standing upon long foot-stalks; between these arise an upright stalk, sending out two side branches at each joint, placed opposite; under each of these is situated one spear-shaped leaf, ending in an acute point; these side branches, and also the upright stalks, are terminated by whitish flowers, formed into a panicle, and standing erect; these appear in June, and are succeeded by seeds which ripen in autumn. This is propagated by seeds, which may be sown on an open border where the plants are designed to re-

main, and require no other culture but to keep them clear from weeds.

The thirteenth sort grows naturally in Italy, from whence I received the seeds; this is a perennial plant, which hath many oval spear-shaped leaves near the root; the stalks rise about two feet high; they are viscous, and from each joint comes out two side branches, under which are situated two very narrow leaves; the stalks spread out and form a sort of panicle, and are terminated by clusters of greenish flowers, whose petals are divided into two parts. This flowers in June, and the seeds ripen in autumn. It is propagated in the same manner as the ninth sort, and requires the same treatment.

CUCULATE PLANTS are so called, of cuculla, *Lat.* a hood or cowl, such as monks wear, because their flowers resemble it.

CUCUMIS. *Lin. Gen. Plant.* 969. *Tourn. Inst. R. H.* 104. tab. 28. Cucumber; in French, *Concombre.*

The CHARACTERS are,

It hath male and female flowers placed at distances on the same plant; these have a bell-shaped empalement of one leaf, whose border is terminated by five bristles. The flowers are bell-shaped, have one petal which adheres to the empalement, and is cut into five oval rough segments. The male flowers have three short stamina, which are inserted to the empalement, two of which have bifid tips. These are terminated by very narrow summits or lines, which run upward and downward, and adhere to the outside. The female flowers have no stamina, but have three small pointed filaments without summits. The germen, which is oblong, is situated under the flower, supporting a short cylindrical style, crowned by three thick convex stigmas, which are bipartite. The germen afterward becomes an oblong fleshy fruit with three cells, including many oval, flat, pointed seeds.

This genus of plants is ranged in the tenth section of Linnæus's twenty-first class, intitled Monœcia Syngenesia. The plants of this class have male and female flowers on different parts of the same plant, and those of this section have their stamina joined. To this genus he has joined the Melon, Water Melon, and Bitter Apple; but however these may agree in their characters, so as to be joined together in a system of botany, it will not be proper in a book of gardening to be followed.

The SPECIES are,

1. **CUCUMIS** (*Sativus*) foliorum angulis rectis, pomis oblongis scabris. *Hort. Cliff.* 451. *Cucumber with leaves having right angles, and an oblong rough fruit. Cucumis sativus vulgaris. C. B. P.* 310. *The common Garden Cucumber.*
2. **CUCUMIS** (*Flexuosus*) foliorum angulis rectis, pomis longissimis glabris. *Cucumber with leaves having right angles, and a very long smooth fruit. Cucumis flexuosus. C. B. P.* 310. *The long Turkey Cucumber.*
3. **CUCUMIS** (*Chata*) hirsutis foliorum angulis integris dentatis, pomis fusciformibus hirtis utrinque attenuatis. *Hasselq. It.* 491. *Hairy Cucumber with angular indented leaves, and narrow hairy fruit. Cucumis Ægyptius rotundifolius. C. B. P.* 310.

The first sort is the Cucumber which is generally cultivated for the table, and is so well known as to need no description. The second sort is the long Turkey Cucumber, which is also pretty well known in England. The stalks and leaves of this sort are much larger than those of the common sort. The fruit is generally twice the length, and hath a smooth rind: this is undoubtedly different from the common sort, for I have cultivated it above forty years, and have not found it alter. There are green and white fruit of this sort, which differ but little except in their colour, so I have not distinguished them as distinct species, though I have also found them keep their difference from seeds. The white is less watery than the green, so is generally better esteemed. I have also received seeds from China of another sort, with a much longer fruit than the Turkey, but I have found this will degenerate in time, and become more like the common sort.

In Holland they cultivate a long white prickly Cucumber only, which is very different from the Turkey Cucumber, being near as rough as the common sort; but this is not so hardy as our common sort, so is seldom cultivated in England; but the fruit is not so watery or full of seeds as the common, therefore is preferable to it for the table.

The third sort here enumerated is rarely cultivated, but in botanic gardens for the sake of variety, the fruit being very indifferent, and the plants being tender, require a good heat to bring them to perfection in England; these plants ramble very far, so must have much room, and they are not very fruitful.

The common sort is cultivated in three different seasons, the first of which is on hot-beds under garden-frames, for early fruit; the second is under bell or hand-glasses, for the middle crop; and the third is in the common ground, for a late crop, or to pickle.

I shall begin with giving directions for raising Cucumbers early, which is what most gentlemen gardeners have an emulation to excel each other in; and some have been at the pains and expence to have ripe fruit in every month of the year, which is rather a curiosity than any real advantage; for Cucumbers that are produced before April, cannot be so wholesome as those that are later; for before the sun hath strength enough to warm the beds through the glasses in the day-time, all the heat must proceed from the fermentation of the dung, which must consequently occasion a very considerable steam, as also a great quantity of air will be thereby generated, which, being pent up in the hot-bed, soon becomes rancid; and the steam of the bed being by the cold of the night condensed into large drops of water, these, being absorbed or inspired by the plants, must certainly make the fruit crude and unwholesome, especially when the nights are very long. This, together with the great expence and trouble of procuring them earlier, having in some measure got the better of peoples ambition, so this is less practised than it hath been some years since; but as there are many persons who yet value themselves on their skill in raising early Cucumbers, we may probably be censured, as being deficient in what they call an essential part of gardening, should we omit the method practised for raising these fruit early in the year. Therefore shall proceed to give such directions, as if carefully attended to, will not fail of success.

Those persons who are very desirous to be early with their Cucumbers, generally sow their seeds before Christmas, but the generality of gardeners commonly put their seeds into the hot-bed about Christmas. Where persons have the conveniency of a stove for raising these plants, it is attended with less trouble than a common hot-bed, and is a much surer method, because the plants will have a much greater share of air, which will also be less mixed with damp or rancid vapours; for by the heat of the fires these will be dissipated, and the temperature of the air is kept more equal than can be done with all possible care in a hot-bed, at a season when we enjoy but little sun; therefore where there is this convenience, the seeds should be sown in small pots, filled with light dry earth, and plunged into the tan-bed, in the warmest part of the stove. The pots with earth should be plunged three or four days before the seeds are sown, that the earth may be properly warmed to receive them; the seeds should be at least three or four years old, but if it is more, provided it will grow, it will be the better. If the seeds are good, the plants will begin to appear in about a week or nine days, at which time there must be as many halfpenny pots filled with dry light earth, as there are plants designed for planting (always allowing for loss; so that where twenty-four plants are wanting, there should be thirty raised); these pots should be plunged into the bark-bed, that the earth may be warmed to receive the plants, which should be pricked into these pots as soon as the two first leaves are raised above ground; into each of these pots may be two plants pricked, but

when they have taken root, and are safe, the worst should be drawn out, being careful not to disturb the roots of those which are left. In the management of these plants, there must be great care taken not to give them too much water; and it will be very proper to put the water into the stove some hours before it is used, that the cold may be taken off; but there must be caution used not to make it too warm, for that will destroy the plants; they must also be guarded from the moisture which frequently drops from the glasses of the stove, which is very destructive to these plants while young. As these plants must not be kept too long in the stove lest they become troublesome to the other plants, there should be a proper quantity of new dung prepared for making a hot-bed to receive them; this must be in proportion to the quantity of holes or plants intended: for a middling family six or nine lights of Cucumbers will be sufficient, and for a large one double the quantity; but the beds where they are designed to remain need not be made so soon, but rather a small bed of one light, in which the plants may be trained up, till they have acquired a greater share of strength; and for this bed one good cart load of dung will be sufficient. This should be new, and not too full of straw, nor should it want a proper portion; it should be well mixed together and thrown in a heap, mixing some sea-coal ashes with it; after it hath lain in a heap a few days, and has fermented, it should be carefully turned over and mixed, laying it up again in a heap; and if there is a great share of straw in it, there may be a necessity for turning it over a third time, after having laid a few days: this will rot the straw and mix it thoroughly with the dung, so there will be less danger of its burning afterward when the bed is made, which should be done when the dung is in proper order. The place where the hot-bed is made should be well sheltered by Reed hedges, and the ground should be dry; then there should be a trench made in the ground, of a proper length and breadth, and a foot deep at least; into which the dung should be wheeled and carefully stirred up and mixed, so that no part of it should be left unseparated, for where there is not this care taken, the bed will settle unequally; there should also be great care taken to beat the dung down close in every part of the bed alike. When the bed is made, the frame and glasses should be put upon it to keep out the rain, but there should be no earth laid upon the dung till two or three days after, that the steam of the dung may have time to evaporate. If there should be any danger of the bed burning, it will be proper to lay some short old dung, or some neats dung, over the top of the hot dung about two inches thick, which will keep down the heat, and prevent the earth from being burnt; after this there should be a sufficient number of three farthing pots placed upon the bed, filled with light dry earth, and all the interstices between them filled up with any common earth. In two or three days the earth in these pots will be of a proper temperature of warmth to receive the plants, which should be then turned out of the halfpenny pots, preserving the ball of earth to their roots, and planted into the three farthing pots, filling up the pots with good earth; then a little water should be given them to settle the earth about their roots, being careful not to give them too much wet; and as these will have such large balls of earth to their roots, they will not feel their movement, therefore will not require shading from the sun; but the glasses should be raised up a little on the contrary side from the wind, to let the steam of the bed pass off; and they should also be frequently turned in the day-time, that the wet occasioned by the steam of the dung may be dried, otherwise the moisture will fall on the plants, which will be very injurious to them. If the bed should heat too violently, so as to endanger scalding the roots of the plants, the pots may be raised so as to allow of a little hollow at their bottoms, which will effectually prevent injury thereby; and when the heat declines, the pots may be settled down again.

again. The glasses of the hot-bed should be well covered with mats every night, to keep the bed in a proper temperature of heat, and great care must be taken to admit fresh air every day to the plants; but this should be done with caution, so as to guard against the cold winds which usually blow at that season; so that a mat or canvas should be hung over the opening made by raising of the glasses, to prevent the cold air from rushing in too violently, and the glasses should always be raised on that side which is contrary to the wind. The plants will also require to be frequently watered, but it must be cautiously given them at this season, and the water should not be cold, but either placed in a stove, or put into a warm heap of dung, to take off the chill from it before it is used.

If the weather should prove bad, and the heat of the bed decline, there should be some hot dung laid round the sides of the bed to renew the heat, which must not be suffered to fail; for as the plants have been tenderly brought up, they must not suffer from cold, for that will soon destroy them.

In this bed the plants may remain about three weeks or a month, in which time, if they have been properly managed, they will have obtained sufficient strength to put out for good; therefore a proper quantity of dung should have been mixed and turned ready for making of the beds. The usual quantity allowed for making of the beds at this season, is one good cart load to each light: this should be well mixed and turned over in the manner before directed; then a trench should be dug in the ground the length and width of the intended bed, into which the dung should be wheeled, and properly worked according to the above directions, and some old dung or neats dung spread over the top. The frames and glasses should then be put on the bed, which should be raised every day to let the steam of the dung pass off, and in about three days the bed will be in a proper temperature of heat to receive the plants; at which time the dung should be covered over with dry earth about four inches thick, and in the middle of the bed it should be three or four inches thicker; this should be laid upon the dung at least twenty-four hours before the plants are removed into the bed, that the earth may be properly warmed; then the plants should be carefully shaken out of the pots, preserving all the earth to their roots, and placed on the top of the earth in the middle of the bed. Two, or at most, three of these plants will be sufficient for each light, and these should be placed at about seven or eight inches asunder, not all the roots together, as is too often practised. When the plants are thus situated in the bed, the earth which was laid so much thicker in the middle of the bed, should be drawn up round the ball which remained to the roots of the plants, into which their roots will soon strike; there should always be a magazine of good earth laid under cover to keep it dry, for the earthing of these beds; for if it is taken up wet, it will chill the beds, and also occasion great damps therein, therefore it is quite necessary to have a sufficient quantity of earth prepared long before it is used. When the plants are thus settled, they must have proper air and water, according as they may require, being careful not to admit too much cold air, or give too much water; the glasses should also be well covered with mats every night, to keep up the warmth of the bed, and some fresh earth should be put into the bed at different times, which should be laid at some distance from the roots of the plants till it is warmed, and then should be drawn up round the heap of the earth in which the plants grow, to increase the depth; this should be raised to the full height of the former ball, that the roots of the plants may more easily strike into it: by this method of supplying the earth, the whole surface of the beds will be covered nine or ten inches with earth, which will be of great service to the roots of the plants; for where the earth is very shallow, the leaves of the plants will always hang in the heat of the day, unless they are shaded,

and the plants will require more water to keep them alive, than is proper to give them; therefore it will be found much the better way to allow a proper depth of earth to the beds: but the reason of not laying the quantity of earth on the bed when it is first made, is, that the dung should not be too much chilled by it, or that the earth may not be burned, which might be endangered thereby, were the whole thickness to be laid on at once; besides, by thus gradually applying the earth, it will be fresh, and much better for the roots of the plants, than that which has been long upon the bed, and has been too much moistened by the steam arising from the dung.

If the heat of the bed should decline, there should be some hot dung laid round the side of the bed to renew the heat; for if that should fail at the time when the fruit appears, they will fall off and perish, therefore this must be carefully regarded; and when the plants have put out side branches (which the gardeners call runners) they should be properly placed, and pegged down with small forked sticks to prevent their rising up to the glasses, and also from crossing and entangling with each other; so that when they are properly directed at first, there will be no necessity of twisting and tumbling the plants afterward, which is always hurtful to them.

When the earth of the bed is laid the full thickness, it will be necessary to raise the frames, otherwise the glasses will be too close to the plants; but when this is done, there must be care taken to stop the earth very close round the side of the frame, to prevent the cold air from entering under them. The watering the plants, and admitting fresh air to them, must be diligently attended to, otherwise the plants will be soon destroyed; for a little neglect either of admitting air, or letting in too much, or by over watering, or starving the plants, will very soon destroy them past recovery.

When the fruit appears upon the plants, there will also appear many male flowers on different parts of the plant; these may at first sight be distinguished, for the female flowers have the young fruit situated under the flowers, but the male have none; but these have three stamina in their center with their summits, which are loaded with a golden powder. This is designed to impregnate the female flowers, and when the plants are fully exposed to the open air, the soft breezes of wind convey this farina or male powder from the male to the female flowers; but in the frames where the air is frequently too much excluded at this season, the fruit often drops off for want of it; and I have often observed, that bees that have crept into the frames when the glasses have been raised to admit the air, have supplied the want of those gentle breezes of wind, by carrying the farina of the male flowers on their hind legs into the female flowers, where a sufficient quantity of it has been left to impregnate them. For as the bees make their wax of the farina or male powder of flowers, they search all the flowers indifferently to find it; and I have observed them come out of some flowers with their hind legs loaded with it, and going immediately into other flowers which have none, they have scattered a sufficient quantity of this farina about the style of the female flowers, to impregnate and render them prolific. These insects have taught the gardeners a method to supply the want of free air, which is so necessary for the performance of this in the natural way. This is done by carefully gathering the male flowers, at the time when this farina is fully formed, and carrying them to the female flowers, turning them down over them, and with the nail of one finger, gently striking the outside of the male, so as to cause the powder on the summits to scatter into the female flowers, and this is found to be sufficient to impregnate them; so that by practising this method, the gardeners have now arrived at a much greater certainty than formerly, to procure an early crop of Cucumbers and Melons; and by this method the florists have arrived to greater certainty of procuring new varieties of flowers from

from seeds, which is done by the mixing of the farina of different flowers into each other.

When the fruit of the Cucumbers are thus fairly set, if the bed is of a proper temperature of warmth, they will soon swell, and become fit for use; so all that is necessary to be observed, is to water the plants properly, which should be done by sprinkling the water all over the bed, for the roots of the plants will extend themselves to the side of the bed; therefore those who are inclined to continue these plants as long as possible in vigour, should add a sufficient thickness of dung and earth all round the sides of the beds, so as to enlarge them to near double their first width; this will supply nourishment to the roots of the plants, whereby they may be continued fruitful great part of the summer; whereas, when this is not practised, the roots of the plants, when they have reached the side of the beds, are dried by the wind and sun, so that the plants languish and decay long before their time.

Those gardeners who are fond of producing early Cucumbers, generally leave two or three of their early fruit, which are situated upon the main stem of the plant near the root, for seed; which, when fully ripe, they carefully save to a proper age for sowing, and by this method they find a great improvement is made of the seed; and this they always use for their early crops only, for the succeeding crops do not deserve so much care and attention.

I have here only mentioned the method of raising the young Cucumber plants in stoves; for as these conveniencies are now pretty generally made in the curious kitchen-gardens in most parts of England, this method may be more universally practised; but in such gardens where there are no stoves, the seeds should be sown upon a well prepared hot-bed: and here it will be the best way to sow the seeds in small halfpenny pots, because these may be easily removed from one bed to another, if the heat should decline; or, on the contrary, if the heat should be too great, the pots may be raised up, which will prevent the seed or the young plants from being injured thereby. When the plants are come up as was before directed, there should be a fresh hot-bed prepared, with a sufficient number of halfpenny pots plunged therein ready to receive the plants, which must be planted into them in the same manner as was before directed, and the after-management of the plants must be nearly the same; but as the steam of the hot-bed frequently occasions great damps, there must be great care to turn and wipe the glasses frequently, to prevent the condensed moisture falling on the plants, which is very destructive to them. There must also be great attention to the admitting fresh air at all proper times, as also to be careful in keeping the bed to a proper temperature of heat; for as there is a want of fire to warm the air, that must be supplied by the heat of dung, afterward these plants must be ridged out in the same manner as before directed.

If the bed is of a good temper for heat, your plants will take root in less than twenty-four hours; after which time you must be careful to let in a little air at such times when the weather will permit, as also to turn the glasses upside down every day to dry; for the steam of the bed condensing on the glasses, will fall down upon the plants, and be very injurious to them; therefore whenever the weather is so bad as not to permit the glasses to lie turned long, you should at least turn them once or twice a day, and wipe off the moisture with a woollen cloth; but you must also be very careful how you let in too much cold air, which is equally destructive to the tender plants; therefore, to avoid this, it is a very good method to fasten before the upper side of the frame, where the air is suffered to enter the bed, a piece of coarse cloth or mat, so that the air which enters may pass through that, which will render it less injurious to your plants.

You must also be very cautious in giving water to the plants while young; and whenever this is done, it

should be sparingly, and the water should be placed either into a heap of dung, or in some other warm place, for some time before it is used, so as to be nearly of a temperature for warmth with the inclosed air of the hot-bed; and as the plants advance in height, you should have a little dry sifted earth always ready to earth up their shanks, which will greatly strengthen them. You must also be very careful to keep up the heat of the bed, which, if you should find decline, you must lay a little fresh litter round about the sides of the bed, and also keep the glasses well covered in the nights, or in bad weather: but if, on the other hand, your bed should prove too hot, you should thrust a large stake into the side of the dung in two or three places, almost to the middle of the bed, which will make large holes, through which the greatest part of the steam will pass off without ascending to the top of the bed; and when you find it has answered your purpose by slackening the heat of your bed, you must stop them up again with dung.

These directions, if carefully attended to, will be sufficient for raising the plants in the first bed: you must therefore, when you perceive the third, or rough leaf begin to appear, prepare another heap of fresh dung, which should be mixed with ashes, as was before directed; this should be in quantity according to the number of holes you intend to make. The common allowance for ridging out the earliest plants is, one load to each light or hole, so that the bed will be near three feet thick in dung; but for such as are not ridged out till March, two loads of dung will be sufficient for three holes, for I could never observe any advantage in making these beds so thick with dung as some people do; their crops are seldom better, if so good, as those which are of a moderate substance; nor are they forwarder, and the fruit is rarely so fair, nor do the Vines continue so long in health.

In making these beds, you must carefully mix the dung, shaking it well with the fork, so as not to leave any clods of dung unseparated, as also to beat it down pretty close, to prevent the steam from rising too hastily; you must also be careful to lay it very even, and to beat or press down the dung equally in every part of the bed, otherwise it will settle in holes, which will be very hurtful. When you finish laying the dung, you must make a hole exactly in the middle of each light, about a foot deep, and eight or nine inches over; these holes must be filled with light fresh earth, which should be screened to take out all large stones, clods, &c. laying it up in a hill; and in the middle of each thrust in a stick about eighteen inches long, which should stand as a mark to find the exact place where the hole is; then earth the bed all over about three inches thick, levelling it smooth, and afterwards set the frame upon it, covering it with glasses; but if there is any apprehension of the dung heating too violently, the earth should not be laid upon the bed until the heat is somewhat abated, which will be in a few days, and then the earth may be laid upon the bed by degrees, covering it at first two inches thick; and a week or ten days after another inch in thickness may be laid on, but there should be the whole thickness of earth laid upon the bed before the Vines begin to run; and if this thickness of earth is at last six or seven inches, the Vines will grow the stronger for its being so thick; for if the roots are observed, they will be found to spread and cover the whole bed as much as the Vines extend above; and when the earth is very shallow, or too light, the Vines will hang their leaves every day for want of a sufficient depth of earth to support their roots; so that if they are not constantly and well watered, they will not have strength to last long, nor to produce fair fruit; and the giving them too much water is not so proper, nor will it answer near so well, as the giving a depth of earth upon the dung.

In four or five days time your bed will be in fit order to receive your plants, of which you may easily judge by pulling out one of the sticks which was put in the middle

middle of the holes, and feeling the lower part of it, which will satisfy you what condition your bed is in; then you must stir up the earth in the middle of the hole with your hand, breaking all clods, and removing all large stones, making the earth hollow in form of a basin; into each of these holes you must plant two plants, in doing of which, observe to make the holes for the plants a little slanting towards the middle of the basin, especially if your plants are long shanked; this is intended to place the roots of the plants as far as possible from the dung, to which if they approach too near, the lower part of their roots is subject to be burned off; then settle the earth gently to each plant, and, if the earth is dry, it will be proper to give them a little water (which should be warmed to the temper of the bed, as was before directed;) and if the sun should appear in the middle of the day, they should be shaded therefrom with mats until the plants have taken root, which will be in two or three days; after which, you must let them enjoy as much of the sun as possible, observing to turn the lights in the day time to dry, as also to give a little air whenever the weather will permit.

You must also observe to keep the glasses covered every night, and in bad weather, but be very careful not to keep them covered too close, especially while the bed has a great steam in it, which will cause a damp to settle upon the plants, which, for want of air to keep the fluid in motion, will stagnate and rot them.

When your plants are grown to be four or five inches high, you must, with some slender-forked sticks, incline them toward the earth, each one a separate way; but this must be done gently at first, lest by forcing them too much, you should strain or break the tender vessels of the plants, which would be very hurtful to them. In this manner you should, from time to time, observe to peg down the runners as they are produced, laying each in exact order, so as not to interfere or cross each other; nor should you ever after remove them from their places, or handle them too roughly, whereby the leaves may be broken or displaced, which is also equally injurious to them; but whenever you have occasion to weed the bed between the plants, do it with great care, holding the leaves aside with one hand, while with the other you pull out the weeds.

In about a month after they are ridged out, you may expect to see the beginnings of fruit, which very often are preceded by male flowers, which many people are so ignorant as to pull off, calling them false blossoms; but this I am fully convinced, by many experiments, is wrong; for these flowers are of absolute service to promote the welfare of the fruit, which, when these male flowers are entirely taken off, does very often fall away, and come to nothing: nor should the Vines be pruned, as is too often the practice of unskilful people, especially when they are too luxuriant, which often happens when the seeds were fresh, or of the last year's sowing, and the plants in good heart. If this should happen to be the case, it would be very proper to pull up one of the plants, before they have run so far as to entangle with the other; for it often happens, that one or two plants are better than four or five, when they are vigorous; for when the frame is too much crowded with Vine, the fruit is seldom good, nor in such plenty, as when there is a more moderate quantity of shoots; for the air being hereby excluded from the fruit, they often decay, and fall off very young.

You must also be very careful to cover the glasses every night when your fruit begins to appear, as also to lay a little fresh litter, or mowing of grass round the sides of the bed, to add a fresh heat thereto; for if the heat of the bed be spent, and the nights prove cold, the fruit will fall away and come to nothing; and when the sun is extreme hot in the middle of the day, you must cover the glasses with mats to shade the Vines; for although they delight in heat, yet the direct rays of the sun, when it has great force,

are very injurious, by either scorching those leaves which are near the glasses, or by causing too great a perspiration, whereby the extreme part of the shoots and the large leaves are left destitute of nourishment, and the fruit will be at a stand, and often turn yellow before it arrives at half its growth; this is too often the case, when the beds have not a sufficient depth of earth over the dung.

At this time, when your Vines are spread so as to cover the hot-bed, it will be of great service when you water them, to sprinkle them all over gently so as not to hurt the leaves; but observe to do this not at a time when the sun is very hot, for hereby I have known a whole bed of Cucumbers spoiled; for the water remaining upon the surface of the leaves in drops, doth collect the rays of the sun as it were to a focus, and so scorches the leaves, that in one day's time they have, from a bright green, become of the colour of brown paper. The watering of the beds all over will be of great service, by giving nourishment to those roots, which by this time will have extended themselves all over the bed; and if the warmth of the bed should now decline, it will be of great service to add a lining of fresh dung round the sides of the beds, to give a new heat to them; for as the nights are often cold at this season, where the beds have not a kindly warmth left in them, the fruit will frequently drop off the Vines, when grown to the size of a little finger; and if upon this lining of dung there is a thickness of strong earth laid for the roots of the plants to run into, it will greatly strengthen them, and continue the plants in vigour a much longer time than they otherwise will do; for the roots of these plants extend to a great distance when they have room, which they cannot have in a bed not more than five feet wide; so that when they have no greater extent for their roots, the plants will not continue in vigour above five or six weeks, which, if they have a depth and extent of earth, will continue three months in bearing; so that where there are several beds made near each other, it will be the best way to fill up the bottom of the alleys between them with warm dung, and cover that with a proper thickness of earth, so as to raise them to the level of the beds. These directions, with diligent observation, will be sufficient for the management of this crop of Cucumbers; and Vines thus treated will continue to supply you with fruit till the beginning of July, by which time the second crop will come to bear; the sowing and managing of which is what I shall next proceed to. About the middle of March, or a little later, according to the earliness of the season, you must put in your seeds, either under a bell-glass, or in the upper side of your early hot-bed; and when the plants are come up, they should be pricked upon another moderate hot-bed, which should be covered with bell or hand-glasses, placed as close as possible to each other; the plants should also be pricked at about two inches distance from each other, observing to water and shade them until they have taken new root, which will be in a very short time. This is to be understood of such places where a great quantity of plants are required, which is constantly the case in the kitchen-gardens near London; but where it is only for the supply of a family, there may be plants enough raised on the upper side of the beds where the first crop is growing; or if the Vines should have extended themselves so far as to cover the whole bed, whereby there will not be room to prick the plants, a single light will contain a sufficient number of plants, while young, to plant out in ridges, as will supply the largest family with Cucumbers during the latter season. You must also cover the glasses with mats every night, or in very bad weather; but in the day time, when the weather is hot, you must raise the glasses with a stone on the opposite side from the wind, to give air to the plants, which will greatly strengthen them; you must also water them as you shall find they require it, but this must be done sparingly while the plants are young.

The middle of April the plants will be strong enough to ridge out, you must therefore be provided with a heap of new dung, in proportion to the quantity of holes you intend to plant, allowing one load to six holes. When your dung is fit for use, you must dig a trench about two feet four inches wide, and in length just as you please, or the place will allow; and if the soil be dry, it should be ten inches deep, but if wet, very little in the ground, levelling the earth in the bottom; then put in your dung, observing to stir and mix every part of it as was directed for the first hot-beds, laying it close and even.

When this is done, you must make holes about eight inches over, and six inches deep, just in the middle of the ridge, and three feet and a half distance from each other; and if there be more than one ridge, the distance of those ought to be eight feet and a half from each other; then fill the holes with good light earth, putting a stick into the middle of each for a mark, and afterwards cover the ridge over with earth about four inches thick, laying the earth the same thickness round the sides. When the earth is levelled smooth, you must set the glasses on upon the holes, leaving them close down about twenty-four hours, in which time the earth in the holes will be warmed sufficiently to receive the plants; then with your hand stir up the earth in the holes, making it hollow in form of a basin; into each of which you should plant three or four plants, observing to water and shade them until they have taken root; after which time you must be careful to give them a little air by raising the glasses on the opposite side to the wind, in proportion to the heat of the weather, as also to water them as you shall see they require it; but you must only raise the glasses in the middle of the day, until the plants fill the glasses, at which time you should raise the glasses with a forked stick on the south side, in height proportionable to the growth of the plants, that they may not be scorched by the sun; this also will harden and prepare the plants to endure the open air, but you should not expose them too soon thereto; for it often happens, that there are morning frosts in May, which are many times destructive to these plants when exposed thereto; it is therefore the surest method to preserve them under the glasses, as long as they can be kept in without prejudice to the plants; and if the glasses are raised with two bricks on the backside, and the forked stick on the other side, they may be kept in a great while without danger.

Towards the latter end of May, when the weather appears settled and warm, you should turn your plants down gently out of the glasses; but do not perform this in a very dry, hot, sunny day, but rather when there is a cloudy sky, and an appearance of rain; you must in doing of this raise the glasses either upon bricks, or forked sticks, whereby they may stand secure at about four or five inches high from the ground, that the plants may lie under them without bruising; nor should you take the glasses quite away till the latter end of June, or the beginning of July, for these will preserve the moisture much longer to their roots than if they were quite exposed to the open air; about three weeks after you have turned the plants out of the glasses, they will have made a considerable progress, especially if the weather has been favourable, at which time you should dig up the spaces of ground between the ridges, laying it very even; then lay out the runners of the Vines in exact order, and be careful in this work not to disturb the Vines too much, nor to bruise or break the leaves; this digging of the ground will loosen it, and thereby render it easy for the roots of the plants to strike into it, as also render the surface of the earth more agreeable to the Vines that run upon it. After this there will be no farther care needful, but only to keep them clear from weeds, and to water them as often as they shall require, which they will soon shew, by the hanging of their greater leaves. The ridges, thus managed, will continue to produce large quantities of fruit from June until the latter end of Au-

gust, after which time the coldness of the season renders them unwholesome, especially if the autumn prove wet.

From these ridges people commonly preserve their Cucumbers for seed, by making choice of two or three of the fairest fruit upon each hole, never leaving above one upon a plant, and that situated near the root of it; for if you leave more, they will weaken the plant so much, that your other fruit will be small, and fewer in number: but those persons who value themselves upon producing Cucumbers very early, commonly leave three or four Cucumbers of the first produce of their earliest crop, when the fruit is fair; and the seeds of these early fruit, are generally preferred to any other for the first crop. These should remain upon the Vines until the middle or end of August, that the seeds may be perfectly ripe; and when you gather them from the Vines, it will be proper to set the fruit in a row upright against a hedge or wall, where they may remain until the outer cover begins to decay; at which time you should cut them open, and scrape out the seeds, together with the pulp, into a tub, which should be afterwards covered with a board, to prevent filth from getting amongst the pulp. In this tub it should be suffered to remain eight or ten days, observing to stir it well with a long stick to the bottom every day, in order to rot the pulp, that it may be easily separated from the seeds; then pour some water into the tub, stirring it well about, which will raise the scum to the top, but the seeds will settle to the bottom; so that by two or three times pouring in water, and afterwards straining it off from the seeds, they will be perfectly cleared from the pulp; then you should spread the seeds upon a mat, which should be exposed to the open air three or four days until they are perfectly dry, when they may be put up in bags, and hung up in a dry place where vermin cannot come to them, where they will keep good for several years, but are generally preferred when three or four years old, as being apt to produce less vigorous, but more fruitful plants.

I shall, in the next place, proceed to give directions for managing Cucumbers for the last crop, or what are generally called picklers.

The season for sowing these is towards the latter end of May, when the weather is settled. The ground where these are commonly sown, is between Cauliflowers, in the wide rows, between which are allowed four feet and a half space when the Cauliflowers were planted. In these rows you should dig up square holes at about three feet and a half distance from each other, breaking the earth well with a spade, and afterwards smoothing and hollowing it in the form of a basin with your hand; then put eight or nine seeds into the middle of each hole, covering them over with earth about half an inch thick; and if it should be very dry weather, it will be proper to water the holes gently in a day or two after the seeds are sown, in order to facilitate their vegetation.

In five or six days, if the weather be good, your plants will begin to thrust their heads above ground; at which time you should be very careful to keep off the sparrows, which are very fond of the young tender seed-leaves of these plants; and, if they are not prevented, will destroy your whole crop: but as it is not above a week that the plants are in danger, it will be no great trouble to look after them during that time; for when the plants are come up, and have expanded their seed leaves, the sparrows will not meddle with them.

You must also be careful to water them gently, as you find the drought of the season may require; and when you perceive the third or rough leaf of the plants begin to appear, you must pull out all the weakest plants, leaving only three or four of the most promising and best situated in each hole, stirring the earth round about them with a small hoe to destroy the weeds, and raise the earth about the shanks of the plants, putting a little earth between them, pressing it gently down with your hand, that the plants may

may be thereby separated from each other to a greater distance; then give them a little water (if the weather be dry) to settle the earth about them, which you must afterwards repeat as often as you shall find it necessary, still being careful to keep the ground clear from weeds.

When your Cauliflowers are quite drawn off the ground from between the Cucumbers, you must hoe and clean the ground, drawing the earth up round each hole in form of a basin, the better to contain the water when it is given them; you must also lay out the plants in exact order as they are to run and extend, so that they may not interfere with each other; then lay a little earth between the plants left, pressing it down gently with your hand, the better to spread them each way, giving them a little water to settle the earth about them, repeating it as often as the season shall require, and observing to keep the ground clean from weeds. The plants thus managed, will begin to produce fruit toward the latter end of July, when you may either gather them young for pickling, or suffer them to grow for large fruit.

The quantity of holes necessary for a family, is about fifty or sixty; for if you have fewer, they will not produce enough at one gathering to make it worth the trouble and expence of pickling, without keeping them too long in the house, for you cannot expect to gather more than two hundred at each time from fifty holes; but this may be done twice a week during the whole season, which commonly lasts five weeks; so that from fifty holes you may reasonably expect to gather about two thousand in the season, which, if they are taken small, will not be too many for a private family. And if so many are not wanted, they may be left to grow to a proper size for eating.

CUCUMIS AGRESTIS. See **MOMORDICA**.

CUCURBITA. Lin. Gen. Plant. 968. Tourn Inst. R. H. 107. [so called from *Curvata*, *Lat.* bended, becau fethe fruit of this plant generally bends,] the Gourd.

The CHARACTERS are,

It hath male and female flowers in the same plant. The flowers have a bell-shaped empalement of one leaf, whose borders are terminated by five bristles; the flowers are bell-shaped, adhering to the empalement, and are of one petal, which is veined and rough, divided at the top into five parts. The male flowers have three stamina, which are connected at their extremity, but are distinct at their base, where they adhere to the empalement; these are terminated by linear summits running up and down. The female flowers have a large germen, situated under the flower, supporting a conical trifid style, crowned by a large trifid stigma. The germen afterward becomes a large fleshy fruit, having three soft membranaceous cells which are distinct, inclosing two rows of seeds which are bordered.

This genus of plants is ranged in the tenth section of Linnæus's twenty-first class, intitled *Monœcia Syngenesia*, the plants having male and female flowers on the same plant, and the stamina of the male flowers being connected.

The SPECIES are,

1. **CUCURBITA** (*Lagenaria*) foliis cordatis denticulatis tomentosis basi subtus biglandulosis; pomis lignosis. Lin. Sp. 1434. *Gourd with heart-shaped, indented, woolly leaves, having two glands at their base, and a ligneous shell to the fruit.* *Cucurbita longa*, folio molli, flore albo. J. B. 2. 221. *Commonly called the Long Gourd.*
2. **CUCURBITA** (*Pepo*) foliis lobatis, pomis lævibus. Lin. Sp. Plant. 1010. *Gourd with lobed leaves and a smooth fruit.* *Cucurbita major rotunda*, flore luteo, folio aspero. C. B. P. 213. *Commonly called Pumpkin, or Pompkin.*
3. **CUCURBITA** (*Verrucosa*) foliis lobatis, pomis nodoso-verrucosis. Lin. Sp. Plant. 1010. *Gourd with lobed leaves, and a warted knobby fruit.* *Cucurbita verrucosa*. J. B. 2. 222. *Warted Gourd.*
4. **CUCURBITA** (*Melopepo*) foliis lobatis, caule erecto, pomis depresso-nodoso. Lin. Sp. Plant. 1010. *Gourd with lobed leaves, an erect stalk, and a depressed knotty fruit.* *Melopepo clypeiformis*. C. B. P. 312. *Commonly called Squash.*

5. **CUCURBITA** (*Lignosus*) foliis lobatis asperis, flore luteo, pomis lignosis. *Gourd with rough-lobed leaves, a yellow flower, and fruit having a hard shell; commonly called Calabash.*

The first sort is sometimes propagated in the English gardens by way of curiosity, but the fruit is very rarely eaten here; though, if they are gathered when they are young, while their skins are tender, and boiled, they have an agreeable flavour. In the eastern countries these fruit are very commonly cultivated and sold in the markets for the table, and are a great part of the food of the common people, from June to October. These fruit are also eaten in both the Indies, where the plants are cultivated as culinary; and in those countries, where the heat of their summers is too great for many of our common vegetables, these may be a very good substitute.

This sort doth not vary like most of the others, but always produces the same shaped fruit; the plants of this extend to a great length, if the season proves warm and favourable, and will then produce ripe fruit; but in cold summers, the fruit seldom grows to half its usual size. I have measured some of these fruit when growing, which were six feet long, and a foot and a half round; the plants were near twenty feet in length: the stalks of this, and also the leaves, are covered with a fine soft hairy down; the flowers are large, white, and stand upon long foot-stalks, being reflexed at their brim; the fruit is generally incurved and crooked, and when ripe, is of a pale yellow colour. The rind of this fruit becomes hard, so that if the seeds and pulp are taken out, and the shell dried, it will contain water; and in those countries where they are much cultivated, are used for many purposes.

The second sort, which is commonly known by the title of Pumpkin, is frequently cultivated by the country people in England, who plant them upon their dunghills, where the plants run over them, and spread to a great distance; when the seasons are favourable, they will produce plenty of large fruit: these they usually suffer to grow to maturity, then they cut open a hole on one side, and take the seeds out of the pulp as clean as possible, after which they fill the shell with Apples sliced, which they mix with the pulp of the fruit, and some add a little sugar and spice to it; then bake it in an oven, and eat it in the same manner as baked Apples; but this is a strong food, and only fit for those who labour hard, and can easily digest it.

These may be propagated by sowing their seeds in April, on a hot-bed; and when the plants come up, they should be transplanted on another moderate bed, where they should be brought up hardily, and have a great deal of air to strengthen them; and when they have got four or five leaves, they should be transplanted into holes made upon an old dunghill, or some such place, allowing them a great deal of room to run, for some of the sorts will spread to a great distance. I have measured a single plant, which had run upwards of forty feet from the hole, and had produced a great number of side branches; so that if the plant had been encouraged, and all the side branches permitted to remain, I dare say it would have fairly overspread twenty rods of ground; which, to some people, may seem like a romance, yet I can affirm it to be fact. But what is this to the account printed in the Transactions of the Royal Society, which was communicated to them by Paul Dudley, Esq; from New England, wherein mention is made of a single plant of this kind, which, without any culture, spread over a large spot of ground, and from which plant were gathered two hundred and sixty fruits each, one with another, as big as a half peck.

There are several varieties of this fruit, which differ in their form and size; but as these are annually varying from seeds, so I have omitted the mentioning them, for they seldom continue to produce the same kinds of fruit three years together.

The

The third sort is very common in most parts of America, where it is cultivated as a culinary fruit; of this sort there are also several varieties, which differ in their form and size; some of these are flat, others round; some are shaped like a bottle, and others are oblong, their outer cover or rind being white when ripe, and covered with large protuberances or warts. The fruit are commonly gathered when they are half grown, and boiled by the inhabitants of America to eat as a sauce with their meat; but in England they are only cultivated by way of curiosity, few persons having a relish for them here, where they have a great variety of better esculent plants at that season, when these are fit for use. These may be propagated in the same manner as the second sort.

The fourth sort is also very common in North America, where it is cultivated for the same purposes as the third. This very often grows with a strong, bushy, erect stalk, without putting out runners from the side, as the other sorts, but frequently varies; for after it has been cultivated a few years in the same garden, the plants will become trailing like the others, and extend their branches to as great distance; and yet I have known when part of the seeds, taken out from the same fruit have been sown in another garden, at a considerable distance, the fruit have been the same, and the plants have grown erect, when those which were sown in the same garden, have produced trailing plants with larger fruit of a different shape.

The fruit of the fifth sort hath a hard shell when ripe like the first, which may be dried and preserved many years: these are of very different forms and size; some are shaped like a Pear, and are no bigger than a large Catherine Pear; some are as large as quart bottles, and almost of the same form; others are round and shaped like an Orange, and are of the same size and colour, but these are very variable; for I have cultivated most of the sorts near forty years, and have not been able, with all possible care, to preserve the varieties longer than two or three years in the same garden, without procuring fresh seeds from some distant place. Whether these changes are brought about by the admixture of the farina with each other, or from what cause I cannot say, because I have frequently planted them at as great distance from each other as I possibly could in the same garden, and yet the effect has been the same as when near.

The first sort requires to be treated more tenderly than the others, in order to procure ripe fruit; so the seeds should be sown upon a moderate hot-bed in April, and the plants afterward planted each into a penny pot, and plunged into a very moderate hot-bed to bring them forward; but they must not be tenderly treated, for if they have not a large share of free air admitted to them every day, they will draw up weak. When the plants are grown too large to be continued in the pots, there should be holes dug where they are designed to grow, and three or four barrows full of hot dung put into each; these should be covered with earth, into which the plants must be planted, and covered with hand-glasses till they run out.

There are some people who plant these plants by the sides of arbours, over which they train the vines; so that in a short time they will cover the whole arbour, and afford a strong shade, and upon some of these arbours I have seen the longest fruit. There are others who plant them near walls, pales, or hedges, to which they fasten the Vines, and train them to a great height: the Orange-shaped Gourd is the sort which is most commonly so planted for the ornament of its fruit, which has a pretty effect, especially when seen at some distance. All the sorts require a large supply of water in dry weather.

These plants requiring so much room to spread, and their fruit being very little valued in England, hath occasioned their not being cultivated amongst us; we having so many plants, roots, or fruits, which are

greatly preferable to those for kitchen uses: but in some parts of America, where provisions are not in so great plenty, or so great variety, these fruits may be very acceptable.

CUIETE See CRESCENTIA.

CULMIFEROUS PLANTS [so called of Culmus, Lat. straw or haulm,] are such as have a smooth jointed stalk, usually hollow, and at each joint wrapped about with single, narrow, sharp-pointed leaves; and their seeds are contained in chaffy husks, as Wheat, Barley, &c.

CUMINOIDES. See LAGOECIA.

CUMINUM. Lin. Gen. Plant. 313. Mor. Umb. Κύμινον, Gr. Cumin.

The CHARACTERS are,

It hath an umbelliferous flower; the general umbel is composed of smaller, which are divided into four parts; their involucre is longer than the umbel. The great umbel is uniform; the flowers have five unequal petals, whose borders are inflexed, and five single stamina, terminated by slender summits. It hath a large germen situated under the flower, supporting two small styles, crowned by single stigmas. The germen afterward becomes an oval striated fruit, composed of two oval seeds, which are convex and furrowed on one side, and plain on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

We have but one SPECIES of this genus, viz.

CUMINUM (*Cuminum*.) Lin. Mat. Med. 139. Cumin. *Cuminum semine longiore.* C. B. P. 146. *Cumin with a longer seed.*

This plant is annual, perishing soon after the seeds are ripe; it seldom rises more than nine or ten inches high; in the warm countries where it is cultivated; but I have never seen it grow more than three or four inches high in England, where I have sometimes had the plants come so far as to flower very well, but never to produce seeds. The leaves of this plant are divided into long narrow segments like those of Fennel, but much smaller; they are of a deep green, and generally turn backward at their extremity; the flowers grow in small umbels at the top of the stalks; these are composed of five unequal petals, which are of a pale bluish colour, and are succeeded by long, channelled, aromatic seeds.

The seeds of this plant is the only part used in medicine; these are ranged among the greater hot seeds; they consist of very warm dissolving parts, and are esteemed good to expel wind out of the stomach and bowels, so they are frequently put into clysters for that purpose, and are sometimes given in powder; and outwardly applied, they are of great service to ease the pains of the breast or side.

This plant is propagated for sale in the island of Malta, where it is called Cumino aigro, i. e. *bitter Cumin*. But Anise, which they also propagate in no less quantity, they call Cumino dulce, i. e. *sweet Cumin*. So that many of the old botanists were mistaken, when they made two species of Cumin, viz. *acre* and *dulce*.

If the seeds of this plant are sown in small pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed to bring up the plants, and these after having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preserving the balls of earth to their roots, and afterward kept clean from weeds, the plants will flower pretty well, and by thus bringing of the plants forward in the spring, they may perfect their seeds in very warm seasons.

CUNILA. See SIDERITIS.

CUNONIA. Buttn. Cun. tab. 1. Antholyza. Lin. Gen. Plant. 56.

The CHARACTERS are,

The flowers grow alternate in an imbricated spike, each having a spathe or sheath, composed of two spear-shaped concave leaves; the flower hath one ringent petal, having a short slender tube, which is dilated at the chaps, and compressed on the sides; the upper lip is arched, and stretched

C U N

stretched out a considerable length beyond the ale or wings, and is rounded at the top: it hath three long slender stamina, which are situated in the upper lip, terminated by oblong flat summits, which are fastened in their middle and lie prostrate. It hath a slender style, which is shorter than the stamina, crowned by three cylindrical stigmas which join the summits, and are included in the upper lip. The germen, which is situated below the flower, becomes an oblong capsule with three cells, filled with compressed seeds.

This genus of plants is ranged in the first section of Linnæus's third class, intitled Triandria Monogynia, the flowers having three stamina and one style, but he has joined it to the Antholyza, making it only a species of that genus; whereas by the form and characters of the flower, it should be separated from that, there being full as great difference between the flowers of this and those of the Antholyza, as is between those and the Gladiolus; for the flowers of Cunonia have no carina or under lip, but those of the Antholyza have, in which one of the stamina is included, which is separated from the other two, which are situated in the upper lip; but in this all three are of equal length, and situated in the hollow of the upper lip. The two wings of this are short, whereas those of Antholyza are long, so that I think they should be separated.

We have but one SPECIES of this genus at present in the English gardens, which is

CUNONIA (*Antholyza*) floribus sessilibus, spathis maximis.

Buttn. Cun. 211. tab. 1. *Cunonia with flowers sitting close to the stalk, and very large spathæ or sheaths.* Dr. Linnæus titles it *Antholyza staminibus omnibus adscendentibus*. Sp. Plant. 37. *Antholyza with all the stamina ascending.*

There is a plant of this kind figured in Cornutus's book of Canada plants, under the title of Gladiolus Æthiopicus, flore Coccineo, p. 78. but by his figure and description, it appears to be a different species from this, his flowers having much smaller spathæ or sheaths, nor does the stalks of his rise near so high as this; there are also some other differences between them.

The seeds of this plant I received from the Cape of Good Hope, where it grows naturally, which succeeded so well in the Chelsea garden, as to produce a great number of plants, which flowered well the third season after they appeared, and have continued to produce flowers, and perfect their seeds every year since.

This hath a compressed bulbous root, somewhat like that of Corn Flag, covered with a brown skin; from this arise several narrow sword-shaped leaves, about nine inches long, and a quarter of an inch broad in the middle, terminating in acute points; these have one longitudinal midrib which is prominent, and two longitudinal veins running parallel on each side; they are of a sea-green colour, and appear in autumn, growing in length all the winter; in spring the stalk arises from between the leaves, which is round, strong, and jointed; at each joint is situated a single leaf, which almost embraces the stalk for near three inches from the base, then by the curvature of the stalk it is separated, standing erect: the stalks rise near a foot and a half high, which is generally curved two opposite ways; the upper part of the stalk is terminated by a loose spike of flowers, coming out of large spathæ or sheaths, composed of two oblong concave leaves, terminating in acute points: these are at their first appearance placed imbricatum over each other, but as the stalk increases in length, so these are separated; from between these two leaves comes out the flower, each having a slender Saffron-coloured tube near half an inch long, which is then enlarged where the petal is divided, and the upper segment is extended two inches in length, being arched over the stamina and style. This is narrow as far as to the extent of the wings, but above them is enlarged and spread open half an inch in length, and is concave, covering the summits and stigmas

C U P

which are extended to that length; the two wings are also narrow at their base, but are enlarged upward in the same manner, ending in concave obtuse points, which are compressed together, and cover the stamina and style. This flower is of a beautiful soft scarlet colour, so makes a fine appearance, about the latter end of April or beginning of May, which is the season of its flowering. After the flowers decay, the germen becomes an oval smooth capsule, opening in three cells, which are filled with flat bordered seeds.

This plant is too tender to thrive in the open air in England, so the roots must be planted in pots filled with light earth, and may remain in the open air till October, when they must be removed into shelter, either into an airy glass-case, or placed under a hot-bed frame, where the leaves will keep growing all winter, and in the spring the stalks arise and flower. During the winter season, the plants will require a little water when the weather is mild, once a week, but it must not be given in great quantities, especially in cold weather; in the spring they should be watered oftener; and when the flowers are past, the pots should be removed into the open air to perfect their seeds, which will ripen the latter end of June, soon after which the stalks will decay to the root, which will remain inactive till September. When the stalks are decayed, the roots may be taken out of the ground, and kept in a dry room till the end of August, when they should be planted again. This plant is easily propagated by offsets, which it sends out in great plenty, or by sowing of the seeds, which should be sown in pots about the middle of August, and placed in a situation where they may enjoy the morning sun, and in dry weather should be gently watered; in September the pots may be removed to a warmer situation, and in October they must be placed under a frame, where they may be protected from frost and hard rains, but in mild weather enjoy the free air. The plants will appear in October, and continue growing all the winter, and in June their leaves will decay; then they may be taken up, and four or five roots may be planted in each pot, till they have grown another year, when they may be each put into a separate pot. These seedling plants must be sheltered in the same manner as the old roots in winter, and the third year they will flower.

CUPRESSUS. Lin. Gen. Plant. 958. Tourn. Inst. R. H. 587. tab. 358. Cypress [takes its name either of κύω, to bring forth, and πάριος, because it produces equal branches on both sides; or of Cyparissus, a certain infant whom the poets feign to have been transformed into a Cypress-tree.] The Cypress-tree.

The CHARACTERS are,

It hath male and female flowers growing at distances on the same plant; the male flowers are formed into oval catkins, in which the flowers are placed thinly, among several roundish scales, each having a single flower. These have no petals nor stamina, but have four summits which adhere to the bottom of the scales. The female flowers are formed in a roundish cone, each containing eight or ten flowers; the scales of the cones are opposite, each having a single flower, these have no petals; the germen is scarce visible, but under each scale there are many punctures or spots, and a concave truncated apex instead of a style; this afterward becomes a globular cone, opening in angular target-shaped scales, under which are situated angular seeds.

This genus of plants is ranged in the ninth section of Linnæus's twenty-first class, intitled Monœcia Monadelphia; the plants of this section have male and female flowers on the same plant, and the male flowers are joined in one bdy.

The SPECIES are,

1. CUPRESSUS (*Sempervirens*) foliis imbricatis, ramis erectioribus. Cypress with imbricated leaves, and upright branches. Cupressus metâ in fastigium convolutâ qua fœmina. Plinii. Dod. Pempt. 856. Female or common upright Cypress.

2. CUPRESSUS (*Horizontalibus*) foliis imbricatis acutis, ramis horizontalibus. *Cypress with imbricated acute leaves, and branches growing horizontally.* Cupressus ramos extra se spargens quæ Mas. Plinii. Tourn. Inst. R. H. 587. *Male spreading Cypress.*
3. CUPRESSUS (*Lusitanica*) foliis imbricatis, apicibus aculeatis, ramis dependentibus. *Cypress with imbricated leaves terminating in spines, and branches hanging downward.* Cupressus Lusitanica, patula, fructu minore. Inst. R. H. 587. *Portugal spreading Cypress with a smaller fruit.*
4. CUPRESSUS (*Disticha*) foliis distichis patentibus. Hort. Cliff. 409. *Cypress with leaves on two sides the branches.* Cupressus Virginiana foliis Acaciæ deciduis. Hort. Amst. t. p. 113. *Virginia Cypress which sheds its leaves, commonly called Deciduous Cypress.*
5. CUPRESSUS (*Thyoides*) foliis imbricatis, frondibus ancipitibus. Lin. Sp. Plant. 1003. *Cypress with imbricated leaves, and branches standing two ways.* Cupressus nana Mariana, fructu cæruleo parvo. Pluk. Mant. 61. *Dwarf Maryland Cypress with a small blue fruit.*
6. CUPRESSUS (*Africana*) foliis linearibus simplicibus cruciatim positis. *Cypress with narrow single leaves placed crossways.* Cupressus Africana of Herman and Oldenburgh. *African Cypress-tree, called by the Dutch Cypress Boom.*

The first of these trees is very common in most of the old gardens in England, but at present is not so much in request as formerly, though it is not without its advantages; nor should it be entirely rejected, although many persons are of that opinion; for it serves to add to the beauty of wildernesses, or clumps of Evergreens, and where they are properly disposed, they have their beauties. It was formerly planted in borders of pleasure-gardens, and kept shorn into a pyramidal or conic form; and some people, believing them subject to be killed if they cut them, tied them up with cords into a pyramidal figure, which form they are naturally disposed to grow in; but this winding them about, prevented the air from entering the inward parts of the branches, so that the leaves decayed, and became unfightly, and greatly retarded their growth. And those which are sheared, if the operation is not performed in the spring, or early in the summer, are very subject to be injured by sharp winds and cuttings frosts in winter. Wherefore, upon the whole, I think it much better to suffer them to grow wild as they are naturally disposed, planting them only amongst other Evergreen Trees, where, by the darkness of their green leaves, together with their waving heads, they will greatly add to the variety.

The second sort is by far the largest growing tree, and is the most common timber in some parts of the Levant. This, if planted upon a warm, sandy, gravelly soil, will prosper wonderfully; and though the plants of this sort are not so finely shaped as those of the first, yet they greatly recompense for that defect, by its vigorous growth and strength, in resisting all weathers. This tree is very proper to intermix with Evergreens of a second size next to Pines and Firs, to form clumps; in which class it will keep pace with the trees of the same line, and be very handsome. Besides, the wood of this tree is very valuable, when grown to a size fit for planks, which I am convinced it will do in as short a space as Oaks; therefore, why should not this be cultivated for that purpose, since there are many places in England where the soil is of a sandy or gravelly nature, and seldom produces any thing worth cultivating? Now, in such places these trees will thrive wonderfully, and greatly add to the pleasure of the owner, while growing, and afterwards render as much profit to his successors, as perhaps the best plantation of Oaks; especially should the timber prove as good here, as in the islands of the Archipelago, which I see no reason to doubt of; for we find it was so gainful a commodity to the island of Candia, that the plantations were called *Dos Filix*, the felling of one of them being reckoned a daughter's portion.

The timber of this tree is said to resist the worm, moth, and all putrefaction, and is said to last many hundred years. The doors of St. Peter's church at Rome were framed of this material, which lasted from the great Constantine to Pope Eugenius IVth's time, which was eleven hundred years, and were then found and entire, when the Pope would needs change them for gates of brass. The coffins were made of this material, in which Thucydides tells us the Athenians used to bury their heroes; and the mummy chests, brought with those condited bodies out of Egypt, are many of them of this material.

This tree is by many learned authors recommended for the improvement of the air, and a specific for the lungs, as sending forth great quantities of aromatic and balsamic scents; wherefore many of the antient physicians of the Eastern countries used to send their patients, who were troubled with weak lungs, to the island of Candia, which at that time abounded with these trees, where, from the effects of the air alone, very few failed of a perfect cure.

The fourth sort is a native of America, where it grows in watery places, and rises to a prodigious height, and is of a wonderful bulk. I have been informed, that there are trees of this kind in America which are upwards of seventy feet high, and several fathoms in circumference, which trees grow constantly in the water; therefore they may probably be of singular advantage to plant in such swampy or wet soils, where few other trees will grow, especially of the resinous kind. That they are very hardy in respect to cold, is evident, from some few trees of this kind which were formerly planted in England; particularly one in the gardens of John Tradescant, at South Lambeth, near Vaux-Hall, which is upwards of thirty feet high, and of a considerable bulk, which, though in a common yard at present, where no care is taken of it, but, on the contrary, many hooks are driven into the trunk, to fasten cords thereto for drying of cloaths, yet the tree is in great health and vigour, but hath not produced any fruit as yet, which may be occasioned for want of moisture: for we often see many aquatic plants will grow upon a drier soil, but yet are seldom so productive of either flowers or fruit, as those which remain growing in the water.

There is also a pretty large tree of this kind now growing in the gardens of the late Sir Abraham Janssen, Bart. at Wimbleton in Surry, which has produced great quantities of cones for some years past, which, in favourable seasons come to maturity, and the seeds have been as good as those which have been brought from America. This tree was transplanted when it was very large, which has stunted its growth; which, together with its being planted upon a dry soil, may have occasioned its fruitfulness, for it has made very little progress in its growth since it was removed.

These trees are all propagated from seeds, which should be sown early in the spring on a bed of warm, dry, sandy earth, which must be levelled very smooth; then sow the seeds thereon pretty thick, sifting the same light earth over them half an inch thick. If the weather should prove very warm and dry, it will be proper to shade the bed from the sun in the day-time, and water the bed, which must be done very carefully, observing not to wash the seeds out of the ground. In about two months time (if your seeds are good) the young plants will appear above ground, which must be constantly kept clean from weeds, and in very dry weather should be often refreshed with water; but this should be done with great caution, lest you beat these tender rooted plants out of the ground. If the seeds are sown upon a moderate hot-bed, and the bed covered with mats, they will come up much sooner, and with greater certainty, than when they are sown in the cold ground.

In this bed the young plants may remain two years, by which time they will have strength enough to be transplanted into a nursery; but while the plants are young, they are tender, so should be covered in severe frost with mats to prevent their being injured thereby.

C U P

thereby. The best season for removing them is in the beginning of April, when the drying easterly winds of March are over, and, if possible, choose a cloudy day, when it is inclinable to rain; and in taking them out of the seed-bed, preserve the roots as entire as possible, and, if you can, a ball of earth to each plant. The soil in which these trees should be planted (as I before said) should be, for the two first sorts, a warm sand or gravel, which, when you have prepared, by carefully digging and cleansing from all noxious weeds, you must lay level. Then draw the lines where the trees are to be planted at three feet asunder, and plant the trees at eighteen inches distance in the rows, observing to close the earth well to their roots, as also to lay a little mulch upon the surface of the ground about their stems; and water them well to settle the earth to their roots, which should be repeated twice a week, until the plants have taken fresh root.

These plants may remain in the nursery three or four years, according to the progress they make, or till your ground is ready where they are to be planted: but if you intend to let them remain longer, you should take up every other tree in the rows, and transplant out; for otherwise their roots will be matted together, so that it will render it difficult to transplant them, as also endanger the future growth of the trees. The plants should by no means be let stand too long in the nursery before they are transplanted out for good, because the roots do not mat together so closely as those of many other sorts of Evergreen Trees, whereby they may be taken up with good balls of earth to their roots; but the roots of the Cypress are apt to extend out in length, so it is one of the most difficult trees to remove when grown large; therefore most curious persons choose to plant the young plants into small pots, when they first take them out of the seed-bed, and so train them up in pots two or three years, until they are fit to plant out where they are to stand for good, and, by this management, they are secure of all the plants; for these may be shaken out of the pots at any time of the year without danger, and planted with their whole ball of earth, which is likewise a great advantage. When they are planted out for good (if they are designed for timber) they should be planted about twelve or fourteen feet distance every way, and be very careful in removing those in the full ground, not to shake the earth from their roots; to prevent which, you should open the ground about each tree, cutting off all long roots, then working under the ball of earth, cut the downright roots off; and after having pared off all the earth from the upper part of the ball, as also reduced the bulk of it, so that its weight may not be too great for the fibres to support, they may be carried upon a handbarrow by two persons to the place where they are to be planted; but if they are to be carried to a distant place, they should either be put into baskets, or their roots closely matted up. When they are planted, you must settle the earth close to their roots as before, laying a little mulch upon the surface of the ground about their stems, to prevent the sun and wind from entering the earth to dry their fibres; and water them well, to settle the ground to their roots, which must also be repeated, if the weather proves dry, until they have taken root, after which time they will require little more care than to keep them clear from weeds.

The first, which is the most common sort in England, seldom produces good seeds in this country; it is therefore the best way to have the cones brought over entire from the south parts of France and Italy, where they ripen perfectly well, and take the seeds out just before you sow them, for they will keep much better in the cones than if they are taken out. The method to get the seeds out is to expose the cones to a gentle heat, which will cause them to open, and easily emit their seeds.

The second sort grows naturally in the Levant, and from thence it has been formerly brought to Italy, but

C U P

at present this is pretty rare in England; for what has passed under this title here, is only a variety of the common sort, whose branches grow much looser, and not so upright as the first; but the cones taken from these trees, and the seeds sown, have frequently produced plants of both varieties; but the true spreading Cypress extends its branches horizontally from the first year, and continues to extend them to a great length as the plants advance, and the plants raised from the seeds do not vary, so that it is certainly a distinct species. This grows to be a large timber tree in the Levant, and in Italy there are some of a considerable size.

The Virginian kind may also be propagated in as great plenty, for the cones of this may be easily procured from Carolina or Virginia, in both which places they grow in great abundance; and the seeds will rise as easily as any of the other sorts, and the plants are equally as hardy: these have been formerly kept in pots, and housed in winter, with which management they have not succeeded so well as they have done in England, since people have planted them into the full ground; and where they have had a moist soil, I have observed them to thrive best, which is since confirmed by Mr. Catesby, in his Natural History of Carolina; where he says, that this tree grows in places where the water commonly covers the surface of the ground three or four feet, so that it may be a very great improvement to our boggy soils. This tree, casting its leaves in winter, does not so well suit with plantations of Evergreens at that season; though, in summer, when there is the greatest pleasure in walking among plantations of trees, it hath so much the appearance of an Evergreen, as to pass for such. It may also be propagated by cuttings, which should be planted in a bed of moist earth in the spring before they begin to shoot.

The third sort is at present pretty rare in the English gardens, though of late years there have been many plants raised here; but this sort is not quite so hardy, I fear, as the common Cypress, for the plants are frequently killed, or greatly injured in severe winters; and in the hard frost in 1740, there was a large tree of this kind entirely killed in the gardens of his Grace the Duke of Richmond, at Goodwood in Sussex, which had been growing there several years; and in the year 1762, many large trees were killed. There are great plenty of these trees growing at a place called Busaco, near Coëmbra in Portugal, where this tree is called the Cedar of Busaco; and there it grows to be a timber tree, so that from thence the seeds may be easily procured.

This tree grows naturally at Goa, from whence it was first brought to Portugal, where it has succeeded, and been propagated; formerly there were some trees of this sort growing in the Bishop of London's garden at Fulham, where it passed under the title of Cedar of Goa, by which it was sent from thence to the Leyden garden with that name.

The fifth sort is a native of North America, where it grows to a considerable height, and affords an useful timber to the inhabitants for many purposes. This sort is extremely worth cultivating in England; for as it grows in a much colder country, there is no danger of its thriving well in the open air in England; and being an Evergreen of regular growth, will add to the variety of wilderness quarters, or other plantations of Evergreen Trees.

This sort is propagated by seeds, which should be sown in the spring in boxes or tubs filled with light fresh earth, and placed where they may enjoy the morning sun till eleven or twelve o'clock. In dry weather they should be duly watered, and constantly kept clear from weeds. In this situation they may remain till Michaelmas, when they should be removed to a warmer place; for the plants seldom appear till the following spring, so that it will be proper to place the boxes or tubs near a south wall, pale, or hedge, during the winter season; lest, by being too much shaded, the wet of the winter season should rot the

the seeds. In the spring following, if these tubs or boxes are placed on a moderate hot-bed, it will bring up the plants very soon, and greatly forward their growth; but as the spring advances, they should be inured to bear the open air by degrees; and in May they must be taken out of the hot-bed, and placed in a sheltered situation, where they may enjoy the morning sun, being careful to keep them clear from weeds, as also to water them duly in dry weather. The following winter it will be proper to remove the tubs near a south wall or pale, for the plants being very young, are sometimes tenderer than they will be afterward. Toward the latter end of March, or the beginning of April, just before the plants begin to shoot, they should be carefully taken up out of the boxes; and having prepared a bed or two (according to the quantity of plants raised) of fresh earth in a sheltered situation, the plants should be planted therein in rows about eighteen inches asunder, and about a foot distance plant from plant in the rows. This work should be done in cloudy weather, when there is rain; for in dry weather, when easterly winds commonly blow at this season, it will be very dangerous to transplant these plants; so that it had better be deferred a fortnight longer, till there is an alteration of the weather, than hazard the plants. When the plants are planted, they should be watered to settle the earth to their roots; and then the surface of the ground should be covered with mulch, to prevent the sun and wind from penetrating to the roots of the plants; for nothing is more injurious to these plants, than to have their fibres dried when they are transplanted; therefore the plants should not be taken out of the tubs till you are ready to place them in the ground, for they will not bear to lie out of the ground any time without great danger.

The branches of this tree are garnished with flat evergreen leaves, resembling those of the Arbor Vitæ; and the cones are no larger than the berries of the Juniper, from which they are not easily distinguished at a little distance; but upon closely viewing, they are perfect cones, having many cells like those of the common Cypress. If these trees are planted in a moist strong soil, they make very great progress, and may, in such situations, become profitable for timber; but however this tree may succeed for timber, yet it will be a great ornament to large plantations of evergreen trees, especially in such places where there is naturally a proper soil for them; because, in such situations, there are not many sorts of Evergreen Trees which thrive well, especially in cold places, and by increasing the number of sorts of these Evergreens, we add to the beauty of our gardens and plantations.

The third sort sends forth its branches almost horizontally, so that they extend to a great distance every way, and the trees are generally furnished with branches from the ground upward; but as these grow without much order, the trees have a very different appearance from all the other sorts. This grows to be a large timber tree in Portugal, but the largest tree which I have seen in England, has not been above fifteen feet high, and the side branches of this were extended more than eight feet on every side from the stem. This sort may be propagated from seeds in the same manner as the common Cypress, and the plants should be treated in the same manner as hath been directed for them, with this difference only, that it will be proper to cover these plants during the two first winters after they are come up, especially if the frost should be severe, which might destroy them, if they are exposed to it while they are young. This sort may also be propagated by cuttings, which, if planted in autumn, and screened in winter, they will take root; but it is generally two years before they will be rooted enough to transplant, nor will the plants so raised thrive so fast as the seedlings; therefore, when the seeds can be obtained, that is the best method to propagate this tree. The American deciduous Cypress may also be propagated by cuttings, as

I have several times tried; so that when seeds cannot be had, this method may be practised successfully. I suppose the common sort will also take from cuttings; but this I have not experienced, so cannot recommend it to practice.

These trees are so very ornamental to gardens, that no large garden can be compleat without many of them; and it is to these trees that the Italian villas owe a great share of their beauty, for there is no tree so proper to place near buildings; the pyramidal upright growth of their branches affords a picturesque appearance, and obstructs not the view of the building, and the dark green of their leaves make a fine contrast with the white of the building; so that, wherever there are temples or other buildings erected in gardens, there is no sort of tree so proper to place near them as these. In all the landscapes of Italian villas, we see many Cypress-trees represented; which have a very agreeable effect in the picture; and the trees, when rightly disposed in a garden, afford a no less agreeable prospect.

The seeds of the sixth sort were sent me from the Cape of Good Hope, where the trees grow naturally, and by the account which I received with the seeds, the cones of the tree are black when ripe. The young plants which I have raised from these seeds have loose spreading branches, which are closely garnished with narrow strait leaves, which come out opposite, and are alternately crossing each other; these are near one inch long, and of a light green colour; they continue in verdure all the year. These plants being young, are too tender to thrive in the open air in England as yet; but when they have obtained more strength, it is very probable they may do well in warm situations. I had two of these plants growing in the full ground, which were killed in the winter 1756. But those which were placed under a frame, where there were no covering of glass, and only wooden shutters, were not injured by the cold, though the earth of the pots was frequently hard frozen.

CURCUMA. Lin. Gen. Plant. 6. Cannacorus, Tourn. Inst. R. H. 367. Turmeric.

The CHARACTERS are,

The flowers have each several spathe, which are single and drop off; the flower hath one petal with a narrow tube, which is cut at the brim into three segments; it hath an oval-pointed nectarium of one leaf, which is inserted in the sinus of the largest segment of the petal; it hath five stamina, four of which are barren, and one fruitful, which is situated within the nectarium, and hath the appearance of a petal, having a bifid point, to which the summit adheres. It hath a roundish germen situated under the flower, supporting a style the length of the stamina, crowned by a single stigma. The germen afterward becomes a roundish capsule, having three cells, which are filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's first class, intitled Monandria Monogynia, the flower having one stamina and one style.

The SPECIES are,

1. CURCUMA (*Rotunda*) foliis lanceolato-ovatis, nervis lateralibus rarissimis. Lin. Sp. Plant. 2. *Curcuma with spear-shaped oval leaves, having very few nerves on the sides.* Curcuma radice rotundâ. C. B. Turmeric with a round root.

2. CURCUMA (*Longa*) foliis lanceolatis nervis lateralibus numerosissimis. Lin. Sp. Plant. 2. *Curcuma with spear-shaped leaves, having many lateral veins.* Curcuma radice longâ. H. L. 288. Turmeric with a long root.

The first sort hath a fleshy jointed root somewhat like that of Ginger, but rounder, which sends up several spear-shaped oval leaves, that rise upwards of a foot high; these have one longitudinal midrib, and a few transverse nerves running from the midrib to the sides; they are of a sea-green colour; from between these arise the flower-stalk, supporting a loose spike of flowers of a pale yellowish colour, inclosed in several different spathe or sheaths, which drop off. These flowers are never succeeded by seeds in the gardens here.

The

The second sort hath long fleshy roots; of a deep yellow colour, which spread under the surface of the ground like those of Ginger; they are about the thickness of a man's finger, having many round knotty circles, from which arise four or five large spear-shaped leaves, standing upon long foot-stalks; they have a thick longitudinal midrib, from which a numerous quantity of veins are extended to the sides; these leaves are of a glaucous or sea-green colour. The flowers grow in loose scaly spikes on the top of the foot-stalks, which arise from the larger knobs of the roots, and grow about a foot high; they are of a yellowish red colour, and shaped somewhat like those of the Indian Reed.

These plants grow naturally in India; from whence the roots are brought to Europe for use. They are very tender, so will not live in this country, unless they are placed in a warm stove. As they do not produce seeds in England, they are only propagated by parting their roots: the best time for removing and parting these roots is in the spring, before they put out new leaves; for the leaves of these plants decay in autumn, and the roots remain inactive till the spring, when they put out fresh leaves. The roots should be planted in rich kitchen-garden earth, and the pots should be constantly kept plunged in a bark-bed in the stove. In the summer season, when the plants are in a growing state, they will require to be frequently refreshed with water, but it should not be given to them in large quantities; they should also have a large share of air admitted to them in warm weather. When the leaves are decayed, they should have very little wet, and must be kept in a warm temperature of air, otherwise they will perish. These plants usually flower in August, but it is only the strong roots which flower, so they must not be parted into small roots, where the flowers are desired.

CURRAN-TREE. See RIBES.

CURURU. See PAULLINIA.

CUSPIDATED PLANTS [so called, of cuspis, Lat. the point of a spear] are such plants, the leaves of which are pointed like a spear.

CUSTARD-APPLE. See ANNONA.

CYANELLA. Royen.

The CHARACTERS are,

The flower has no empalement; it hath six oblong, concave, spreading petals, which join at their base, the three lower hanging downward, with six short spreading stamens, terminated by oblong erect summits, and a three-cornered obtuse germen, supporting a slender style the length of the stamens, having an acute stigma. The germen afterward becomes a roundish capsule, having three furrows, with three cells, inclosing many oblong seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, the flower having six stamens and one style.

We know but one SPECIES of this genus, viz.

CYANELLA (*Capensis*). Lin. Sp. 443. Cape Cyanelle.

This plant grows naturally at the Cape of Good Hope. The root is shaped like those of the Spring Crocus; the leaves are long, narrow, and have a sulcus on their upper side; the foot-stalk of the flower arises immediately from the root, supporting one flower with six petals, of a fine blue colour, which appears in May, but the flowers have not been succeeded by seeds as yet in England.

It is too tender to thrive in the full ground in this country, therefore the roots should be planted in pots filled with light earth; and in winter must be placed in a frame, and treated in the same manner as is directed for Ixia, with which the plant will thrive and produce flowers annually.

CYANUS. See CENTAURIA.

CYCAS, the Sago-tree.

There are several small plants of this sort in the English gardens, but from these no characters of the tree can be drawn; nor are there any just accounts of these to be met with in the several authors who have figured and described the tree.

We know but one SPECIES of it at present, viz. *Cycas (Circinalis) frondibus pinnatis circinalibus, foliis linearibus planis*. Lin. Sp. 1658. *Sago-tree with full branches, whose wings are placed circularly, and the small leaves are plain*. Arbor Zagoe Amboinensis. Seb. Thes. 1. p. 39.

This tree has been ranged in the tribe of Palms, to which it has great affinity, especially by its outer appearance the branches and trunk having the same structure.

This tree requires to be plunged into tanners bark in a stove, which should be kept up full to temperate heat in winter; but in summer should be much warmer, when it should be frequently refreshed with water during hot weather; but in autumn and winter it should be given sparingly.

Most of the plants of this kind now in the English gardens, have been communicated to the possessors by Richard Warner, Esq; of Woodford, in Essex, who received a tree of this sort, which was brought from India by the late Captain Hutchenson; but his ship being attacked by the French near home, the head of the tree was shot off, but the stem being preserved, put out several heads, which being taken off, produced so many plants.

CYCLAMEN. Lin. Gen. Plant. 184. Tourn. Inst. R. H. 154. tab. 68. Cyclamen; in French, *Pain de Pourreau*. [*Κυκλάμιον*], of *Κύκλος*, Gr. a circle, because the root of this plant is orbicular; it is called Sowbread, because the root is round like a loaf, and the sows eat it]. Sowbread.

The CHARACTERS are,

The flower hath a roundish permanent empalement of one leaf, divided into five parts at the top. It hath one petal with a globular tube, which is much larger than the empalement; the upper part is divided into five large segments, which are reflexed; it hath five small stamens situated within the tube of the petal, terminated by acute summits, which are connected in the neck of the tube. It hath a roundish germen, supporting a slender style, which is longer than the stamens, and crowned by an acute stigma. The germen afterward becomes a globular fruit with one cell, opening in five parts at the top, inclosing many oval angular seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamens and one style.

The SPECIES are,

1. CYCLAMEN (*Europæum*) foliis hastato-cordatis angulatis. Cyclamen with spear-pointed heart-shaped leaves, which are angular. Cyclamen hederæ folio. C. B. P. 306. Sowbread with an Ivy leaf.
2. CYCLAMEN (*Purpurascens*) foliis orbiculato-cordatis, infernè purpurascens. Cyclamen with round heart-shaped leaves, purple on their under side. Cyclamen orbiculato folio infernè purpurascens. C. B. P. 308. Round-leaved Sowbread with a purple under side.
3. CYCLAMEN (*Persicum*) foliis cordatis serratis. Cyclamen with sawed heart-shaped leaves; or Persian Cyclamen.
4. CYCLAMEN (*Vernale*) foliis cordatis angulosis integris. Cyclamen with heart-shaped angular leaves which are entire. Cyclamen hyeme & vere florens folio anguloso amplo, flore albo, basi purpurea, Persicum dictum. H. R. Par.
5. CYCLAMEN (*Orbiculatum*) radice inæquali, foliis orbiculatis. Cyclamen with an unequal root and round leaves. Cyclamen radice castaneæ magnitudinis. C. B. P. 308.
6. CYCLAMEN (*Coum*) foliis orbiculatis planis, pediculis brevibus floribus minoribus. Sowbread with orbicular plain leaves, shorter foot-stalks and smaller flowers. Cyclamen Hyemale, orbiculatis foliis infernè rubentibus, purpurascens flore Coum Herbariorum. H. R. Par.

The first sort is the most common in the English gardens. This grows naturally in Austria, Italy, and other parts of Europe, so will thrive in the open air in England, and is never killed by the frost. It hath a large, orbicular, compressed root, from which arise a great number of angular heart-shaped leaves, upon

single foot-stalks, which are six or seven inches long; these leaves are marked with black in their middle; the flowers appear before the leaves, rising immediately from the root, with long fleshy foot-stalks; they appear in August and September, and soon after the leaves come out, continue growing all the winter and spring till May, when they begin to decay, and in June they are entirely dried up. After the flowers are fallen, the foot-stalks twist up like a screw, inclosing the germen in the center, and lay down close to the surface of the ground between the leaves, which serve as a protection to the seed. This germen becomes a round fleshy seed-vessel with one cell, inclosing several angular seeds. The seeds ripen in June, and should be sown in August. There are two varieties of this, one with a white and the other with a purplish flower, which appear at the same time.

The second sort flowers in autumn: this is at present very rare in England; the leaves of this sort are large, orbicular, and heart-shaped at their base, and of a purple colour on their under side; the leaves and flowers of this come up from the root at the same time; the flowers are of a purplish colour, and their bottoms are of a deep red. It flowers late in the autumn, and requires protection from the frost in winter.

The third sort hath stiff heart-shaped leaves which are sawed on their edges; these have strong fleshy foot-stalks near six inches long, of a purple colour, as are also the veins of the leaves on their under side, but the upper side is veined and marbled with white. The flowers rise with single foot-stalks from the root; these are pure white with a bright purple bottom; the petal is divided into nine segments to the bottom, which are twisted and reflexed backward like the other sorts. This flowers in March and April, and the seeds ripen in August.

The fourth sort is commonly called the Persian Cyclamen. This hath large, angular, heart-shaped leaves, whose edges are entire; they are veined and marbled with white on the upper side, and stand upon pretty long foot-stalks; the flowers are large, of a pale purple colour, with a bright red or purple bottom. These appear in March and April, and the seeds ripen in August.

The fifth sort hath a small irregular root not larger than a Nutmeg; the leaves are orbicular and small; the flowers are of a flesh colour, small, and have purple bottoms. They appear in the autumn, but rarely produce seeds in England.

The sixth sort is not so tender as the four last mentioned, so may be planted in warm borders, where, if they are covered in hard frost, they will thrive and flower very well. This hath plain orbicular leaves, which have shorter and weaker foot-stalks than either of the other; their under sides are very red in the beginning of winter, but that colour goes off in the spring; their upper sides are smooth, of a lucid green, and spread open flat; whereas the other sorts are hollowed, and reflexed at their base. The flowers are of a very bright purple colour, and appear in the middle of winter, at a time when there are few other flowers, which renders the plants more valuable. The seeds of this sort ripen in the end of June.

There are several other varieties of this plant, which chiefly differ in the colour of their flowers, particularly among the Persian kind, of which there is one with an entire white flower, which smells very sweet; but as these are accidental variations, I have not enumerated them here, those which are here mentioned being undoubtedly distinct species; for I have many years propagated them from seeds, and have not found them vary, nor have I heard that any other person has observed either of them alter farther than varying of their colours. Though Dr. Linnæus supposes them but one species, it is well known that the first sort will endure the greatest frost in the open air, whereas all the Persian sorts are tender, and require shelter in winter.

All the sorts are propagated by seeds, which should

be sown soon after they are ripe, in boxes or pots filled with light kitchen-garden earth, mixed with a little sand, and covered about half an inch deep, placing them where they may have only the morning sun till the beginning of September, when they may be removed to a warmer exposure. Those of the first sort may be plunged into the ground close to a south wall, a pale, or Reed hedge, in October, where, if it should be very severe frost, it will be proper to cover them either with mats or Pease-haulm, but in common winters they will not require any covering. The pots or tubs in which the Persian kinds are sown, should then be placed under a common hot-bed frame, where they may be protected from frost and hard rains, but in mild weather the glasses may be taken off every day to admit fresh air to them. The first sort will come up about Christmas, if the seeds were sown in August, and their leaves will continue green till May; and those of the Persian kinds will come up early in the spring, and continue green till June, when they will begin to decay; then they should be removed to an east aspect, where they will have only the morning sun, in which situation they may remain till the middle of August; during which time they should have very little water, for then the roots are in an inactive state, when much wet will rot them. The pots and tubs in which they are sown, must be constantly kept clean from weeds; for if the weeds are permitted to grow, their roots will closely entangle with those of the Cyclamen; so that in pulling out the weeds, the other roots will be drawn out with them. In the beginning of October, there should be some fresh earth spread over the tubs or pots, which should be removed again into shelter, in the same manner as before; and the following summer they must be managed also in the same way till their leaves decay, when they should be carefully taken up, and those of the first sort placed in a warm border at three or four inches distance, but the other sorts must be planted in pots to be sheltered in winter.

The third, fourth, and fifth sorts, are more impatient of cold and wet than the other three; these must constantly be preserved in pots filled with sandy light earth, and housed in winter, but should be placed near the glasses, where they may enjoy as much free open air as possible, when the weather will permit; for if they are crowded under other plants, and are kept too close, they are very subject to mould and rot; nor should they have much water in winter, which is also very injurious to them, but whenever they want water, it should be given them sparingly. In summer these plants may be exposed to the open air, when their green leaves will decay; at which time you should remove them to a place, where they may have the morning sun until eleven o'clock; but during the time that the roots are destitute of leaves, they should have very little water given them, because at that season they are not capable of discharging the moisture. This is also the proper season to transplant the roots, or to fresh earth them; and as the autumn comes on, that the heat decreases, they may be removed into places more exposed to the sun, where they may remain until October before they need be housed.

Toward Christmas, if the roots are in good health, the sixth sort will begin to flower, and continue producing fresh flowers till the middle of February, and these will be succeeded by the Persian sorts, which continue till May; but if you intend to have any seeds, you must let the pots be placed so as to receive a great share of fresh air, for if their flowers are drawn up in the house, they seldom produce any seeds. These seeds are ripe about July, when they should be immediately sown in pots or cases of good light undunged earth, which should be sheltered in winter under a frame, and exposed in summer in the same manner as is directed for the older roots, observing to remove them into pots at a wider distance when they are two years old; and so from time to time, as their roots increase in bulk, you must give them more

room;

C Y D

room; and in about four or five years time they will begin to flower, when you should let each root have a separate pot, which at first may be small, but when the roots are grown large, they must be put into larger pots.

These sorts have been planted under warm walls in the full ground, where, in mild winters they have done very well, but in severe frost all those roots have been destroyed; therefore, whenever these roots are planted in an open border, there should be common hot-bed frames placed over them in winter, that in bad weather they may be covered to protect them from frost: and where they are thus managed, the plants will produce more flowers, which will be much fairer than what are produced from the roots in the pots, and from these there may always be good seeds expected: therefore such persons who are curious in flowers, should have a border framed over on purpose for these, the Guernsey and Belladonna Lilies, with some other of the curious bulbous-rooted flowers; in which border there may be many of these curious flowers cultivated, to more advantage than in any other method now practised.

CYDONIA. Tourn. Inst. R. H. 632. tab. 405. Pyrus. L in. Gen. Plant. 550. [so called from Cydon, a town of Crete, famous for this fruit.] The Quince-tree.

The CHARACTERS are,

The flower is composed of five large, roundish, concave petals, which are inserted in the permanent empalement of one leaf. The germen is situated under the flower, and supports five slender styles, crowned by single stigmas; these are attended by near twenty stamina, which are inserted in the empalement, but are not so long as the petals; the germen afterward becomes a pyramidal or roundish fruit, which is fleshy, and divided into five cells, in which are lodged several hard kernels or seeds.

This genus of plants is ranged in the eighth section of Tournefort's twenty-first class, which includes the trees and shrubs with a Rose flower, whose empalement becomes a fruit pregnant with hard seeds. Dr. Linnæus has joined this genus, and also the Apple to the Pear, making them only species of the same genus, to which the Quince is nearly allied by its characters, which the Apple is not. However, though the joining of the Quince to the Pear may be allowed in a system of botany, yet in a book of gardening, it may not be quite so proper, therefore I have chosen to continue them under their former well known titles.

The SPECIES are,

1. **CYDONIA (Oblonga)** foliis oblongo-ovatis subtus tomentosis, pomis oblongis basi productis. *Quince-tree with oblong oval leaves, woolly on their under side, and an oblong fruit lengthened at the base.* Cydonia fructu oblongo læviori. Tourn. Inst. R. H. 632.
2. **CYDONIA (Maliforma)** foliis ovatis, subtus tomentosis, pomis rotundioribus. *Quince-tree with oval leaves, woolly on their under side, and a rounder fruit.* Cydonia fructu brevior & rotundior. Tourn. Inst. R. H. 633. Commonly called the *Apple Quince*.
3. **CYDONIA (Lusitanica)** foliis obversè-ovatis subtus tomentosis. *Quince-tree with obverse oval leaves, woolly on their under side.* Cydonia latifolia Lusitanica. Tourn. Inst. 633. *Broad-leaved Portugal Quince.*

There are some other varieties of this fruit which are propagated in fruit-gardens, and in the nurseries for sale, one of which is a soft eatable fruit; there is another with a very astringent fruit, and a third with a very small fruit, cottony all over, and is scarce worth keeping: these I suppose to be seminal variations, but the three sorts before enumerated, I take to be distinct species, having propagated them by seeds, and have not found them to vary.

The Portugal Quince is the most valuable, the pulp of it turning to a fine purple when stewed or baked, and becomes much softer and less austere than the others, so is much better for making of marmalade.

They are all easily propagated either by layers, suckers, or cuttings, which must be planted in a moist soil. Those raised from suckers are seldom so well

C Y N

rooted as those which are obtained from cuttings or layers, and are subject to produce suckers again in greater plenty, which is not so proper for fruit-bearing trees. The cuttings should be planted early in the autumn, and in very dry weather must be often watered to encourage their rooting. The second year after they should be removed into a nursery at three feet distance row from row, and one foot asunder in the rows, where they must be managed as was directed for Apples. In two or three years time these trees will be fit to transplant, where they are to remain for good, which should be either by the side of a ditch, river, or in some other moist place, where they will produce a greater plenty, and much larger fruit than in a dry soil; though those in a dry soil will be better tasted, and earlier ripe. These trees require very little pruning; the chief thing to be observed is, to keep their stems clear from suckers, and cut off such branches as cross each other; likewise all upright luxuriant shoots from the middle of the tree should be taken entirely out, that the head may not be too much crowded with wood, which is of ill consequence to all sorts of fruit-trees. These sorts may also be propagated by budding or grafting upon stocks raised by cuttings, so that the best sorts may be cultivated in greater plenty this way, than by any other method; and these trees will bear fruit much sooner, and be more fruitful than those which come from suckers or layers.

These are also in great esteem for stocks to graft and bud Pears on, which for summer and autumn fruits are a great improvement to them, especially those designed for walls and espaliers; for the trees upon these stocks do not shoot so vigorously as those upon free stocks, and therefore may be kept in less compass, and are sooner disposed to bear fruit: but hard winter fruits do not succeed so well upon these stocks, their fruit being very subject to crack, and are commonly stony, especially all the breaking Pears; therefore these stocks are only proper for the melting Pears, and for a moist soil. The best stocks are those which are raised from cuttings or layers.

As the Pear will take upon the Quince by grafting or budding, and so vice versa, we may conclude there is a near alliance between them; but as neither of these will take upon the Apple, nor that upon either of these, so we should separate them under different genera, as will be further mentioned under the article **MALUS**.

CYNANCHUM. Lin. Gen. Plant. 268. Apocynum. Tourn. Inst. R. H. 91. Periploca. Tourn. Inst. 93. tab. 22.

The CHARACTERS are,

The flower hath one petal; it hath scarce any tube, but is spread open, plain, and divided into five parts; this hath a small, erect, permanent empalement of one leaf, divided into five parts; the nectarium, which is situated in the center of the flower, is erect, cylindrical, and the length of the petal. It hath five stamina which are parallel to the nectarium, and of the same length, terminated by summits which reach to the mouth of the petal. It hath an oblong bifid germen, with scarce any style, crowned by two obtuse stigmas; the empalement becomes a capsule with two oblong pointed leaves, having a cell which opens longitudinally, and is filled with seeds lying over each other imbricately, and are crowned with long down.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. **CYNANCHUM (Acutum)** caule volubili herbaceo, foliis cordato-oblongis glabris. Hort. Cliff. 79. *Cynanchum with a twining herbaceous stalk, and oblong, smooth, heart-shaped leaves.* Periploca Monspeliaca foliis acutioribus. Tourn. Inst. 93. Commonly called *Montpelier Scammony*.
2. **CYNANCHUM (Monspeliacum)** caule volubili herbaceo, foliis reniformi-cordatis acutis. Hort. Cliff. 79. *Cynanchum with a twining herbaceous stalk, and kidney, heart-shaped, pointed leaves.* Periploca Monspeliaca foliis

foliis rotundioribus. Tourn. Inst. R. H. 93. *Round-leaved Montpellier Scammony.*

3. CYNANCHUM (*Suberosum*) caule volubili infernè iuberoso fisso, foliis cordatis acuminatis. Hort. Cliff. 79. *Cynanchum with a twining fungous stalk, having fissures on the under side, and heart-shaped pointed leaves.* Periploca Caroliniensis, flore minore stellato. Hort. Elth. 300.
4. CYNANCHUM (*Hirtum*) caule volubili fruticoso, infernè suberoso fisso, foliis ovato-cordatis. Hort. Cliff. 79. *Cynanchum with a shrubby twining stalk, whose lower part is fungous, having fissures, and oval heart-shaped leaves.* Periploca scandens, folio citri, fructu maximo. Plum. Cat. 2.
5. CYNANCHUM (*Erectum*) caule erecto divaricato, foliis cordatis glabris. Hort. Cliff. 79. *Cynanchum with an upright divaricated stalk, and heart-shaped smooth leaves.* Apocynum folio subrotundo. C. B. P. 302.
6. CYNANCHUM (*Asperum*) caule volubili fruticoso, foliis cordatis acutis asperis, floribus lateralibus. *Cynanchum with a twining shrubby stalk, heart-shaped, pointed, rough leaves, and flowers growing from the sides of the stalks.* Apocynum scandens foliis cordatis asperis, floribus amplis patulis luteis. Houst. MSS.

The first and second sorts grow naturally about Montpellier; these have perennial creeping roots, but annual stalks, which decay to the root every autumn, and rise afresh in the spring; these stalks twist themselves like Hops, round whatever plants are near them, and rise to the height of six or eight feet; the first of these is garnished with oblong, heart-shaped, smooth leaves, ending in acute points, and are placed by pairs opposite on long foot-stalks; the flowers come out in small bunches from the wings of the leaves; they are of a dirty white colour, and divided into five acute segments, which spread open in form of a star. These appear in June and July, but are not succeeded by any seed-vessels in England, which may be occasioned by their roots creeping so far under ground; for most of those plants which propagate themselves so much by their roots, become barren of seeds, especially if their roots have full liberty to extend.

The second sort differs from the first in the shape of its leaves, which are broader and rounder at their base. The roots of this sort are very thick, running deep into the ground, and extend themselves far on every side; so that where this plant hath got possession of the ground it is not easily extirpated, for every piece of the root will shoot, which may happen to be left in the ground. Both these plants abound with a milky juice like the Spurge, which issues out wherever they are broken; and this milky juice when concreted, has been frequently sold for scammony.

These plants propagate too fast by their creeping roots when they are admitted into gardens, so few people care to have them: the roots may be transplanted any time after their stalks decay, till they begin to shoot in the spring.

The third sort grows naturally in Carolina, from whence the seeds were brought to England; this is a perennial plant with twining hairy stalks, which, if supported, will rise six or seven feet high; the lower part of the stalks are covered with a thick fungous bark, somewhat like cork, which is full of fissures; these stalks are slender, and garnished at each joint with two oblong, heart-shaped, pointed leaves, standing on long hairy foot-stalks. The flowers are produced in small bunches at the wings of the leaves, these are star-shaped and green when they first appear, but afterward fade to a worn-out purple colour. They appear in July and August, but are not succeeded by seeds in England.

This plant will live in the open air in England, if it is planted in a dry soil and warm situation. It may be propagated by laying down some of the young shoots about Midsummer, which, if they are now and then refreshed with water, will put out roots, so may be transplanted in the autumn, where they are designed to remain. The roots of this plant should

be covered in winter with some rotten tan to keep out the frost, otherwise in severe winters they are liable to be destroyed.

The fourth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houstoun; this rises with a twining stalk to the height of twenty feet or upward, provided it hath support; the lower part of the stalks are covered with a thick fungous bark, full of fissures, which gape open; the leaves are oblong and smooth, and placed by pairs opposite, standing on long foot-stalks: the flowers are produced from the wings of the leaves in small bunches, they are star-shaped, and are of a yellowish green colour, but are not succeeded by pods in England.

This sort is tender, so will not thrive in this country unless it is placed in a warm stove, and requires the same treatment as other tender plants from the same country; and as it abounds with a milky juice, so the plants must have little water in winter. This may be propagated by laying down of the young shoots, which in three or four months will put out roots, and may then be transplanted into pots filled with light sandy earth, and plunged into the tan-bed in the bark-stove, where the plants should continue all the year.

The fifth sort grows naturally in Syria; this is a perennial plant, which rises with slender upright stalks about three feet high, garnished with broad, smooth, heart-shaped leaves ending in points, placed opposite; the flowers come out from the wings of the leaves in small bunches, standing on branching foot-stalks; these are small and white, greatly resembling those of the common white Asclepias, or Swallow-wort, and are succeeded by oblong taper pods, filled with flat seeds crowned with down, but these rarely ripen in this country.

It is propagated by parting of the root; the best time for doing of this or transplanting of the roots, is in the spring, before they shoot: this requires a warm situation, otherwise it will not live abroad in England.

The sixth sort grows naturally at La Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houstoun; this hath a shrubby twining stalk, which twists about whatever prop is near it, and rises to the height of twenty feet or upward; the stalks are very slender, and are armed with small stinging hairs, and garnished with broad heart-shaped leaves, which end in acute points; these are placed by pairs at each joint, which are far distant, and have slender foot-stalks; they are covered with rough hairs on their under side; the flowers are produced in small clusters, sitting close to the side of the stalks; they are pretty large, yellow, and star-shaped, spreading open to the bottom; they are succeeded by long swelling pods, filled with flat seeds lying imbricately, which are crowned with long down.

This sort is tender, so requires the same treatment as the fourth, and is propagated the same way.

CYNARA. Lin. Gen. Plant. 835. Cinara. Tourn. Inst. R. H. 442. tab. 254. Artichoke, in French *Artichaut*.

The CHARACTERS are,

It hath a compound flower, made up of many hermaphrodite florets, which are included in one common scaly empalement, which is swollen in the bottom. The florets are tubulous, equal, and uniform, divided at the top into five narrow segments. These have five short hairy stamina, terminated by cylindrical summits, which have five indentures; at the bottom of each is situated an oval germen, supporting an oblong style, crowned by an oblong indented stigma. The germen afterward becomes a single, oblong, compressed, four-cornered seed, crowned with long hairy down.

This genus of plants is ranged in the first section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia æqualis; the plants of this class and section have only hermaphrodite florets which are fruitful.

The SPECIES are,

1. CYNARA (*Scolymus*) foliis subspinosis, pinnatis indivisisque, calycinis squamis ovatis. Lin. Sp. Plant. 827. *Artichoke with spiny leaves which are winged and undivided, and an oval scaly empalement.* Cynara hortensis aculeata. C. B. P. 383. *The green or French Artichoke.*
2. CYNARA (*Hortensis*) foliis pinnatis inermibus, calycinis squamis obtusis emarginatis. *Artichoke with winged leaves having no spines, and obtuse indented scales to the empalement.* Cynara hortensis foliis non aculeatis. C. B. P. 383. *The Globe Artichoke.*
3. CYNARA (*Cardunculus*) foliis spinosis, omnibus pinnatifidis, calycinis squamis ovatis. Lin. Sp. Plant. 827. *Cynara with prickly leaves which all end in winged points, and oval scales to the empalement.* Cynara spinosa, cujus pediculi esitantur. C. B. P. 383. *The Cardoon, in French Chardon.*
4. CYNARA (*Humilis*) foliis spinosis, pinnatifidis, subtus tomentosis, calycibus squamis subulatis. Lin. Sp. Plant. 828. *Cynara with winged prickly leaves, woolly on their under side, and awl-shaped scales to the empalement.* Cynara sylvestris Boetica. Clus. Cur. Post. 15. *Wild Artichoke of Spain.*

The first sort is commonly known here by the title of French Artichoke, being the sort which is most commonly cultivated in France, and is the only kind in Guernsey and Jersey; the leaves of this sort are terminated by short spines, the head is oval, and the scales do not turn inward at the top like those of the Globe Artichoke, the heads are also of a green colour; the bottoms of these are not near so thick of flesh as those of the Globe, and they have a perfumed taste, which to many persons is very disagreeable; so that it is seldom cultivated in the gardens near London, where the Globe or red Artichoke is the only sort in esteem. The leaves of this are not prickly, the head is globular, a little compressed at the top, the scales lie close over each other, and their ends turn inward, so as to closely cover the middle.

The culture of these having been fully treated under the article ARTICHOKE, the reader is desired to turn to that, to avoid repetition.

The Chardon, or Cardoon, is propagated in the kitchen gardens to supply the markets; this is annually raised from seeds, which should be sown upon a bed of light earth in March; and when the plants come up, they should be thinned where they are too close; and if the plants are wanted, those which are drawn out may be transplanted into a bed at about three or four inches distance, where they should remain till they are transplanted out for good. These young plants must be kept clean from weeds, and in the beginning of June they must be transplanted out, on a moist rich spot of ground at about four feet asunder every way; the ground should be well dug before they are planted, and the plants should be well watered until they have taken new root, after which the ground must be kept very clean from weeds, to encourage the growth of the plants; and as they advance in height, there should be some earth drawn up about each plant; and when they are fully grown, their leaves should be closely tied up with a hay-band, and the earth drawn up in hills about each plant, almost to their tops, being careful to keep the earth from falling between the leaves, which may occasion the rotting of the plants. The earth should be smoothed over the surface that the wet may run off, and not fall into the center of the plants, which will also cause them to rot; in about eight or ten weeks after the plants have been thus earthed, they will be blanched enough for use; so that if a succession of them are wanted for the table, there should be but few plants earthed up at the same time; but once in a fortnight there may be a part of them earthed, in proportion to the quantity desired.

Toward the middle, or latter end of November, if the frost should be severe, it will be proper to cover the tops of those plants which remain with Pease-haulm or straw, to prevent the frost from penetrating

to the tender leaves, which frequently pinches them where there is not this covering, but this should be taken off again in mild weather; if this care is taken, the plants may be preserved for use most part of the winter.

If a few of the plants are planted out in a warm situation to stand for seed, they should not be blanched, but only in very hard frost some light litter, or Pease-haulm, may be laid round them to keep out frost, which should be removed in the spring, and the ground gently dug between the plants, which will not only destroy the weeds, but also encourage the roots of the plants to shoot out on every side, whereby their stems will be stronger; these will flower about the beginning of July, and if the season proves dry, their seeds will ripen in September; but in cold wet seasons, these seeds will not come to maturity in England.

The fourth sort grows naturally in Spain, and also on the African shore, and is preserved in gardens for the sake of variety; this is very like the third sort, but the stems of the leaves are much smaller, and do not grow more than half so high. The heads of this have some resemblance to those of the French Artichoke, but have no meat, or fleshy substance in their bottoms: this may be planted in the same manner as the third sort, at about three or four feet apart, and will require no other treatment, than the keeping them clean from weeds; the second year they will flower, and, if the season proves dry, they will ripen their seeds in September, and the plants generally decay the following winter, especially if the winter proves severe, unless they are covered.

CYNOGLOSSUM. Lin. Gen. Plant. 168. Tourn. Inst. R. H. 139. tab. 57. Omphalodes. Tourn. 140. tab. 59. [Κυνόγλωσσον, of Κυνός, a dog, and Γλῶσσα, Gr. the tongue, so called because the leaves of this plant resemble a dog's tongue.] Hounds Tongue, in French, *Langue de Chien*.

The CHARACTERS are,

It hath a funnel-shaped flower of one leaf, with a long tube, and a short brim, which is slightly cut into five parts, and is shut up at the chaps; this hath an oblong permanent empalement, cut into five acute segments. The flower hath five short stamina in the chaps of the petal, terminated by roundish summits, and at the bottom of the tube are situated four germen, between which arises a permanent style the length of the stamina, crowned by an indented stigma; the empalement afterward becomes four capsules, inclosing four oval seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. CYNOGLOSSUM (*Officinale*) staminibus corollâ brevioribus, foliis lato-lanceolatis tomentosis sessilibus. Lin. Sp. Plant. 134. *Hounds Tongue with stamina shorter than the petal, and broad spear-shaped leaves, which are woolly, sitting close to the stalk.* Cynoglossum majus vulgare. C. B. P. 257. *Common greater Hounds Tongue.*
2. CYNOGLOSSUM (*Appeninum*) staminibus corollam æquantibus. Hort. Upsal. 33. *Hounds Tongue with stamina equalling the petal.* Cynoglossum montanum maximum. Tourn. Inst. R. H. 139.
3. CYNOGLOSSUM (*Creticum*) foliis oblongis tomentosis, amplexicaulibus, caule ramoso, spicis florum longissimis sparsis. *Hounds Tongue with oblong woolly leaves embracing the stalks, a branching stalk, and very long loose spikes to the flowers.* Cynoglossum Creticum latifolium foetidum. C. B. P. 257.
4. CYNOGLOSSUM (*Cheirifolium*) corollis calyce duplo longioribus, foliis lanceolatis. Prod. Leyd. 406. *Hounds Tongue having a petal twice the length of the empalement, and spear-shaped leaves.* Cynoglossum Creticum, argenteo angusto folio. C. B. P. 257.
5. CYNOGLOSSUM (*Virginianum*) foliis amplexicaulibus ovatis. Lin. Sp. 193. *Hounds Tongue with oval leaves which embrace the stalk.* Cynoglossum Virginianum flore minimo albo. Banister. Cat.

6. CYNOGLOSSUM (*Lusitanicum*) foliis linearis lanceolatis scabris. Lin. Sp. 193. *Hounds Tongue with linear, spear-shaped, rough leaves.* Omphalodes Lusitanica elatior Cynoglossi folio. Tourn. Inst. R. H. 140.
7. CYNOGLOSSUM (*Linifolium*) foliis linearis lanceolatis glabris. Hort. Cliff. 47. *Hounds Tongue with smooth, narrow, spear-shaped leaves.* Omphalodes Lusitanica lini folio. Tourn. Inst. 140. *Commonly called Venus Navelwort.*

8. CYNOGLOSSUM (*Omphalodes*) repens, foliis radicalibus cordatis. Hort. Cliff. 47. *Creeping Hounds Tongue, whose lower leaves are heart-shaped.* Omphalodes pumila verna symphyti folio. Tourn. Inst. 140.

The first sort grows naturally by the side of hedges and foot-ways in many parts of England, so is seldom admitted into gardens; the roots of this sort are used in medicine, which are gathered by the herb-folks in the fields. The leaves of this plant have a strong odour, like that of mice in a trap. It flowers in June, and the seeds ripen in autumn.

The second sort grows naturally on the Apennine mountains; the leaves of this sort are much larger, the petal of the flower is shorter, and the plants grow taller than those of the first, and come earlier to flower in the spring; this is equally hardy as the common sort, and where the seeds are permitted to scatter, there will be plenty of the plants arise without care.

The third sort grows naturally in Andalusia, I received the seeds of this from Gibraltar; this hath a tall branching stalk, garnished with oblong woolly leaves, which embrace the stalk with their base. The flowers are produced in loose spikes, which come out from the side of the stalk, and are from six to eight inches long, the flowers are thinly placed on one side; these are blue, striped with red, and appear in June. The seeds ripen in autumn, soon after which the root decays.

The fourth sort grows naturally in Spain, and also in the island of Crete; I received this from Gibraltar, with those of the former; this rises with an upright stalk little more than a foot high, garnished with long, narrow, silvery leaves, having no foot-stalks. The flowers are produced from the side, and at the top of the stalks, which are but thinly dispersed on the side, but at the top of the stalk are in small clusters; they are of a deep purple colour, and much longer than the empalement; these are succeeded by four broad buckler-shaped seeds, which are rough. It flowers in June, and the seeds ripen in autumn, soon after which the roots generally perish.

The fifth sort grows naturally in Virginia, and in other northern parts of America; this rises with an upright branching stalk near four feet high. The stalks and leaves are covered with rough hairs, the branches are spread out on every side, and are but thinly garnished with leaves, from three to near four inches in length, and little more than one inch broad in the middle, gradually lessening to both ends; they embrace the stalks with their base, and are placed alternate; the flowers grow scatteringly toward the end of the branches; these are small and white; they appear in June, and are succeeded by four small seeds, which ripen in autumn, and then the plants decay.

The sixth sort grows naturally in Portugal, where it was first distinguished from the seventh by Dr. Tournefort. The seventh sort had been long before that cultivated in the gardens for ornament, by the title of Venus Navelwort, but of late years that has been almost lost; and the sixth sort is now generally preserved in the English gardens; and the seeds are sold by the seedsmen under that title, and is a much larger plant than the other, so makes a better appearance. The leaves of the sixth sort are broad at their base, and are gradually narrowed to the end; they are slightly covered with hairs. The stalks grow nine or ten inches high, and divide into many branches, each being terminated by a long loose spike of white flowers, standing on separate foot-stalks, which are suc-

ceeded by four umbilicated seeds, from whence it had the title of Navelwort.

The seventh sort seldom rises more than five or six inches high; the stalks do not branch near so much as those of the sixth. The leaves are very narrow and long, of a grayish colour, and smooth. The flowers grow in short loose panicles at the end of the branches; these are white, but smaller than those of the other sort, and are succeeded by seeds of the same form. This plant was formerly titled Linum Umbilicatum, i. e. *umbilicated Flax*, from the leaves having some appearance of Flax, and the seeds having a hollow like a navel.

These are both annual plants, and have been commonly sown in gardens, with other low annual flowers, to adorn the borders of the flower-garden; but these should be sown in autumn, for those which are sown in the spring often fail, especially in dry seasons; and the autumnal plants always grow much larger than those which arise from the spring sowing, and come to flower earlier in the year. The seeds should be sown where the plants are designed to remain, for they do not bear transplanting, unless it is performed while they are young. The plants require no other culture but to be thinned where they are too close, and kept clean from weeds. They flower in June and July, and the autumnal plants come a month earlier; their seeds ripen in autumn.

The eighth sort is a low perennial plant, which grows naturally in the woods of Spain and Portugal, where it usually flowers about Christmas; this hath trailing branches, which put out roots from their joints, whereby it propagates very fast. The leaves are heart-shaped, of a bright green colour, and stand upon long slender foot-stalks. The flowers grow in loose panicles, which arise from the divisions of the stalk; they are shaped like those of Borage, but are smaller, and of a lively blue colour; they appear in March and April, and in a cool shady situation continue great part of May, but are rarely succeeded by seeds; but the plants propagate themselves so fast by their trailing branches, as to render the cultivation of them by seeds unnecessary. It delights in a moist cool situation.

CYPERUS, Cypress Grass.

There are about twenty species of this genus known, some of which grow naturally in England, but the far greatest number are natives of America, where they grow in moist squalid places; and as there are not above two or three species which are preserved in gardens, so it will be to little purpose to enumerate the others.

The SPECIES are,

1. CYPERUS (*Longus*) culmo triquetro folioso, umbella folioso supra decomposita, pedunculis nudis, spicis alternis. Prod. Leyd. 50. *Cypress with a three-cornered stalk, an umbel with many leaves, alternate spikes on naked foot-stalks. Long-rooted Cypress of the shops.*
2. CYPERUS (*Rotundus*) culmo triquetro subnudo, umbella decomposita, spicis alternis linearibus. Flor. Zeyl. 36. *Cypress with a three-cornered naked stalk, a decomposed umbel, and linear spikes placed alternate. Round-rooted Cypress of the shops.*

The first sort grows naturally in France and Italy, from whence the plant was brought for medicinal use, but at present it is very seldom used in England. The roots of this sort are composed of many strong fleshy fibres which root deep in the ground, sending up every spring a great number of grassy three-cornered leaves near two feet long; the flower-stalks are triangular, nearly of the same length, supporting an umbel at the top, having many narrow triangular leaves under it; the spikes of the umbel are like those of some sorts of grass, but the seeds rarely ripen in England; so the plant is here propagated by dividing the root in the spring, and if planted in a warm situation; will thrive here in the open air.

The second sort is tenderer than the first, so the round compressed roots should be planted in pots, and sheltered in winter.

CYPRIPEDIUM. Lin. Gen. Plant. 906. Calceolus. Tourn. Inst. R. H. 436. tab. 249. Ladies Slipper, in French, *Sabot*.

The CHARACTERS are,

It hath a simple spadix. The germen sits under the flower, which is covered with a spathe or sheath. The flowers have four or five narrow spear-shaped petals, which expand. The nectarium, which is situated between the petals, is swollen and hollow, in shape of a shoe, or slipper. It hath two short stamina which sit upon the pointal, and are terminated by erect summits, which join to the upper lip of the nectarium; below the flower is fixed a slender contorted germen, supporting a short style, adhering to the upper lip of the nectarium, crowned by an obsolete stigma. The germen afterward becomes an oval blunt capsule with three corners, having three furrows, three valves, and one cell, which is filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's twentieth class, intitled Gynandria Diandria, the plants of this class and section have two stamina fixed to the style.

The SPECIES are,

1. CYPRIPEDIUM (*Calceolus*) radicibus fibrosis, foliis ovato-lanceolatis caulinis. Act. Upsal. 1740. Ladies Slipper with fibrous roots, the leaves on the stalks oval and spear-shaped. Calceolus Mariæ. Ger. 359. Our Lady's Slipper.
2. CYPRIPEDIUM (*Bulbosum*) scapo unifloro, foliis oblongis glabris petalis angustis acuminatis. Ladies Slipper with one flower in a sheath, oblong smooth leaves, and very narrow pointed petals. Calceolus Mariæ luteus. Mor. H. R. Blofs. Yellow Ladies Slipper.
3. CYPRIPEDIUM (*Hirsutum*) foliis oblongo-ovatis venosis hirsutis, flore maximo. Ladies Slipper with oblong, oval, veined leaves, which are hairy, and a very large flower. Calceolus flore majore. Tourn. Inst. R. H. 437. Ladies Slipper with a larger flower.

The first sort grows naturally in some shady woods in the north of England. I found it in the park of Borough-Hall, in Lancashire, the seat of the late Robert Fenwick, Esq; It hath a root composed of many fleshy fibres, from which arise, in the spring, two, three, or more stalks, in proportion to the strength of the root; these grow nine or ten inches high, and are garnished with oval spear-shaped leaves, having a few longitudinal veins; in the bosom of one of the upper leaves is inclosed the flower-bud, which is supported by a slender foot-stalk, which generally turns a little bud on one side. The flower hath four dark purple petals, placed in form of a cross, which spread wide open. In the center is situated the large hollow nectarium, almost as large as a bird's egg, shaped like a wooden shoe, of a pale yellowish colour, with a few broken streaks; the opening is covered with two ears; the upper one is tender, white, and spotted with purple; the lower is thick, and of an herbaceous colour. The flowers appear about the end of May, and the stalks decay early in autumn.

The second sort grows naturally in Virginia, and other parts of North America; this hath longer and smoother leaves than the former. The two side petals of the flower are long, narrow, and terminate in acute points, and are wreathed, or undulated on their sides. The nectarium is oblong, and narrower than in the first sort, and is yellow, spotted with brownish red. The stalks rise near a foot and a half high.

The third sort grows naturally in America, where the inhabitants call it Moccasin Flower; this rises a foot and a half high. The leaves are of an oblong oval form, and are deeply veined. The flower is large, of a reddish brown colour, marked with a few purple veins. This sort flowers in the end of May.

All these sorts are with difficulty preserved in gardens; they must be planted in a loamy soil, and in a situation where they may have the morning sun only. They must be procured from the places where they naturally grow, for they cannot be propagated in gardens. The roots should be seldom removed, for transplanting them prevents their flowering.

CYSTICAPNOS. See FUMARIA.

CYTISO-GENISTA. See SPARTIUM.

CYTISUS. Lin. Gen. Plant. 785. Tourn. Inst. R. H. 647. tab. 416. [so called from Cythos, an island in the Archipelago, where it grew in great plenty.] Base-tree Trefoil, in French, *Citise*.

The CHARACTERS are,

It hath a butterfly flower, with a short bell-shaped empalement of one leaf, divided in two lips, the upper being bifid and acute, the under indented in three parts. The standard of the flower is rising, oval, and reflexed on the sides. The wings are obtuse, erect, and the length of the standard. The keel is bellied and acute. It hath ten stamina, nine joined, and one standing separate, terminated by rising summits. It hath an oblong germen, supporting a single style, crowned by an obtuse stigma. The germen afterward becomes an oblong blunt pod, narrow at their base, filled with kidney-shaped flattened seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, from the flowers having ten stamina divided into two bodies.

The SPECIES are,

1. CYTISUS (*Laburnum*) foliis oblongo-ovatis, racemis brevioribus pendulis, caule arboreo. Cytisus with oblong oval leaves, short spikes of flowers hanging downward, and a tree-like stalk. Cytisus Alpinus latifolius, flore racemoso pendulo. Tourn. Inst. R. H. 648. Commonly called Laburnum.
2. CYTISUS (*Alpinus*) foliis ovato-lanceolatis, racemis longioribus pendulis, caule fruticoso. Cytisus with oval spear-shaped leaves, long pendulous bunches of flowers, and a shrubby stalk. Cytisus Alpinus angustifolius, flore racemoso pendulo longiore. Tourn. Inst. R. H. 648. Commonly called long-spiked Laburnum.
3. CYTISUS (*Nigricans*) racemis simplicibus erectis, foliolis ovato-oblongis. Hort. Cliff. 354. Cytisus with single erect bunches of flowers, and oval oblong leaves. Cytisus glaber nigricans. C. B. P. 390. Black smooth Cytisus.
4. CYTISUS (*Sessilibus*) racemis erectis, calycibus bractea triplici auctis, foliis floralibus sessilibus. Lin. Sp. Plant. 739. Cytisus with erect bunches of flowers, three laminae under the empalement, and the leaves on the flower branches sitting close. Cytisus glabris, foliis subrotundis, pediculis brevissimis. C. B. P. 390. Commonly called by the gardeners, Cytisus secundus Clusii.
5. CYTISUS (*Hirsutis*) pedunculis simplicibus lateralibus, calycibus hirsutis trifidis ventricoso-oblongis. Hort. Upsal. 211. Cytisus with single foot-stalks on the side of the branches, trifid hairy empalements, oblong and bellied. Cytisus incanus siliqua longiore. C. B. P. 390. Commonly called hairy, or Evergreen Cytisus of Naples.
6. CYTISUS (*Argenteus*) floribus sessilibus, foliis tomentosis, caulibus herbaceis. Lin. Sp. Plant. 740. Cytisus with flowers sitting close to the branches, woolly leaves, and an herbaceous stalk. Cytisus humilis argenteus angustifolius. Tourn. Inst. 648.
7. CYTISUS (*Supinus*) floribus umbellatis terminalibus, ramis decumbentibus, foliolis ovatis. Lin. Sp. 1042. Low Cytisus with umbellated flowers terminating the branches, which are trailing, and oval leaves. Cytisus supinus foliis infra & siliquis molli lanugine pubescentibus. C. B. P. 390.
8. CYTISUS (*Austriacus*) floribus umbellatis terminalibus, caulibus erectis foliolis lanceolatis. Lin. Sp. 1042. Cytisus with umbellated flowers terminating the branches, erect stalks and spear-shaped leaves. Cytisus floribus capitatis, foliolis ovato-oblongis, caule fruticoso. Dict. Hort. Commonly called Siberian Cytisus.
9. CYTISUS (*Æthiopicus*) racemis lateralibus strictis, ramis angulatis, foliolis cuneiformibus. Lin. Sp. 1042. Cytisus with narrow bunches of flowers proceeding from the side of the branches, which are angular, and wedge-shaped leaves. Cytisus Æthiopicus, subrotundis incanis minoribus foliis, floribus parvis luteis. Pluk. Alm. 128.
10. CYTISUS (*Græcus*) foliis simplicibus lanceolato-linearibus, ramis angulatis. Lin. Sp. 1043. Cytisus with single, linear, spear-shaped leaves, and angular branches. Barba Jovis linariæ folio, flore luteo parvo. Tourn. Cor. 44.

11. *Cytisus* (*Cayan*) racemis axillaribus erectis, foliis sublancoatis tomentosis, intermedio longius petiolato. Flor. Zeyl. 357. *Cytisus* with erect spikes of flowers proceeding from the sides of the branches, and spear-shaped leaves which are woolly, the foot-stalk of the middle one being the longest. *Cytisus arborescens*, fructu eduli albo. Plum. Cat. 19. Commonly called Pidgeon Pea in America.

The first sort is the common broad-leaved Laburnum, which was formerly in greater plenty in the English gardens than at present; for since the second sort hath been introduced, it has almost turned this out; the spikes of flowers being much longer, they make a finer appearance when they are in flower, which has occasioned their being more generally cultivated; but the first grows to be the largest tree, and the wood of it is very hard, of a fine colour, and will polish very well; it approaches near to green Ebony, so is by the French titled Ebony of the Alps, and is there used for many kinds of furniture; but in England there are few of these trees which have been suffered to stand long enough to arrive to any considerable size, for as they have been only considered as an ornamental tree, the frequent alterations which most of the gardens in England have undergone, have occasioned their being rooted out wherever they were growing; but in some of the old gardens in Scotland, where they have been permitted to stand, there are large trees of this kind, which are fit to cut down for the use of the timber. I have seen two old trees of it in gardens, which were more than a yard in girth, at six feet from the ground, and these had been broken and abused, otherwise might have been much larger: they grow very fast, and are extremely hardy, so may be well worth propagating upon poor shallow soils, and in exposed situations. His Grace the Duke of Queensberry sowed a great quantity of the seeds of this tree, upon the side of the downs, at his seat near Amesbury, in Wiltshire, where the situation was very much exposed, and the soil so shallow, as that few trees would grow there; yet in this place the young trees were twelve feet high in four years growth, so became a shelter to the other plantations, for which purpose they were designed; but the hares and rabbits are great enemies to these trees, by barking them in winter, so that where these trees are cultivated, they should be fenced from these animals.

Both these sorts are easily propagated by seeds, which the trees produce in great plenty. If these are sown upon a common bed in March, the plants will appear by the middle or end of April, and will require no other care but to be kept clean from weeds during the following summer; and if the plants are too close together, they may be transplanted the autumn following, either into a nursery, where they may grow a year or two to get strength, or into the places where they are designed to remain: where people would cultivate them for their wood, it will be the best way to sow the seeds upon the spot where they are intended to grow, because these trees send out long, thick, fleshy roots to a great distance, which will penetrate gravel or rocks; and if these roots are cut or broken, it greatly retards their growth; therefore when they are not sown upon the intended spot, they should be transplanted thither young, otherwise they will not grow to near the size; though where they are only designed for ornament, the removing the plants twice will stop their growth, and cause them to be more productive of flowers; but all trees intended for timber, are much better sown on the ground where they are designed to stand, than if they are transplanted.

If the seeds of these trees are permitted to scatter in winter, the plants will rise in great plenty the following spring, so that a few trees will soon supply any person with a sufficient number of the plants.

These trees flower in May, at which time they make a fine appearance, their branches being generally loaded with long strings of yellow flowers, which hang down from every part. The seeds grow in long pods, which ripen in autumn. There is a variety of

both these trees with variegated leaves, which some persons are fond of cultivating; but this is only to be done by cuttings or layers, for the seeds of these will produce plants with green leaves: the cuttings should be planted in autumn, when the leaves begin to fall, and the plants must have a poor soil, for in good ground they are apt to become plain.

If the first sort comes to be considered as a useful wood, which there is no reason to doubt it may be, it may be planted in large clumps in parks, where they will be very ornamental; and I am certain, from long experience, that this tree will thrive upon many soils, and in such situations as few other trees will make any progress; the objection to fencing is the same here, as for any other trees, for wherever plantations are made, if they are not well secured from animals, they will not answer the design of the planters.

The second sort differs from the first, in having narrower leaves, longer bunches of flowers, and the trees do not grow so large and strong; this difference I find is constant from seed. There is another sort mentioned by Tournefort, with shorter bunches of flowers than either of these, one tree of which kind I thought I had found in a garden; the bunches of the flowers upon this tree were close and almost round, but I sowed the seeds of it, and the plants proved to be only the common sort.

The third sort grows naturally in Austria, in Italy and Spain, and at present is pretty rare in the English gardens; it was formerly in some of the curious gardens here, but had been long lost, till a few years ago, when I procured the seeds from abroad, which succeeded in the Chelsea gardens, where the plants have flowered and produced ripe seeds, which have been communicated to several curious persons.

This shrub seldom rises more than three or four feet high in England; it naturally puts out many lateral branches near the ground, which spread out on every side, so as to form a low shrubby bush, so is with difficulty raised to a stem: the branches are very slender, and their ends are frequently killed if the winter is severe; these are garnished with oblong oval leaves, growing by threes on each foot-stalk; they are equal in size, and of a dark green colour; the branches grow erect, and are terminated by spikes of yellow flowers, about four or five inches in length, standing upright; and as all the branches are thus terminated, so when the shrubs are in flower, they make a fine appearance; it flowers in July, after most of the other sorts are past, and the seeds ripen in autumn. This is propagated by seeds, which should be sown upon a bed of light earth in March, covering them about one third of an inch with fine screened mould; in the beginning of May the plants will appear, when they must be carefully weeded, and during the following summer they must constantly be kept clean, which is all the culture they require till autumn, when it will be very proper to arch the bed over with hoops, that in frosty weather the plants may be covered with mats, to prevent their tender shoots from being killed; for as these young plants are apt to continue growing later in the autumn than those which are become woody, so they are much more susceptible of cold; therefore where there is not some care taken to cover them, if the winter should prove severe, many of them may be entirely destroyed, and the others killed to the ground. The spring following, after the danger of hard frost is over, the plants should be carefully taken up, and planted out at the distance of one foot, row from row, and six inches asunder in the rows; this should be in a sheltered situation, and as these plants do not shoot till late in the spring, so they need not be transplanted before the end of March, or the beginning of April; and if the season should then prove warm and dry, it will be proper to give the plants some water to settle the earth to their roots; and if the drought continue, and the waterings are three times repeated at a week's interval from each, it will be of service to the plants. After they have taken new root, they will require

no farther care, but to keep them constantly clean from weeds; in this nursery the plants may remain two years, in which time they will have acquired strength enough to be transplanted where they are to remain. There is a figure of this shrub exhibited in the 117th plate of my figures of plants.

The fourth sort grows naturally in the south of France, in Spain and Italy, but has been long cultivated in the nursery gardens; as an ornamental flowering shrub, by the title of *Cytisus secundus* Clusii. This rises with a woody stalk, putting out many branches which are covered with a brownish bark, and garnished by obverse, oval, small leaves, growing by threes on very short foot-stalks. The flowers are produced in close short spikes at the end of the branches, standing erect; they are of a bright yellow colour, and appear in June; these are succeeded by short broad pods, which contain one row of kidney-shaped seeds, which ripen in August. These shrubs will rise to the height of seven or eight feet, and become very bushy; they are very hardy, so will thrive in any situation; and upon almost any soil, which is not too wet. They are propagated by seeds, which may be sown upon a common bed of light earth in the spring, and kept clean from weeds the following summer; and in autumn the plants may be transplanted into a nursery in rows, one foot apart, and at six inches distance in the rows, where they may remain two years to acquire strength, and should then be removed to the places where they are designed to grow.

The fifth sort hath a soft shrubby stalk, dividing into many branches, which grow erect, and frequently rise to the height of eight or ten feet; the stalks and leaves of this are very hairy; the leaves are oval, growing three upon each foot-stalk, and are placed closely on the branches; the flowers come out from the side of the stalk, in short bunches; they are of a pale yellow, and appear in June; these are succeeded by long, narrow, hairy pods, with one row of kidney-shaped seeds, which ripen in September.

This sort, of late years, has been much cultivated in the nursery gardens near London, by the title of Evergreen *Cytisus* of Naples; but as in severe frost these shrubs are sometimes killed, so they are not proper for every situation, therefore should only be planted on a dry soil, and in warm situations; they are also very difficult to remove, when grown to any size, for they shoot long roots deep into the ground, and when these are broken or cut, the plants seldom survive it. This may be propagated in the same manner as hath been directed for the third sort. It grows naturally in the south of France, in Spain and Italy. The sixth sort hath herbaceous stalks, garnished with woolly leaves; the flowers are produced sometimes single, at other times two, three, or more grow together at the end of the branches; these appear in June, and are succeeded by hairy pods.

This plant is propagated by seeds, which may be sown at the same time, and the plants should be afterward treated in the same way, as is directed for the third sort.

The seventh sort grows naturally in Sicily, Italy, and Spain; this is a perennial plant, from whose down-right root proceed several weak branches which trail upon the ground, and extend to the length of eight or ten inches; these are garnished with oblong leaves, placed by threes upon pretty long foot-stalks; they are hoary on their under side, but smooth above; the flowers are collected in heads at the end of the stalks, having a cluster of leaves under them; they are of a deep yellow colour, and appear the latter end of June, and in warm seasons these are succeeded by flat woolly pods, containing one row of small kidney-shaped seeds, which ripen in September. This plant is propagated by seeds, which should be sown where the plants are to remain, and should be treated in the same manner as the sixth sort.

The eighth sort grows naturally in Tartary, from whence the seeds were sent to the Imperial garden at Peterburgh, and hath since been sent to many of the curious gardens in Europe, which have been fur-

nished with the seeds. This hath a shrubby stalk; which rises near four feet high, dividing into many branches, which when young are covered with a green bark, closely garnished by oblong, oval, smooth leaves, which are of a hoary green colour; the flowers are produced in close heads at the end of the branches, having a cluster of leaves under them; they are of a bright yellow colour, and appear in the beginning of May; these are sometimes succeeded by short woolly pods, containing three or four small kidney-shaped seeds in each. This is propagated by seeds, which should be sown early in April, on a border of strong ground exposed to the east; for if they are sown where they have full sun, the plants will not thrive. This requires a cold situation and a pretty strong soil, otherwise it will not thrive.

The ninth sort grows naturally about Algiers, from whence the Rev. Dr. Shaw brought the seeds, which succeeded in the Chelsea garden. This rises with a soft shrubby stalk to the height of eight or ten feet, putting out many slender branches on every side, garnished with small wedge-shaped leaves, which are indented at the top, of a dark green colour and smooth; the flowers come out frequently single from the side of the branches, these are large and of a bright yellow; they appear in June, and are sometimes succeeded by pods containing three or four kidney-shaped seeds, which ripen in autumn. This sort is too tender to live in the open air through the winter in England, therefore the plants must be treated in the same way as those which are natives of the same country.

The tenth sort grows naturally in the islands of the Archipelago; it rises with a ligneous stalk six or seven feet high, sending out many angular lateral branches, garnished with single, narrow, spear-shaped leaves; the flowers are produced in short bunches from the side of the branches; they are small, yellow, and appear in July and August, but are not succeeded by seeds in England.

This is propagated by cuttings, which if planted on a bed of light earth the beginning of July, and are closely covered with a bell or hand-glass, which should be shaded from the sun in the middle of the day, they will put out roots by the middle or end of September; when they should be carefully taken up, planting each in a separate small pot, carefully watering and shading them until they have taken new root; after which they may be exposed in a sheltered situation till the end of October, when they must be removed into shelter, for this plant is too tender to live in the open air in England.

The eleventh sort grows naturally in the islands of America, and also at the Cape of Good Hope. This rises with a weak shrubby stalk eight or ten feet high, sending out many erect side branches, which grow erect, and are garnished with spear-shaped woolly leaves, placed by threes, the middle lobe having a longer distinct foot-stalk, than the two on each side which grow close to the principal foot-stalk. The flowers come out from the side of the branches, sometimes single, at other times in clusters; they are of a deep yellow colour, and about the size of those of the common Laburnum; these are succeeded by hairy pods about three inches long, which are sickle-shaped, ending with a long acute point, swelling at the place where each seed is lodged; the seeds are roundish, a little inclined to a kidney-shape. These seeds are esteemed an excellent food for pigeons in America, from whence it had the title of Pigeon Pea.

This plant grows only in very warm countries, so cannot be preserved in England, unless it is placed in a warm stove. It rises easily from seeds in a hot-bed, and will grow three or four feet high the first year, provided they have a proper heat, and the second year they will produce flowers and seeds. The plants must be placed in the bark-bed in the stove, and treated in the same manner as other tender plants from the same countries: they should have but little water in winter, and in the summer should have a large share of free air admitted to them in warm weather.

D AFFODIL. See NARCISSUS.
D AISIES. See BELLIS.
D ALECHAMPIA. Lin. Gen. Plant.
 1022. Plum. Nov. Gen. 17. tab. 38.

This plant was so named by father Plumier, in honour of the memory of Jacobus Dalechamp, who was a curious botanist.

The CHARACTERS are,

It hath male and female flowers on the same plant; the male flowers are situated between two bractea; they have a common involucre cut into four erect segments; the empalement is composed of six obtuse oval leaves, reflexed at their points. They have no petals, but have a broad nectarium, having many plain folds lying over each other, and many stamina joined in a long column, terminated by roundish summits having four furrows; the female flowers are also situated in the same manner as the male; these have a permanent three-leaved involucre, and each have a permanent ten-leaved empalement; they have no petals, but a roundish germen shorter than the empalement, having three furrows supporting a long slender style, bending toward the male flowers, crowned by a beaded stigma; the germen afterward becomes a roundish capsule with three cells, inclosing one roundish seed in each.

This genus of plants is ranged in the ninth section of Linnæus's twenty-first class, intitled Monœcia Monadelphia, the plants having male and female flowers on the same root, and the stamina of the male flowers are joined in one body to the style.

We have but one SPECIES of this in England, viz.

DALECHAMPIA (*Scandens*) foliis trilobis glabris, floribus axillaribus caule volubili. *Dalechampia with smooth leaves having three lobes, flowers growing from the sides of the branches, and a twining stalk.* Dalechampia scandens, lupuli foliis, fructu tricocco glabro, calyce hispido. Houst. MSS.

This plant grows naturally in Jamaica, from whence the late Dr. Houstoun sent me the seeds, which succeeded in the Chelsea garden, where the plants have flowered and perfected their seeds. This must be a different plant from that which Plumier found growing in Martinico, or he has taken the involucre for the seed-vessel by his title of it; for he calls it fructu tricocco hispido, whereas this hath a smooth fruit with a hispid empalement.

It hath a root composed of many fibres, which extend to a great distance, from which arise several weak twining stalks, that fasten themselves to the neighbouring plants, and mount up to a considerable height; these are garnished at each joint by one leaf, having three lobes; they are smooth, the two side lobes are oblique to the midrib, but the middle one is equal. The flowers are produced from the side of the stalks, three or four growing upon each foot-stalk; some of these are male, and others female; they are of an herbaceous colour, and small, so make no appearance; they have each a double involucre, made up of two orders of leaves, which are narrow, and armed with small bristly hairs, which sting the hands of those who unwarily touch them; the flowers are succeeded by roundish capsules, having three prominent lobes which are smooth, each inclosing a single seed.

This plant is propagated by seeds, which must be sown early in the spring on a hot-bed; and when the

D A M

plants are come up three inches high, they should be carefully transplanted, each into a separate small pot, filled with light rich earth, and then plunged into a hot-bed of tanners bark, being careful to screen them from the sun until they have taken new root; after which time the glasses of the hot-bed should be raised every day, in proportion to the heat of the weather, to admit fresh air to the plants; they must also be frequently watered, for they naturally grow in moist places. When the plants have grown so large as to fill these pots with their roots, they should be removed into larger pots, and placed in the bark-bed in the stove, where they must be supported either with stakes or a trellis, round which they will twine, and rise to the height of eight or ten feet. These plants must be kept constantly in the stove, for they are too tender to bear the open air in this country, even in the summer season; therefore they should be placed with Convolvuluses, and other twining plants, near the back of the stove, where should be made an espalier to support them; in which situation they will thrive, and produce their flowers, and sometimes will perfect their seeds in this country; but, in order to this, they should have a large share of fresh air in warm weather, by drawing down the upper glasses of the stove; but in winter the stove should be kept to a temperate heat, or rather higher. In summer they will require a large share of water, but in winter it should be given to them in less quantities, but must be frequently repeated. These plants do not continue above two years, so that young plants should be raised in order to preserve the kind.

DAMASONIUM, Star-headed Water Plantain.

The CHARACTERS are,

It hath a flower composed of three leaves, which are placed orbicularly, and expand in form of a Rose: out of the flower-cup rises the pointal, which afterward becomes a star-shaped fruit, with many cells, which are full of oblong seeds.

The SPECIES are,

1. **D**AMASONIUM (*Alisma*) stellatum. Lugd. *Star-headed Water Plantain.*

2. **D**AMASONIUM (*Flava*) Americanum maximum, plantaginis folio, flore flavescente, fructu globoso. Plum. *Greatest American Water Plantain, with a Plantain leaf, a yellowish flower, and a globular fruit.*

The first of these plants is a native of England; it grows commonly in standing waters, which are not very deep. It is sometimes used in medicine, but never cultivated in gardens, so must be gathered for use in the places of its growth.

The second sort grows in Jamaica, Barbadoes, and several other places in the warm parts of America, where it is generally found in stagnating waters, and other swampy places; so that it would be difficult to preserve this plant in England, for it will not live in the open air, and requires a bog to make it thrive; but as it is a plant of no great beauty or use, it is not worth the trouble of cultivating in this country.

DANDELION. See LEONTODON.

DAPHNE. Lin. Gen. Plant. 436. Thymelæa. Tourn. Inst. R. H. 594. tab. 366. Spurge Laurel, or Mezereon.

The

The CHARACTERS are,

The flower hath no empalement; it is cylindrical, of one petal, which is cut into four parts at the top, where it spreads open; it hath eight short stamina inserted in the tube, which are alternately lower, terminated by erect bilocular summits. The oval germen is situated at the bottom of the tube, and is crowned by a beaded depressed stigma; the germen afterward becomes a roundish berry with one cell, inclosing one roundish fleshy seed.

This genus of plants is ranged in the first section of Linnæus's eighth class, intitled Octandria Monogynia, from the flower having eight stamina and one germen.

The SPECIES are,

1. DAPHNE (*Laureola*) racemis axillaribus, foliis lanceolatis glabris. Lin. Sp. Plant. 357. *Daphne with bunches of flowers proceeding from the sides of the branches, and smooth spear-shaped leaves. Thymelæa lauri folio sempervirens, seu laureola mas. Tourn. Inst. 595. Commonly called Spurge Laurel.*
2. DAPHNE (*Mezereon*) floribus sessilibus ternis caulinis, foliis lanceolatis deciduis. Lin. Sp. Plant. 357. *Daphne with three flowers together sitting close to the stalk, and spear-shaped leaves, which fall off in autumn. Thymelæa lauri folio deciduo, five laureola fœmina. Tourn. Inst. 595. Commonly called Mezereon.*
3. DAPHNE (*Thymelæa*) floribus sessilibus axillaribus, foliis lanceolatis, caulibus simplicissimis. Lin. Sp. Plant. 356. *Daphne with flowers sitting close to the sides of the branches, spear-shaped leaves, and single stalks. Thymelæa foliis polygalæ glabris. C. B. P. 463.*
4. DAPHNE (*Tarton-raire*) floribus sessilibus aggregatis axillaribus, foliis ovatis utrinque pubescentibus nervosis. Lin. Sp. Plant. 356. *Daphne with flowers in clusters sitting close to the sides of the branches, and oval nervous leaves covered with silky hairs on both sides. Thymelæa foliis candicantibus serici instar mollibus. C. B. P. 463. Commonly called Tarton-raire.*
5. DAPHNE (*Alpina*) floribus sessilibus aggregatis lateralibus, foliis lanceolatis obtusiusculis subtus tomentosis. Lin. Sp. Plant. 356. *Daphne with clusters of flowers growing close to the sides of the branches, and spear-shaped blunt leaves woolly on their under side. Chamaelæa Alpina, folio inferne incano. C. B. P. 462.*
6. DAPHNE (*Cneorum*) floribus congestis terminalibus sessilibus, foliis lanceolatis nudis. Lin. Sp. Plant. 357. *Daphne with clusters of flowers sitting close on the tops of the branches, and naked spear-shaped leaves. Cneorum. Matth. Hist. 46.*
7. DAPHNE (*Gnidium*) paniculâ terminali, foliis linearilanceolatis acuminatis. Lin. Sp. Plant. 357. *Daphne with a panicle of flowers terminating the branches, and narrow, spear-shaped, pointed leaves. Thymelæa foliis lini. C. B. P. 463.*
8. DAPHNE (*Squarrosa*) floribus terminalibus pedunculatis, foliis sparsis linearibus patentibus mucronatis. Lin. Sp. Plant. 358. *Daphne with flowers terminating the branches, having foot-stalks, and narrow, spreading, acute-pointed leaves, placed scatteringly on the branches. Thymelæa capitata lanuginosa, foliis creberrimis minimis aculeatis. Burm. Afr. 134. tab. 49. fol 1.*
9. DAPHNE (*Americana*) foliis linearibus acutis, floribus racemosis axillaribus. *Daphne with very narrow acute leaves, and flowers growing in bunches from the sides of the branches. Thymelæa frutescens rorismarini folio, flore albo. Plum. Cat.*

The first sort grows common in the woods in many parts of England, and is commonly known by the title of Spurge Laurel; of late years there are poor people, who get the young plants out of the woods, and carry them about the town to sell in the winter and spring. This is a low evergreen shrub, which rises with several stalks from the root to the height of two or three feet, dividing upward into several branches, garnished with thick spear-shaped leaves, which come out irregularly on every side, sitting pretty close to the branches, they are smooth and of a lucid green; between these, toward the upper part of the stalks, come out the flowers in small clusters; they are of a yellowish green, and appear soon

after Christmas, if the season is not very severe; these are succeeded by oval berries, which are green till June, when they ripen and turn black, soon after which they fall off. The whole plant is of a hot caustic taste, burning and inflaming the mouth and throat. The leaves continue green all the year, so these plants are ornamental in winter; and as they will thrive under tall trees, they are very proper to fill up the spaces in plantations.

The second sort grows naturally in Germany, and there hath been a discovery made of its growing in some woods near Andover in Hampshire, from whence a great number of plants have been taken of late years. This has been long cultivated in the nursery-gardens as a flowering shrub, and is a very ornamental plant in gardens, very early in the spring, before others make their appearance. There are two distinct sorts of this, one with a white flower which is succeeded by yellow berries, the other with Peach-coloured flowers and red fruit. These are by some supposed to be accidental varieties arising from the same seeds, but I have several times raised these plants from seeds, and always found the plants come up the same, as those from which the seeds were taken, so they do not vary, therefore may be called different species. There is a variety of the Peach-coloured Mezereon, with flowers of a much deeper colour than the common, but these I have always found to vary in their colours when raised from seeds. This shrub grows to the height of five or six feet, with a strong woody stalk, putting out many woody branches on every side, so as to form a regular head; the flowers come out very early in the spring, before the leaves appear, growing in clusters all round the shoots of the former year; there are commonly three flowers produced from each knot or joint, standing on the same short foot-stalk; these have short swelling tubes, which are divided into four parts at the top, which spread open; they have a very fragrant odour, so that where there are plenty of the shrubs growing together, they perfume the air to a considerable distance round them: after the flowers are past, the leaves come out, which are smooth, spear-shaped, and placed without order; they are about two inches long, and three quarters broad in the middle, gradually lessening to both ends; the flowers are succeeded by oval berries, which ripen in June; those of the Peach-coloured flowers are red, and those of the white yellow. The flowers appear in February and March, and sometimes in mild winters they appear in January. This plant was formerly used in medicine, but as every part of it has a hot caustic taste, so few prescribe the use of it at present.

This is propagated by seeds, which should be sown on a border exposed to the east, soon after the berries are ripe; for if they are not sown till the spring following they often miscarry, and always remain a year in the ground before the plants appear; whereas those which are sown in August, will grow the following spring, so that a year is saved, and these never fail. When the plants come up, they will require no other care but to keep them clean from weeds, and if the plants are not too close together, they may continue in the seed-bed, to have the growth of two summers, especially if they do not make great progress the first year; then at Michaelmas, when the leaves are shedding, they should be carefully taken up so as not to break or tear their roots, and planted into a nursery at about sixteen inches row from row, and eight or nine inches asunder in the rows; in this nursery they may remain two years, by which time they will be fit to remove to the places where they are designed to remain for good: the best season to transplant these trees is in autumn, for as these plants begin to vegetate very early in the spring, so it is not proper to transplant them at that season. These plants grow best in a light sandy earth which is dry, for in cold wet land they become mossy, and make little progress; so that upon such soils they never grow to any size, and produce few flowers.

Although

Although the berries of this tree are so very acrid, as to burn the mouth and throat of those who may incautiously taste them, yet the birds greedily devour them, as soon as they begin to ripen; so that unless the shrubs are covered with nets to preserve the berries, they will all be destroyed before they are fit to gather. There is of this and the former sort, some plants with variegated leaves, which some persons are fond to have in their gardens, but the plain are much more beautiful.

The third sort grows naturally in Spain, Italy, and the south of France, where it rises to the height of three or four feet, with a single stalk covered with a light-coloured bark; the flowers come out in clusters on the sides of the stalks, which are of an herbaceous colour, so make but little appearance; they appear early in the spring, and are succeeded by small berries which are yellowish when ripe.

The fourth sort grows naturally in the south of France, from whence I received the seeds. This is a low shrubby plant, which sends out several weak stalks from the root, which grow about a foot long, and spread about irregularly; these seldom become woody in England, but are tough and stringy, covered with a light bark; the leaves are small, of an oval form, and are very soft, white, and shining like satin; these sit pretty close to the stalks; between these the flowers come out in thick clusters from the side of the stalks; they are white, and are succeeded by roundish berries having one hard seed. This flowers here in June, but doth not produce ripe seeds.

The fifth sort grows on the mountains near Geneva, and in other parts of Italy, where it rises about three feet high; the flowers of this come out in clusters from the side of the branches, early in the spring. The leaves are spear-shaped, ending in blunt points, and are hoary on their under side. The flowers are succeeded by small roundish berries, which turn red when ripe.

The sixth sort grows naturally on the Alps, as also upon the mountains near Verona, from whence it was sent me; this is a very humble shrub, seldom growing more than one foot high, with ligneous stalks, which put out several side branches; these are garnished with narrow spear-shaped leaves, which are placed round the stalks without order; the branches are terminated by small clusters of purple flowers which stand erect, having no foot-stalks; the tubes of these flowers are longer and narrower than those of the Mezereon, and the mouth is cut into four acute parts which are erect. These flowers emit a pleasant odour; they appear early in the spring, but do not produce seeds here.

The seventh sort grows naturally about Montpellier; this rises with a shrubby stalk about two feet high, dividing into many small branches, which are closely garnished with narrow spear-shaped leaves growing erect, ending in acute points; the ends of the branches are terminated by panicles of flowers, which are much smaller than those of the Mezereon, having swelling tubes, which are contracted at the mouth. These appear in June, but are not succeeded by seeds here.

The eighth sort grows naturally at the Cape of Good Hope; this shrub rises to the height of five or six feet, dividing upward into several branches which grow erect, and are covered with a white bark, and closely garnished with small narrow leaves, which come out on every side of the branches without order, spreading open; the tops of the branches are terminated by woolly heads, out of which the flowers come in small clusters; they are white, having oblong tubes, which are divided into four obtuse segments at the mouth, which spread open. These plants do not produce seeds in Europe.

The ninth sort grows naturally in many islands in the West-Indies, it was sent me from Antigua. This shrub rises to the height of four or five feet, with a woody stalk, covered with a rugged bark of an Ash colour; the upper part of the branches are garnished

with leaves about the size, and the same form as those of Rosemary; between the leaves the flowers come out in small bunches, upon foot-stalks an inch long; they have short tubes cut into four parts at the top, and are white; these are succeeded by small round berries, of a brown colour when they are ripe.

The third, fourth, and seventh sorts are hardy, so will live through the winters in England in the open air, provided they are in a dry soil and a warm situation. The fifth and sixth sorts are as hardy as the common Mezereon, so are not in danger of being hurt by frost in England; but they are all very difficult to keep in gardens, because neither of them will bear to be transplanted. I have several times raised the plants from seeds, which have succeeded well in the places where they were sown, but whenever they were removed, they certainly died, though performed at different seasons, and with the greatest care, and the same has happened to every other person who has raised any of these plants; and some of my correspondents have assured me, they have frequently attempted to remove these plants from their natural places of growth, into their gardens, and have chosen plants of all sizes, from the youngest seedlings to the oldest plants, yet have never succeeded in it; though they have used their utmost care, and have performed it at different seasons. Therefore those who are desirous to have these plants in their gardens, must procure their seeds from the countries where they naturally grow; and when they arrive, they should be immediately sown where they are designed to remain, which for the third, fourth, and seventh sorts, should be on a very warm dry border, where, if there is a foundation of lime, rubbish, or chalk, under the upper surface of the ground, the plants will thrive better and continue much longer, than in better ground; and all the culture they require, is to keep the place clean from weeds, for the less the ground is stirred near their roots, the better the plants will thrive; for they naturally grow on poor shallow land, and out of crevices in rocks; so the nearer the soil approaches to this, the more likely the plants will be to succeed.

The fifth and sixth sorts may have a cooler situation; if these are sown where they may have only the morning sun, they will thrive better than in a warmer situation, and the ground near the roots of these should not be disturbed; therefore in the choice of the situation, there should be regard had to this, not to sow them near other plants, which may require transplanting, or to have the ground dug and loosened. The seeds of these plants coming from distant countries, rarely arrive here time enough to sow in autumn, so that when they are sown in the spring, the plants do not appear till the succeeding spring; and I have sometimes had the seeds remain till the second spring in the ground, before the plants have appeared; but as this may be too long for many people to leave the ground undisturbed, so they had better put the seeds into small pots of earth, and bury them in the ground the first summer, and in autumn take them up, and sow them where they are to stand; by this method, the seeds will be forwarded to vegetate the following spring.

The fifth sort is a beautiful sweet shrub, so deserves a place in gardens, as much as any of those we cultivate for ornament. The first and second sorts are sometimes used in medicine as was before observed, but being of a very caustic nature, are seldom prescribed; but if proper trials were with caution made, it is not doubted but they may be found very efficacious in many stubborn disorders, for some very ignorant quacks have performed great cures with these plants. The seventh sort produces the *Grana gnitida* of the shops.

The eighth sort grows naturally at the Cape of Good Hope, so will not live abroad in winter in England, but requires a good green-house to preserve it. This plant is very difficult to keep or propagate in gardens.

The ninth sort will not thrive in England, unless it is preserved in the bark-stove; this plant will not bear transplanting, for I raised several from seeds which thrived pretty well while they continued in the pot where they were sown, but when they were transplanted, they all decayed.

DATISCA. Lin. Gen. Plant. 1003. Cannabina. Tourn. Cor. 52. Bastard Hemp.

The CHARACTERS are,

It is male and female in different plants; the male flowers have an empalement composed of five narrow acute leaves; these have no petals, and scarce any visible stamina, but have ten summits which are much longer than the empalement. The female flowers have no petals, but the empalements are the same as the male, having an oblong pervious germen, supporting three styles, crowned by single stigmas; the empalement afterward becomes an oblong triangular capsule, opening with three valves, having one cell filled with small seeds, adhering to the three sides of the capsule.

This genus of plants is ranged in the tenth section of Linnæus's twenty-second class, intitled Diœcia Dodecandria, from the male and female flowers growing in separate plants, and the male flowers having ten stamina.

The SPECIES are,

1. DATISCA (Cannabina) caule lævi. Lin. Sp. Plant. 1037. Datisca with a smooth stalk. Cannabina Cretica florifera & fructifera. Tourn. Cor. 52.

2. DATISCA (Hirta) caule hirsuto. Lin. Sp. Plant. 1037. Datisca with a rough stalk.

The first sort grows naturally in Crete, and some other eastern countries. This hath a perennial root, from which arise several herbaceous stalks, about four feet high, garnished with winged leaves placed alternately, each being composed of three pair of lobes, terminated by an odd one; these are two inches long and half an inch broad, ending in acute points, and are deeply sawed on their edges, of a light green. The flowers come out in long loose spikes from the upper part of the stalks at the wings of the leaves, but having no petals, make but a poor appearance. The summits of the male flowers being pretty long, and of a bright yellow colour, are the only visible parts of the flowers to be discerned at any distance.

The flowers on the female plants are succeeded by oblong three-cornered capsules, filled with small seeds, which adhere to the three valves. The plants flower in June, and the seeds ripen in September. The stalks decay in autumn and new arise in spring.

This sort may be propagated by parting the roots, which should be performed in autumn when the stalks decay, (which is the best time to transplant the roots), but they must not be parted too small; they may be planted in any open beds, where they are not under the drip of trees, and will require no other culture but to keep them clean from weeds.

It may also be propagated by seeds, but these should be taken from such plants as grew in the neighbourhood of male plants, otherwise they will not succeed; and if the seeds are not sown in autumn, they seldom grow the first year. The seedling plants when they rise, will require no other care but to keep them clean from weeds till autumn, when they may be transplanted where they are to grow.

The second sort grows naturally in Canada, and other parts of North America. This differs from the former, in having hairy stalks, which grow taller; the leaves are larger, and do not stand so near each other upon the stalks. It is equally hardy with the first sort, and may be propagated in the same manner, but should have a more shady situation and a moister soil.

DATURA. Lin. Gen. Plant. 218. Stramonium. Tourn. Inst. R. H. 118. Thorn Apple.

The CHARACTERS are,

The flower is of one petal which is funnel-shaped, having a long cylindrical tube; spreading open at the top, which in some species is pentangular, each angle being pointed; the empalement of the flower is permanent, swelling in the middle, five-cornered, and tubulous; the flower hath

five stamina, which are as long as the empalement, terminated by oblong compressed summits; it hath an oval germen, supporting an upright style, crowned by a thick obtuse stigma. The germen afterward becomes an oval capsule, divided into four cells by a cross intermediate partition, which are filled with kidney-shaped seeds adhering to the partition.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. DATURA (Stramonium) pericarpis spinosis erectis ovatis, foliis ovatis glabris. Hort. Cliff. 55. Datura with an oval erect fruit having a prickly cover. Stramonium fructu spinoso rotundo, flore albo simplici. Tourn. Inst. R. H. 118. Thorn Apple with a round prickly fruit, and a single white flower.

2. DATURA (Tatula) pericarpis spinosis erectis ovatis, foliis cordatis glabris dentatis. Lin. Sp. 256. Datura with an erect oval fruit with a prickly cover, and smooth, heart-shaped, indented leaves. Stramonium fructu spinoso oblongo, flore violaceo. Tourn. Inst. R. H. 119. Thorn Apple with an oblong prickly fruit, and a Violet-coloured flower.

3. DATURA (Metel) pericarpis spinosis nutantibus globosis, foliis cordatis subintegris pubescentibus. Hort. Cliff. 55. Datura with a globular nodding fruit having a prickly cover, and heart-shaped, entire, hairy leaves. Datura alba. Rump. 5. p. 242.

4. DATURA (Ferox) pericarpis spinosis erectis ovatis, spinis supremis maximis convergentibus. Amœn. Acad. 3. p. 403. Datura with an oval erect fruit, whose upper spines are largest, and converge together. Stramonium ferox. Bocc. 50. Rough Thorn Apple.

5. DATURA (Inoxia) pericarpis spinosis inoxiis ovatis pro-pendentibus, foliis cordatis pubescentibus. Datura with an oval hanging fruit, whose cover is beset with harmless spines, and heart-shaped hairy leaves. Stramonium folio hyoscyami, flore toto candido, fructu propendente rotundo, spinis inoxiis ornato. Boerh. Ind. alt. 1.

6. DATURA (Fastuosa) pericarpis tuberculosis nutantibus globosis, foliis lævibus. Lin. Sp. 256. Datura with a globular nodding fruit, whose cover is set with tubercles and soft leaves. Stramonium Ægyptiacum flore pleno, intus albo, foris violaceo. Tourn. Inst. 119. Egyptian Thorn Apple with a double flower, white on the inside, and Violet-coloured on the outside.

7. DATURA (Arborea) pericarpis inermibus nutantibus, caule arboreo. Lin. Sp. Plant. 179. Datura with a nodding fruit having an unarmed cover, and a tree-like stalk. Stramoniodes arboreum, oblongo & integro folio, fructu lævi, vulgò. Flori pondio. Feuil. tab. 46. The first sort here enumerated is the most common Thorn Apple in Europe, and was probably first introduced from Italy or Spain, where it naturally grows; but it is now become so common about London, and near other great towns in England, as to appear like a native plant; for there are few gardens or dunghills without this plant in summer, though it is only near such places, where the plants may have been cultivated first in the gardens; and wherever any of these plants are permitted to seed, they will furnish a supply of the plants for some years to come, as they produce a vast quantity of seeds, some of which will lie years in the ground, and when they are turned up to the air will vegetate.

This sort seldom grows much more than two feet high, dividing into many strong irregular branches which are hollow, garnished with large smooth leaves divided into irregular angles, and emit a foetid odour. The flowers come out first from the forks or divisions of the branches, and afterward near the extremities of the branches; they have long swelling tubes, which are dilated at the top into large pentagonal brims, each angle ending in a long point or ligula; these stand in long, green, five-cornered empalements, and are succeeded by large roundish seed-vessels, covered with strong thorns, divided by four furrows, to which adhere the partitions, which separate the four cells, filled with black kidney-shaped seeds. It flowers in July, August, and September, and the seeds ripen

in autumn, which, if permitted to scatter, will fill the ground about them with plants the following years. There was formerly a cooling ointment made with the leaves of this plant and hogs lard, which was greatly esteemed for burns and scalds.

There is a variety (if not a distinct species of this) which grows naturally in North America; the plants of this grow more than twice the size of the former; the leaves are smoother, and of a lucid green, but the flowers and fruit are of the same form as those of the other, so may be deemed a distinct species, especially as the difference continues in the plants propagated in England.

The second sort grows naturally in most parts of America, for I have frequently received the seeds of it from the islands in the West-Indies, and also from all the northern parts of America. This rises with a purple strong stalk to the height of four or five feet, dividing into many strong branches, garnished with leaves shaped somewhat like those of the former sort, but larger, and have a greater number of angles and lacinæ on their edges; the flowers have longer and narrower tubes, and are of a purple colour; the fruit is also longer, and these differences are permanent. This is equally hardy with the former, and if the seeds are permitted to scatter, the plants will become troublesome weeds. The third sort hath a strong stem, which rises three feet high, and divides into many woolly branches; the leaves of this sort are almost entire, having only two or three slight indentures on their edges; the flowers have long tubes, which extend beyond the bifid empalement, then they spread out very broad, where the brim is divided into ten obtuse angles; they are of a pure white above, but the tubes have a tincture of green within. These are succeeded by roundish fruit, closely covered with thorns, and are divided into four cells as the other, but the seeds of this are of a light brown colour when ripe.

This plant is not so hardy as the others, so the seeds must be sown upon a gentle hot-bed in the spring, and the plants must be afterward treated in the same manner as the Marvel of Peru, and other of the hardier kinds of annual plants, and may be transplanted into the full ground the latter end of May. They will flower in July, and the seeds will ripen in autumn.

There is a variety of this with double flowers, but unless the plants of this are placed in a glass-case, they will not produce seeds in this country.

The fourth sort is of humbler growth, seldom rising more than a foot and a half high, spreading out into many branches, which are garnished with leaves somewhat like those of the first sort, but are smaller, and stand upon longer foot-stalks; the flowers are like those of the first sort, but smaller; the fruit is round, and armed with very strong sharp thorns, the upper being large, and converge toward each other. The seeds of this are black when ripe.

This sort is too tender to be sown in the full ground in England, so the plants should be raised on a hot-bed, and afterward transplanted into borders as the former sort.

The fifth sort grows naturally at La Vera Cruz, from whence I received the seeds. This rises with a purplish stem three or four feet high, dividing into several strong branches, garnished with oblong heart-shaped leaves. The stalks, branches, and leaves of this sort are covered with soft hairs; the flowers come out at the division of the stalks and branches, standing erect; they are large, white, and are succeeded by oval fruit, covered with long, soft, innocent spines, opening in four cells, which are full of brown seeds.

This plant is annual, and should be first raised on a moderate hot-bed, then may be transplanted into open borders, where it will flower and perfect its seeds in the autumn. If these seeds are permitted to scatter, the plants will rise the following spring, and if the summer proves warm, they will flower and often perfect their seeds.

The sixth sort grows naturally in Egypt, and also in India. This rises with a fine polished purple stalk four

feet high, dividing into several branches, which are garnished with large, smooth, sinuated leaves, standing upon pretty long foot-stalks. The flowers are produced at the divisions of the branches; these have large swelling tubes, which expand very broad at the top, their brims being divided into ten angles, each ending with a long slender point. The flowers are of a beautiful purple on their outside, and a satiny white within; some of these are single, others have two or three flowers standing one within another, and some are double, having four or five petals within each other of equal length, so as to appear a full flower at the brim; they have an agreeable odour at first, but if long smelt to, become less agreeable, and are narcotic. If these plants are brought forward upon a hot-bed in the spring, and in June planted out on a warm border of rich earth, they will flower very finely in July and August; but unless they are covered with glasses, the seeds seldom ripen well in England. The fruit of this sort is round, and grows nodding downward; the seed-vessel is thick and fleshy, as are also the intermediate partitions which divide the cells. The outside of the fruit is covered with blunt protuberances, and the seeds are of a bright brown colour when ripe.

The seventh sort was sent me from La Vera Cruz by the late Dr. Houstoun, who found it growing there naturally. This rises with a woody stalk to the height of twelve or fourteen feet, dividing into several branches, which are garnished with oblique leaves six inches long, and two inches and a half broad in their broadest part, growing narrower at each end; they are oblique to the foot-stalk, which stands nearer to one side than the other; they are downy, and stand upon long foot-stalks. The flowers come out at the division of the branches; these have a loose tubular empalement near four inches long, which opens at the top on one side like a spatha or sheath, within the empalement; the tube of the flower is narrow, but immediately above it swells very large for near six inches in length, then spreads open at the brim, where it is divided into five angles, which terminate in very long points; they are white, with some longitudinal stripes, of a pale yellow on their outside; these are succeeded by round smooth capsules, filled with kidney-shaped seeds.

This tree is one of the greatest ornaments to the gardens in Chili, where the inhabitants propagate it with great care. When the flowers are fully blown, they make a fine appearance, and a single tree will perfume the air of a large garden.

This plant is tender, so requires to be kept in a stove in England. The seeds of this must be procured from the places where the trees naturally grow; they should be perfectly ripe when gathered, and carefully put up, so as that the vermin cannot get to them, for they will destroy them. Most of the seeds which were sent over by Dr. Houstoun, were devoured in their passage by insects, so that but few plants were raised. There were two or three of them raised in the gardens of the late Lord Petre, and two in the Chelsea garden; one of which came so far as to flower, but perished without producing seeds, so that at present I believe there is not any of the plants in England.

DAUCUS. Lin. Gen. Plant. 296. Tourn. Inst. R. H. 307. tab. 161. [*δαῦκος*], which some derive of *δαίω*, Gr. to burn, of its sharp and fiery power, or fervent taste.] The Carrot.

The CHARACTERS are,

It hath an umbelliferous flower; the principal umbel is composed of a great number of small ones called rays, which are short, and in clusters. The involucre of the principal umbel is composed of many narrow leaves, having winged points; these are scarce so long as the umbel; those of the rays are shorter and simple. The flowers have five heart-shaped petals which turn inward; those which compose the rays are unequal in size, but those of the disk are nearly so; these have each five hairy stamina, terminated by roundish summits. The germen sits under the flower, support-

supporting two reflexed styles, crowned by obtuse stigmas. The germen afterward becomes a small, roundish, striated fruit, dividing in two parts, each having a single seed, convex and furrowed on one side, and plain on the other. This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. DAUCUS (*Sylvestris*) feminibus hispida, radice tenuiore fervido. Carrot with a prickly seed, and a slender bot root. Daucus vulgaris. Clus. Hist. 2. p. 198. Common wild Carrot.
2. DAUCUS (*Carota*) feminibus hispida, radice carnosofcumento. Carrot with a prickly seed, and a fleshy eatable root. Daucus fativus, radice aurantii coloris. Tourn. Inst. R. H. 307.
3. DAUCUS (*Gingidium*) radiis involucri planis, laciniis recurvis. Prod. Leyd. 97. Carrot with plain rays to the involucre, and recurved jags. Daucus montanus lucidus. Tourn. Inst. 307. Shining maritime Carrot.
4. DAUCUS (*Hispidus*) caule hispido, segmentis foliorum latoribus. Carrot with a prickly stalk, and broader segments to the leaves. Pastinaca Oenanthes folio. Bocc. Rar. Pl. 75. Parsnep with a Water Dropwort leaf.
5. DAUCUS (*Creticus*) radiis involucri pinnatifidis, umbellis duplo longioribus, foliolis acutis. Carrot with wing-pointed rays to the involucre, which are twice the length of the umbel, and acute leaves. Daucus tenuifolius Creticus, radiis umbellæ longioribus. Tourn. Inst. R. H. 308. Narrow-leaved Carrot of Crete, with rays longer than the umbel.
6. DAUCUS (*Mauritanicus*) feminibus hispida, flosculo centrali sterili carnosof, receptaculo communi hemisphærico. Lin. Sp. 348. Carrot with hispid seeds, the central flower barren, and the common receptacle hemispherical. Daucus Hispanicus, umbella magna. Tourn. Inst. 308.
7. DAUCUS (*Visnaga*) feminibus nudis. Hort. Cliff. 89. Carrot having naked seeds. Gingidium umbella oblonga. C. B. P. 151. Gingidium with an oblong umbel.
8. DAUCUS (*Muricatus*) feminibus aculeatus. Lin. Sp. 349. Carrot with prickly seeds. Caucalis major Daucoides Tingitana. Mor. Hist. 3. p. 308.

The first sort is the common wild Carrot, which grows by the side of fields, and in pasture grounds in many parts of England. The plants of this sort do not differ greatly in appearance from the Garden Carrot, which has led some persons into an opinion of their being the same plant; but those who have attempted to cultivate the wild sort, are fully convinced of their being distinct plants. I have tried to cultivate the wild sort for many years, but could never get the seeds which were sown in the spring to grow, upon which I sowed the seeds in autumn, part of which have come up well; these plants I cultivated in the same manner as the Garden Carrot, but could not improve the roots in the least, for they continued to be small, sticky, and of a hot biting taste; and this has been always the case, wherever the plants have been sown, therefore there can be no doubt of their being different plants. The seeds of this sort are used in medicine, and are esteemed good to bring away gravel: it is an excellent diuretic, but instead of these seeds, the shops are usually supplied with old seeds of the Garden Carrot, when they have lost their vegetative quality, then the seedsmen sell them to the druggists for medicinal use; but certainly all seeds which are too old to grow, can have little virtue remaining in them.

There are several varieties of the Garden Carrots, which differ in the colour of their roots, and these variations may be continued, where there is proper care taken not to mix the different sorts together in the same garden; but the Orange Carrot is generally esteemed in London, where the yellow and the white Carrots are seldom cultivated.

The dark red, or purple Carrot, I take to be a distinct sort from either of these; but as it is much tenderer, I have not had an opportunity of seeing it in the flower, for the roots were all destroyed by the first

frosts in autumn. The seeds of this sort were sent me from Aleppo, which succeeded very well; the roots were not so large as those of the other sorts of Carrots, and were of a purple colour, very like that of a deep-coloured Radish; they were very tender and sweet; the leaves were finer cut than those of the common Carrot, and were less hairy.

The second sort is commonly cultivated in gardens for the kitchen, and the different varieties of it are; in some places, esteemed, though in London; the Orange Carrot is preferred to all the other.

They are propagated at two or three different seasons; or sometimes oftener, where people are fond of young Carrots, whenever they can be procured. The first season for sowing the seeds is soon after Christmas, if the weather is open, which should be in warm borders, near walls, pales, or hedges, but they should not be sown immediately close thereto; but a border of Lettuce, or other young fallad herbs, of about a foot wide, should be next the wall, &c. for if the Carrots were sown close to the wall, they would draw up weak, without making any tolerable roots.

These delight in a warm sandy soil which is light, and should be dug pretty deep, that the roots may the better run down; for if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral roots, especially where the ground is too much dunged the same year that the seeds are sown, which will also occasion their being worm-eaten; it is therefore the better method to dung the ground intended for Carrots the year before they are sown, that it may be consumed, and mixed with the earth; but in such places where there has not been ground so prepared the year before, and there may be a necessity for dunging it the same year as the Carrots are sown, the dung should be well rotted which is laid upon it, and should be thinly spread over the ground; and in the digging of it into the ground, great care should be taken to disperse it all through the ground, and not to bury it in heaps, for that will stop the roots of the Carrots in their downright growth, and cause them to be short and forked. Where the ground is inclinable to bind, there cannot be too much care taken to break and divide the parts; therefore in digging the land for Carrots, there should never be large spits taken, but they must be very thin, and the clods well broken; which, if not attended to by the master, is seldom properly performed by workmen, who are too apt to hurry over their work, if they are not well observed.

The ground when dug should be laid level and even; otherwise when the seeds are sown and the ground is raked over, part of the seeds will be buried too deep, and others will be in danger of being drawn up into heaps; so the plants will come up in bunches, and other parts of the ground be naked, which should always be carefully avoided.

The seeds have a great quantity of small forked hairs upon their borders, by which they closely adhere, so that they are difficult to sow even, so as not to come up in patches; you should therefore rub it well through both hands, whereby the seed will be separated before it is sown; then you should choose a calm day to sow it in, for if the wind blows, it will be impossible to sow it equal, for the seeds being very light, will be blown into heaps. When the seed is sown, you should tread the ground pretty close with your feet, that it may be buried, and then rake the ground level.

When the plants are come up and have got four leaves, you should hoe the ground with a small hoe about three inches wide, cutting down all young weeds, and separating the plants to four inches distance each way, that they may get strength; and in about a month or five weeks after, when the weeds begin to grow again, you should hoe the ground over a second time, in which you should be careful not to leave two Carrots close to each other, as also to separate them to a greater distance, cutting down all weeds, and slightly stirring the surface of the ground in every

place, the better to prevent young weeds from springing, as also to facilitate the growth of the young Carrots.

In about a month or five weeks after, you must hoe them a third time, when you must clear the weeds as before; and now you should cut out the Carrots to the distance they are to remain, which must be proportioned to the size you intend to have them grow. If they are to be drawn while young, five or six inches asunder will be sufficient, but if they are to grow large before they are pulled up, they should be left eight or ten inches distant every way; you must also keep them clear from weeds, which, if suffered to grow amongst the Carrots, will greatly prejudice them.

The second season for sowing these seeds is in February, on warm banks, situated near the shelter of a wall, pale, or hedge; but those which are intended for the open large quarters, should not be sown before the beginning of March, nor should you sow any later than the end of the same month; for those which are sown in April or May, will run up to seed before their roots have any bulk, especially if the weather should prove hot and dry.

In July you may sow again for an autumnal crop, and at the end of August you may sow some to stand the winter; by which method you will have early Carrots in March, before the spring sowing will be fit to draw; but these are seldom so well tasted, and are often very tough and sticky. However, as young Carrots are generally expected early in the spring, most people sow some at this season; but these should be sown upon warm borders and dry land, otherwise they are seldom good. If the winter should prove very severe, it will be proper to cover the young Carrots with Pease-haulm, the haulm of Asparagus, or some such light covering, to prevent the frost from penetrating into the ground, which often destroys the Carrots, where this care is wanting: but if in very hard winters the Carrots should be all destroyed which were sown in autumn, there should be a hot-bed made early in the spring to sow some, which will be fit for use long before any that are sown in the full ground; but these beds should be earthed fifteen or sixteen inches deep, that the roots may have a proper depth of soil to run down. If these beds are lined with hot dung twice, at such times when the heat of the beds decline, it will greatly forward the growth of the Carrots, but there should be great care taken not to draw the plants up too weak; these may be allowed to grow closer together than those sown in the full ground, because they will be drawn for use very young. Many people mix several other sorts of seeds, as Leek, Onion, Parsnep, Radish, &c. amongst their Carrots; and others plant Beans, &c. but, in my opinion, neither of these methods are good; for, if there is a full crop of any one of these plants, there can be no room for any thing else amongst them, so that what is got by one is lost by another; and besides, it is not only more slightly, but better, for the plants of each kind to be sown separate; and also by this means your ground will be clear, when the crop is gone, to sow or plant any thing else; but when three or four kinds are mixed together, the ground is seldom at liberty before the succeeding spring: besides, where Beans, or any other tall-growing plants are planted amongst the Carrots, they are apt to make them grow more in top than root; so that they will not be half so large as if sown singly, without any other plants amongst them.

The covetousness of some gardeners will not permit them to cut out their Carrots to a proper distance when they hoe them, so that by leaving them close, they draw each other up weak: and if they are drawn while young, they never recover their strength afterward so perfectly, as to grow near the size of those which are properly thinned at the first hoeing; therefore where the Carrots are designed to have large roots, they must never stand too close, nor should they have any other crop mixed with them.

This root has been long cultivated in gardens for the table, but has not till of late years been cultivated in the fields for cattle, nor has it been practised as yet but in few parts of England; it is therefore greatly to be wished, that the culture of it was extended to every part of England, where the soil is proper for the purpose; for there is scarce any root yet known, which more deserves it, being a very hearty good food for most sorts of animals. One acre of Carrots, if well planted, will fatten a greater number of sheep or bullocks, than three acres of Turneps, and the flesh of these animals will be firmer and better tasted. Horses are extremely fond of these roots, and for hogs there is not any better food. I have also known these roots cultivated for feeding of deer in parks, which has proved of excellent use in hard winters, when there has been a scarcity of other food; at which times great numbers of deer have perished for want, and those which have escaped, have been so much reduced, as not to recover their flesh the following summer; whereas, those fed with Carrots have been kept in good condition all the winter, and upon the growth of the grass in the spring, have been fat early in the season, which is an advantage, where the grass is generally backward in its growth.

There is also an advantage in the cultivation of this root beyond that of the Turnep, because the crop is not so liable to fail; for as the Carrots are sown in the spring, the plants generally come up well, and unless the months of June and July prove very bad, there is no danger of the crop succeeding; whereas Turneps are frequently destroyed by the flies at their first coming up, and in dry autumns they are attacked by caterpillars, which in a short time devour whole fields, but Carrots are not attacked by these vermin: therefore every farmer who has a stock of cattle or sheep, should always have a supply of these roots, if he has land proper for the purpose, which must be light, and of a proper depth to admit of the roots running down.

In preparing the land for Carrots, if it has not been in tillage before, it should be ploughed early in autumn, and then ploughed across again before winter, laying it up in high ridges to mellow by the frost; and if the ground is poor, there should be some rotten dung spread over it in winter, which should be ploughed in about the beginning of February; then in March, the ground should be ploughed again to receive the seeds; in the doing of which, some farmers have two ploughs, one following the other in the same furrow, so that the ground is loosened a foot and a half deep. Others have men with spades following the plough in the furrows, turning up a spit of earth from the bottom, which they lay upon the top, levelling it smooth and breaking the clods; the latter method is attended with a little more expence, but is much to be preferred to the first, because in this way the clods are more broken, and the surface of the ground is laid much even.

If the land has been in tillage before, it will require but three ploughings; the first just before winter, when it should be laid in high ridges for the reasons before given; the second cross ploughing should be in February, after which, if it is well harrowed to break the clods, it will be of great service; the last time must be in March to receive the seeds, this should be performed in the manner before mentioned. After this third ploughing, if there remain great clods of earth unbroken, it will be proper to harrow it well before the seeds are sown. One pound and a half of seeds will be sufficient for an acre of land, but as they are apt to adhere together, it renders them more difficult to sow even than most other sorts; therefore some mix a quantity of dry sand with their seeds, rubbing them well together, so as to separate the Carrot seeds from each other, which is a good method. After the seeds are sown, they must be gently harrowed in to bury them; and when the plants come up, they should be hoed in the manner before directed.

But

D A U

But in order to preserve your Carrots for use all the winter and spring, you should, about the beginning of November, when the green leaves are decayed, dig them up, and lay them in sand in a dry place, where the frost cannot come to them, taking them out from time to time as you have occasion for them, reserving some of the longest and straightest roots for seed, if you intend to save any; which roots should be planted in the middle of February, in a light soil, about a foot asunder each way, observing to keep the ground clear from weeds; and about the middle of August, when you find the seeds are ripe, you must cut it off, and carry it to a dry place, where it should be exposed to the sun and air for several days to dry; then you may beat out the seeds, and put it up in bags, keeping it in a dry place until you use it. This seed is seldom esteemed very good after the first or second year at most, but new seed is always preferred, nor will it grow when it is more than two years old.

The third sort grows naturally about Montpellier; this hath smoother stalks than the common Carrot, the segments of the leaves are broader, and of a lucid green; the umbels of the flowers are larger, and not so regular. This is an annual plant, but it succeeds best when sown in autumn.

The fourth sort is of lower growth than either of the former; the stalks are closely covered with short prickles, the segments of the leaves are broad and obtuse, the umbels are small, and the involucre is longer than the umbel, and the leaves are trifid which compose it.

The fifth sort rises with a slender, rough, hairy stalk upward of two feet high; the leaves are short, and have a few small ones intermixed, which are thinly placed, and cut into acute segments; the umbels are not so large as those of the common sort, and the involucre is twice the length of the umbel; the leaves which compose it are divided into five or seven parts, ending in acute points; the flowers are yellow.

The sixth sort hath a channelled stalk rising near three feet, which is terminated by large umbels of flowers, with a wing-pointed involucre; the segments of the lower leaves are cut into obtuse segments, and are of a deep green colour.

The seventh sort is an annual plant, which grows naturally in Spain and Italy; this rises with an upright, smooth, channelled stalk three feet high, garnished with smooth leaves, which are divided into many fine narrow segments like those of Fennel; the stalks branch out upward, and each branch is terminated by a large umbel, composed of a great number of small ones; the involucre is shorter than the umbel, and each of the leaves which compose it is trifid: the foot-stalks which sustain the small umbels (or rays) are long and stiff; these are by the Spaniards used for picking their teeth, from whence the plant had the title of *Visnaga*, or *Pick-tooth*. The seeds of this plant should be sown in autumn, for those which are sown in the spring frequently fail, or at least remain in the ground till next year before they grow; the plants require no other culture but to keep them clean from weeds, and thin them where they are too close.

The eighth sort grows naturally about Tangier. This rises with an upright stalk above two feet high, garnished with double-winged leaves which are hairy; the stalk branches upward into several divisions, each being terminated by an umbel of white flowers, which are succeeded by prickly seeds.

If the seeds of this sort are not sown in the autumn, the plants rarely perfect their seeds in this country; for when they are sown in the spring, and the plants come up soon after, they generally run up to seed in autumn, so that the frosts come on before they have time to ripen.

These sorts are sometimes preserved in botanic gardens for the sake of variety, but being of no use, are not cultivated in other gardens.

DAUCUS CRETICUS. See **ATHAMANTA**.

D A Y

D'AYENIA; Monier.

This genus of plants receives its title from Monseigneur Le Duc D'Ayen, who is a great lover and promoter of the science of botany; and has a noble garden at St. Germain, which is well stored with rare plants from many different parts of the world, and has appointed Dr. Monier, member of the Royal Academy of Sciences, the superintendent of it.

The **CHARACTERS** are;

It hath an empalement composed of five small oval leaves which are dry. The flower hath five petals, whose points are united to a plain starry nectarium; the nectarium sits upon a cylindrical column which is erect, and the length of the empalement; it is bell-shaped, having five depressed lobes at the margin: it hath five short stamina inserted into the border of the nectarium, terminated by roundish summits, which are joined to the border of the petals. It hath a roundish germen in the bottom of the nectarium, supporting a cylindrical style, crowned by a five-cornered obtuse stigma. The capsule hath five cells, inclosing five oblong seeds fastened to the capsule.

This genus of plants is ranged in the fourth section of Linnæus's twentieth class, intitled *Gynandria Pentandria*, the flowers having five stamina, which are fastened with the style to the nectarium.

We at present know but one **SPECIES** of this genus, viz.

D'AYENIA (*Pusilla*) *foliis cordatis glabris.* Lin. Sp. 1354.
D'Ayenian with heart-shaped smooth leaves.

The seeds of this plant were sent by the younger De Jussieu from Peru to Paris, where they succeeded, and have since been communicated to many other gardens in Europe. I received the seeds from Dr. Monier, intendent of the garden of the Duke D'Ayen at St. Germain, which have for some years grown in the Chelsea garden, where the plants annually flower and perfect their seeds.

This plant hath a weak ligneous stalk, which divides into several slender branches, rising from nine inches to a foot high, garnished by heart-shaped smooth leaves, which are slightly indented on their edges, standing upon pretty long foot-stalks; they are of a lucid green, and end in acute points, placed alternately on the branches. At the base of each foot-stalk, from the side of the branches, come out the flowers, two, three, or four, arising from the same point, each standing upon a separate slender foot-stalk; they have five slender stamina, collected into a sort of column, like the malvaceous flowers, having a five-cornered germen at the bottom, which afterward becomes a roundish five-cornered capsule, having five cells, in each of these is lodged one kidney-shaped seed. The flowers are tubulous, spreading open at the top, where they are cut into five acute segments, each being terminated by a slender tail; they are purple, and continue in succession on the same plants from July to the winter.

This plant is propagated by seeds, which should be sown upon a moderate hot-bed early in the spring; and when the plants are come up, and have four leaves, they should be transplanted on a fresh hot-bed to bring them forward; part of them may be planted in small pots, and the others may be planted on the bed: those in the pots should be plunged into a hot-bed of tanners bark; they must be shaded till they have taken new root, then they must have free air admitted to them every day, in proportion to the warmth of the season; they require to be frequently watered in warm weather, but they should not have it in too great plenty. The plants should continue all the summer in the hot-bed, where they must have a good share of air; for those which are fully exposed to the open air will not thrive, and if they are too much drawn, they do not flower well. The plants will live through the winter in a moderate stove; but as they perfect their seeds well the first year, few persons care to continue the old plants. There is a figure of this plant exhibited in the 118th plate of our figures of plants.

DAY-LILY. See **HEMEROCALLIS**.

DECORTICATION, is the pulling off the outward bark of trees, also the peeling or barking of roots.

DELPHINIUM. Lin. Gen. Plant. 602. Tourn. Inst. R. H. 426. tab. 241. [*Δελφιν*, Gr. a dolphin; so called, because the flower, before it opens, resembles a dolphin. It is called *Consolida Regalis*, from its consolidating virtue. Caspar Bauhin calls it the Royal Plant, because it has its cup turned backwards, like a nobleman's badge. Cæsalpinus, Pliny, and the poets say, this plant is the true Hyacinth, because it has the syllable ai inscribed on its flower, which is a particle of bewailing,] Larkspur, or Larkheel.

The CHARACTERS are,

The flower hath no empalement; it is composed of five unequal petals placed circularly; the upper petal is extended at the hinder part into a tubular obtuse tail; the two side petals are nearly of the same size with the upper, but the two lower are smaller; these spread open. There is a bifid nectarium situated in the center of the petals, and is involved in the tube by the back part. The flower hath many small stamina which incline to the petals, and are terminated by small erect summits; it hath three oval germen, supporting three styles which are as long as the stamina, crowned by reflexed stigmas; the germen afterward become so many capsules joined together, which open crossways, each having one cell filled with angular seeds.

This genus of plants is ranged in the third section of Linnæus's thirteenth class, intitled Polyandria Trigynia, the flower having many stamina and three styles

The SPECIES are,

1. **DELPHINIUM** (*Consolida*) nectariis monophyllis, caule subdiviso. Hort. Cliff. 217. *Larkspur with a one-leaved nectarium and a divided stalk.* Delphinium fegetum. Tourn. Inst. 426. *Corn Larkspur, and the Consolida regalis arvensis.* C. B. P. 142. *Field Royal Consound.*
2. **DELPHINIUM** (*Ascia*) nectariis monophyllis, caule simplici. *Larkspur with a one-leaved nectarium, and an erect stalk.* Delphinium hortense, flore majore & simplici cæruleo. Tourn. Inst. R. H. 426. *Garden Larkspur, with a larger single blue flower.*
3. **DELPHINIUM** (*Ambiguum*) nectariis monophyllis, caule ramoso. *Larkspur with a one-leaved nectarium and a branching stalk.* Delphinium elatius purpureo violaceum. Suvert. Flor. *Branched Larkspur.*
4. **DELPHINIUM** (*Peregrinum*) nectariis diphyllis corollis enneapetalis capsulis teretis, foliis multipartitis obtusis. Hort. Cliff. 213. *Larkspur with a two-leaved nectarium, a flower with eleven petals and three capsules, and leaves divided into many obtuse segments.* Delphinium latifolium, parvo flore. Tourn. Inst. R. H. 426. *Broad-leaved Larkspur with a small flower.*
5. **DELPHINIUM** (*Elatum*) nectariis diphyllis, labellis bifidis, apice barbatis, foliis incisiss, caule erecto. Hort. Upsal. 151. *Larkspur with a two-leaved nectarium, a bifid lip bearded at the top, cut leaves, and an erect stalk.* Delphinium perenne montanum villosum, aconiti folio. Tourn. Inst. 426. *Perennial hairy Mountain Larkspur with a Monkshood leaf, commonly called the Bee Larkspur.*

The several varieties of the Garden Larkspur are not here enumerated, as they would swell the work beyond its intended bulk, if all these were distinguished, therefore here are only the distinct species mentioned; and as the gardeners distinguish the Garden Larkspurs into those which are branched, and such as have upright stalks; which difference is permanent, and never alters, whatever may be asserted to the contrary by ignorant pretenders; so I shall just mention the several varieties which there are of each sort, commonly cultivated in the gardens of the curious. And first of the branched Larkspur, there are of the following colours, with single and double flowers.

Blue, purple, white, flesh, Ash, and Rose colours; and some have flowers beautifully spotted, with two or three of these different colours.

The upright or unbranched Larkspur, produces a greater variety of colours than the branched, and the flowers are larger and fuller than those; but the principal colours run nearly the same with those of the other, though many of the colours are deeper, and there are more different shades of these colours in the flowers of this sort.

The first sort grows naturally on arable lands, in France, Spain, and Italy, and is supposed to be the same as the Garden Larkspur, which is a great mistake; for I have cultivated it many years in the garden, and never found it alter: the leaves of this sort are broader, and not so much divided as those of the garden kind, and are placed thinner upon the stalks; the flowers are smaller, and grow in longer spikes; the stalks are not so much branched as that sort which is called the branched, nor are they single like the upright, so that I think it may be allowed to be a different species.

The second sort hath upright stalks, which scarce put out any branches; the spikes of flowers grow erect, and the flowers are placed very close together, so that they make a fine appearance. These plants flower in July and August, and are very great ornaments to the borders of the flower-garden.

The branching Larkspur, which is the third sort, comes later to flower than the upright; this rises with a very branching stalk three feet high or more; the branches come out horizontally from the side of the stalks, but afterward turn that part on which the spike of flowers grow, which is at the extremity upward, so as to make an angle; the leaves are long and finely divided; the flowers are placed thinner in the spikes than those of the upright sort; they are large, and some of them very double and of various colours.

These plants are annual, so are every year propagated by seeds, which should be sown where the plants are designed to remain, for they do not bear transplanting well, especially if they are not removed very young; those seeds which are sown in autumn, produce the strongest plants and most double flowers, and ripen their seeds better than those which are sown in the spring, as they come earlier to flower; but to continue a succession of these flowers, there should be some seeds sown in the spring. When they are sown on the borders of the flower-garden for ornament, they should be in patches of about a foot diameter, in the middle of the borders, at proper distances; in each of these patches may be scattered ten or a dozen seeds, covering them over about a quarter of an inch with earth; and in the spring the plants may be thinned, leaving about five or six of the upright sort in each patch to stand for flowering; but of the branching sort, not more than three or four, because these require room; after this the plants will require no farther care but to keep them clean from weeds, and when they begin to flower should be supported by flower-sticks to prevent their being broken by wind, especially if they are not in a sheltered situation. If the seeds were well chosen, there will be very few ordinary

ordinary flowers among them; and if there are seeds of the different coloured flowers sown in each patch, they will make a pleasing variety: but the upright sort should never be mixed in the same patches with the branching, because they do not flower at the same time.

But in order to preserve the two sorts fine without degenerating to single or bad colours, there should be a bed of each sort sown in autumn, in some separate part of the garden, where the plants should be properly thinned, and kept clean from weeds, till they begin to shew their flowers; when they should be carefully looked over every other day, to pull out all those plants, whose flowers are not very double nor of good colours; for if these are permitted to stand among the others till their farina has impregnated them, it will certainly cause them to degenerate; so that those persons who are contented with only marking their good flowers for seed, and suffer the others to stand for seed among them, will always find themselves disappointed in the goodness of their flowers the following season: therefore those who propose to have these flowers in perfection, should never gather the seeds of such as grew in the borders of the flower-garden; because there it will be almost impossible to preserve them so true, as when they are in beds at a distance from all other kinds.

When the seed-vessels turn brown, they must be carefully watched, to gather them before they open and discharge the seeds; so that those which are situated on the lower part of the stalk, will open long before those on the upper part of the stalk are ripe; for which reason the pods should from time to time be gathered as they ripen, and not suffered to stand till the stalks are pulled up, which is often practised. Those pods which are situated on the lower part of the stalks, are much preferable to such as grow near the top; for which reason those who are very curious in the choice of their seeds, crop off the upper part of the spikes of flowers, and never suffer them to stand for seeds.

As these plants are very hardy, and require so little care in their culture, so they are worthy of a place in every good garden; for during their continuance in flower, there are few plants which make a better appearance; and for gathering to make flower-pots to adorn rooms, there is scarce any flower so proper; because by their upright growth and long spikes, they rise to a proper height above the pots; and when the several colours are skilfully intermixed they make a rich appearance, and continue long in beauty.

The fourth sort grows naturally in Sicily and Spain, I received the seeds of it from Gibraltar; this hath a very branching stalk, which rises about two feet high; the lower leaves are divided into many broad obtuse segments, but those which are upon the stalks are generally single; the flowers grow scatteringly toward the upper part of the branches, they are small, and of a deep blue colour; these are succeeded by very small seed-vessels, which are sometimes single, and at others double, and very rarely three together, as in the common sorts. This is an annual plant, whose seeds should be sown in autumn, and the plants treated as the common sort; it hath little beauty, and is only kept in some gardens for the sake of variety.

The fifth sort hath a perennial root, which sends out several upright stalks in the spring, rising to the height of four feet, garnished with leaves which are divided into many broad segments, in form of a spreading hand; these segments are cut at their extremities into two or three acute points; the leaves are hairy, and stand upon long foot-stalks; the flowers terminate the stalks, growing in long spikes; they are of a light blue, covered toward their hinder part with a mealy down. This flowers in July and August, and in autumn the stalks decay to the root.

The sixth sort grows naturally in Siberia, from whence the seeds were sent to the Imperial garden at Pe-

tersburgh, where they succeeded; and the seeds were sent me from thence by the late Dr. Animan, who was professor of botany in that university. This hath a perennial root; which puts out two or three branching stalks every spring; these rise about a foot and a half high, and are garnished at each joint with leaves composed of many narrow segments, which terminate with several acute points; they are smooth, and of a light green colour; the flowers come out toward the upper part of the stalks singly, each standing upon a long naked foot-stalk; these are large, and of a fine azure colour; they appear the latter part of July, and are succeeded by seeds which ripen in the autumn.

The seventh sort grows naturally in America; this is a perennial plant, which rises with strong branching stalks six or seven feet high, garnished with hand-shaped leaves, which are divided into four or five broad lobes, ending with many acute points; these are smooth, and stand upon long foot-stalks; the flowers terminate the stalks, growing in long spikes; they are of a fine blue colour, with a bearded nectarium, having two lips; and of a dark colour, resembling at a small distance the body of a bee.

All the perennial Larkspurs are propagated by seeds, which, if sown in autumn, will more certainly succeed, than those which are sown in the spring; when the plants come up, they should be kept clean from weeds, and where they are too close together, part of them should be drawn out, to allow room for the others to grow till the following autumn, when they must be planted where they are to remain; the following summer they will flower, and the roots continue many years growing in magnitude, so will produce a greater number of flower-stalks.

The eighth sort is an annual plant, which grows naturally in the Levant, as also in Calabria; this rises with a strong hairy stalk about two feet high, garnished with hand-shaped hairy leaves, composed of five or seven oblong lobes, which have frequently one or two acute indentures on their sides; the flowers form a loose spike at the upper part of the stalk, each standing on a long foot-stalk; the flowers are of a pale blue or purple colour, and have a two-leaved nectarium: this is propagated by seeds, which should be sown in autumn, for those sown in the spring never grow the same year. The seeds should be sown where the plants are to remain, and require no other treatment than the common Larkspur. The common people use the powder of this seed to kill lice, from whence it has been titled Lousewort.

DENS CANIS. See ERYTHRONIUM.

DENS LEONIS. See LEONTODON.

DENTARIA. Lin. Gen. Plant. 726. Tourn. Inst. R. H. 225. tab. 110. Toothwort; in French *Dentaire*.

The CHARACTERS are,

The empalement of the flower is composed of four oblong oval leaves, which fall off; the flower hath four obtuse petals placed in form of a cross; it hath six stamina, four of which are as long as the empalement, the other two are shorter; these are terminated by oblong heart-shaped summits, which stand erect. In the center is situated an oblong germen, supporting a short thick style, crowned by an obtuse stigma; the germen afterward becomes a long taper pod with two cells, divided by an intermediate partition, opening with two valves, including many roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradynamia Siliculosa, the flowers having four long and two short stamina, and the seeds being inclosed in long pods.

The SPECIES are,

1. DENTARIA (*Pentaphyllos*) foliis summis digitatis. Lin. Sp. 912. *Five-leaved Toothwort, whose upper leaves are hand-shaped.* Dentaria pentaphyllos, foliis mollioribus. C. B. P. 322. *Five-leaved Toothwort with soft leaves.*
2. DENTARIA (*Bulbifera*) foliis inferioribus pinnatis, summis simplicibus. Hort. Cliff. 335. *Toothwort with lower-leaves winged, and the upper ones single.* Denta-

ria

ria heptaphyllos baccifera. C. B. P. 322. Seven-leaved bulb-bearing Toothwort.

3. DENTARIA (*Enneaphyllos*) foliis ternis ternatis. Lin. Sp. Plant. 653. *Toothwort with three-leaved trifoliate leaves. Dentaria triphyllos. C. B. P. 322. Three-leaved Toothwort.*

The first sort rises with a strong stalk a foot and a half high, garnished with a leaf at each joint, composed of five lobes, which are four inches long, and near two broad in the widest part, ending in acute points, deeply sawed on their edges; these are smooth, and stand on long foot-stalks; the flowers grow in loose spikes at the top of the stalks; they are small, of a bluish colour, and succeeded by long taper pods filled with small roundish seeds. It grows in the shady woods in the south of France and Italy.

The second sort rises with slender stalks about a foot high; the leaves at the bottom have seven lobes, those a little above five, others but three, and at the upper part of the stalk they are single: the flowers grow in clusters at the top of the stalk; these have four obtuse purple petals, and are succeeded by taper pods filled with roundish seeds.

The third sort rises with an upright stalk a foot high; the leaves are composed of nine lobes, three growing together, so that one leaf has three times three; the flowers grow in small bunches on the top of the stalks, and are succeeded by small taper pods filled with roundish seeds.

These plants grow on the mountains in Italy, and in the woods of Austria. The second sort is found wild in some parts of England, but particularly near Harefield, in moist shady woods, and is seldom preserved in gardens: this produces bulbs on the side of the stalks, where the leaves are set on, which, if planted, will grow and produce plants. These plants are propagated by seeds, or parting their roots; the seeds should be sown in autumn, soon after they are ripe, in a light sandy soil and a shady situation: in the spring the plants may be taken up where they grow too close, and transplanted out in the like soil and situation; where, after they have taken root, they will require no farther care, but to keep them clear from weeds: the second year they will produce flowers, and sometimes perfect their seeds.

The best time to transplant the roots is in October, when they should be planted in a moist soil and a shady situation; for they will not live in a dry soil, or when they are exposed to the sun.

- D E W is by some defined to be a meteor bred of a thin cold vapour, or composed of the steams and vapours of the earth; which, being exhaled by the heat of the sun, and kept suspended during his presence, do, upon his absence, convene into drops, and then fall down unto the earth again.

Others define it, a thin, light, insensible mist or rain, falling while the sun is below the horizon.

The origin and matter of dews are, without doubt, from vapour and exhalations of the earth and water, raised by the warmth of the sun and earth, &c.

There being many vapours in the air, though not always visible, hence it comes to pass, that even in clear weather great dews fall, especially in countries where it seldom rains; for when it happens that the scattered vapours are collected and condensed together, and forced downwards, they must needs fall, and bedew the plants and grass.

The thin vesicles, of which vapours consist, being once detached from their bodies, keep rising in the air till they arrive at such a stage as is of the same specific gravity with themselves, when their rise is stopped: now, as it is the warmth or fire that dilates the parts of water, and forms those vesicles that are specifically lighter than the air, and are capable of ascending therein; so when that heat declines, or is lost, as by the approach or contiguity of any colder body, the vesicles condense, and become heavier and descend.

Therefore the sun warming the atmosphere in the day-time, by the continual influx of his rays, the va-

pours being once raised, continue their progress, not meeting with any thing to increase their gravity, till such time as they are got far beyond the reach of the reflected warmth of the earth in the middle region of the atmosphere, and there condense and form clouds.

Though some say, it is disputable whether dews ever congregate so as to form clouds, as they are only elevated by the sun; so that when that power is gone, as it is after the setting of the sun, they immediately descend; and this is more observable in very warm weather, and very hot climates.

The time for the falling of the dew is either before sun-rising, or after sun-set; that it may regularly fall at such times, it is necessary for the air to be calm, for windy or stormy weather hinders it; but when it is calm weather, and gentle breezes are felt from the west about the setting, and from the east about the rising of the sun, it is probable, that by moderately cooling the air, they collect the vapours and precipitate them; and because the morning breezes are more general than the evening ones, for this reason the evening dews fall only here and there, but those in the morning seldom fail to be universal: or, as it may be otherwise expressed, when the sun is got below the horizon, the atmosphere cools the vapours, which have in the preceding day been raised by the warmth of the earth; and the rays of the sun being lodged there, as soon as they are got out of the air, they begin to condense apace, and spend their stock of heat and fire on the cold moist air that they pass through.

Hence it is, that dews are more copious in the spring than other seasons, there being a greater stock of vapour in readiness, by reason there has been but a small expence thereof during the winter's cold and frost than at other times.

It is found by experience, that the dews are more copious in hotter countries than in cold, as Pliny observes of the summer nights in Africa, which he calls *Roscidæ æstate noctes*; the reason of which seems to be this, that in the day-time the heat of the sun raises abundance of vapours out of the water; which vapours are so extremely rarefied by the same heat, that they are dispersed far and wide; but the cool of the night brings them together, and condenses them to that degree, that they fall to the ground, but not in such large drops as rain does; but in colder countries, where there are frequent rains, and the vapours are less rarefied, most of them come down in rain, and but a small part turns to dew: besides, in Africa there is a great difference between the heat of the day and night, particularly in summer; for their nights are long, and very cold; whereas in northern countries they are little colder than the day, and much shorter than in places nearer the line.

Pliny likewise relates of Egypt, that it abounds in dews throughout all the heat of summer; for the air being there too hot to constipate the vapours in the day-time, they never gather into clouds, and for that reason they have no rain. But it is known, in climates where the days are excessive hot, the nights are remarkably cold, so that the vapours that are raised after sun-set are readily condensed into dews: or, perhaps notable coldness may be rather the effect than the cause of the quantity of dews; for much vapour being raised by the great heat of the earth, and the stock of fire being spent on it in the day-time, the influx of such a great quantity of moisture must greatly chill the air.

The difference between dew and rain seems to be only this, that dew falls at some particular times as aforesaid, and in very small drops, so as to be seen when down, but scarce perceivable while it is falling; whereas rain falls at any time, and in grosser drops.

The reverend Dr. Hales, in his *Treatise of Vegetable Statics*, tells us, That in order to find out the quantity of dew that fell in the night on the 15th of August, 7 p. m. he took two glazed earthen pans, which were three inches deep, and twelve inches diameter

in surface: that he filled them with pretty moist earth, taken off the surface of the ground, and they increased in weight by the night's dew 180 grains; and decreased in weight by the evaporation of the day 1 ounce + 282 grains.

He says likewise, he set these in other broader pans to prevent any moisture from the earth sticking to the bottom of them. He adds, that the moister the earth is, the more dew falls on it in a night, and more than a double quantity of dew falls on a surface of water than there does on an equal surface of moist earth. The evaporation of a surface of water in nine hours winter's dry day, is $\frac{1}{11}$ of an inch: the evaporation of a surface of ice set in the shade during a nine hours day, was $\frac{1}{11}$.

So here are 540 grains more evaporated from the earth every 24 hours in summer than fall in dew in the night; that is, in 21 days near 26 ounces from a circular area of a foot diameter; and circles being as the squares of their diameters, 10 pounds + 2 ounces will in 21 days be evaporated from the hemisphere of 30 inches diameter, which the Sunflower's root occupies; which, with the 29 pounds drawn off by the plant in the same time, makes 39 pounds, that is, 9 pounds and $\frac{3}{4}$ out of every cubic foot of earth, the plant's roots occupying more than 4 cubic feet: but this is a much greater degree of driness than the surface of the earth ever suffers for 15 inches depth, even in the driest seasons in this country.

In a long dry season therefore, especially within the tropics, we must have recourse, for sufficient moisture to keep plants and trees alive, to the moist strata of earth, which lie next below that in which the roots are.

Now moist bodies always communicate of their moisture to more dry adjoining bodies; but this slow motion of the ascent of moisture is much accelerated by the sun's heat to considerable depths in the earth, as is probable, he says, from the twentieth experiment in the said book.

Now 180 grains of dew falling in one night on a circle of a foot diameter = 113 square inches; these 180 grains being equally spread on this surface, its

depth will be $\frac{1}{113}$ part of an inch = $\frac{180}{113 \times 254}$. He adds,

that he found the dew in a winter night to be the $\frac{1}{11}$ part of an inch; so that if we allow 151 nights for the extent of the summer dew, it will in that time arise to one inch depth: and reckoning the remaining 214 nights for the extent of the winter's dew, it will produce 2,39 inches depth, which makes the dew of the whole year amount to 3,39 inches depth.

And the quantity which evaporated in a fair summer's day from the same surface, being as 1 ounce 282 grains, gives $\frac{1}{11}$ part of an inch depth for evaporation, which is four times as much as fell at night.

He says likewise, that he found by the same means, the evaporation of a winter's day to be nearly the same as in a summer's day; for the earth being in winter more saturate with moisture, that excess of moisture answers to the excessive heat in summer.

Nic. Cruquius, N° 381, of the Philosophical Transactions, found, that 28 inches depth evaporated in a whole year from water, i. e. $\frac{1}{11}$ of an inch each day at a mean rate: but the earth in a summer's day evaporates $\frac{1}{11}$ of an inch, so the evaporation of a surface of water is to the evaporation of a surface of earth in summer as 10 : 3.

The quantity of rain and dew that falls in a year is at a medium 22 inches. The quantity of the earth's evaporation in a year is at least 9 + $\frac{1}{2}$ inches; since that is the rate at which it evaporates in a summer's day: from which 9 + $\frac{1}{2}$ inches are to be deducted 3,39 inches for circulating daily dew, there remains 6,2 inches; which 6,2 inches deducted from the quantity of rain that falls in a year, there remains at least 16 inches depth to replenish the earth with moisture for vegetation, and to supply the springs and rivers.

Dr. Hales proceeds to instance, in the case of a Hop-ground which he gives in the ninth experiment of his book of Vegetable Statics, that the evaporation there found, from the Hops, considered only for three months, at $\frac{1}{10}$ part of an inch each day, which will be $\frac{3}{10}$ of an inch: but before it be allowed 6,2 inches to form the surface of the ground, which added to the $\frac{3}{10}$ give 7,1 inches, which is the utmost that can be evaporated from a surface of Hop-ground in a year; so that of 22 inches depth of rain, there remain 15 inches to supply springs, which are more or less exhausted, according to the driness or wetness of the year.

Hence we find, that 22 inches depth of rain in a year is sufficient for all the purposes of nature in such flat countries as that about Teddington near Hampton Court. But in the hill countries, as in Lancashire, there falls 42 inches depth of rain water, from which, deducting 7 inches for evaporation, there remains 35 inches depth of water for the springs, besides great supplies from much more plentiful dews than fall in plain countries; which vast stores seem so abundantly sufficient to answer the great quantity of water, which is conveyed away by the springs and rivers from those hills, that we need not have recourse for supplies to the great abyss, whose surface at high water is surmounted some hundreds of feet by those vast hills from whence the longest and greatest rivers take their rise.

DIANTHERA. Lin. Gen. Plant. 37. Flor. Virg. 6.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubulous, and cut at the top into five equal parts; the flower is of the grinning kind, having one petal. with a short tube; the upper lip is reflexed and bifid, the lower is divided into three parts, the middle being the broadest; it hath two short slender stamina adhering to the back of the petal, one of these hath a twin summit, the other is a little taller. It hath an oblong germen, supporting a slender style the length of the stamina, crowned by an obtuse stigma. The empalement afterward becomes a capsule with two cells, opening with two valves, which are alternately compressed at the top and bottom, and open with an elasticity, casting a single flat seed out of each cell.

This genus of plants is ranged in the first section of Linnæus's second class, intitled Diandria Monogynia, the flower having two stamina and one style. This is one of the genera which, by Linnæus's method, is separated to a great distance from their congeners; for by all their other characters they should be joined to his fourteenth class, but having only two stamina, they are put under his second.

We know but one SPECIES of this genus at present, viz.

DIANTHERA (*Americana*) spicis solitariis alternis. Lin. Sp. 24. *Dianthera with solitary alternate spikes.*

This plant grows naturally in Virginia, and other parts of North America, from whence the seeds have been sent to England, where they have succeeded. This is a low herbaceous plant with a perennial root, which sends out several weak stalks about four inches long, garnished with roundish leaves of an aromatic odour, standing close to the stalks; they are hairy, and of a dark green colour; from the side of the stalks the flowers are produced in small spikes, placed alternately; these are in shape and colour very like those of the Clinopodium, but have only two stamina in each. It flowers the latter end of July, but rarely produces seeds in England.

This plant is very difficult to preserve in this country, for although it is hardy enough to live in the open air in England, yet it is very subject to rot in winter; and if it is placed under shelter, it is apt to draw up weak, and soon after decay, so that at present the plants are rare in this country.

DIANTHUS. Lin. Gen. Plant. 500. Caryophyllus. Tourn. Inst. R. H. 329. Clove Gilly Flower, Carnation Pink; in French, *Ocillet*.

The CHARACTERS are,

The flower hath a long cylindrical empalement which is permanent; it hath five petals, whose tails are as long as the empalement, but their upper part is broad, plain, and crenated on their borders; these are inserted in the bottom of the tube, and spread open above. It hath ten stamina which are as long as the empalement, terminated by oblong compressed summits. In the center is situated an oval germen, supporting two styles which are longer than the stamina, crowned by recurved stigmas. The germen afterward becomes a cylindrical capsule with one cell, opening in four parts at the top, and filled with compressed angular seeds.

This genus of plants is ranged in the second section of Linnæus's tenth class, intitled Decandria Digynia, the flowers having ten stamina and two styles.

The SPECIES are,

1. DIANTHUS (*Deltoides*) floribus solitariis, squamis calycinis lanceolatis binis, corollis crenatis. Hort. Cliff. 164. *Dianthus* with a single flower having a double scaly empalement, and crenated petals. Caryophyllus sylvestris vulgaris latifolius. C. B. P. 209. *Maiden Pink*.
2. DIANTHUS (*Virgineus*) caule subunifloro, corollis crenatis, squamis calycinis brevissimis, foliis subulatis. Lin. Sp. Plant. 412. *Dianthus* with one flower on a stalk, crenated petals, very short scales to the empalement, and awl-shaped leaves. Caryophyllus minor repens. Nostras. Raii. Syn. 335. *English small creeping Pink*, commonly called the matted Pink by seedsmen.
3. DIANTHUS (*Glaucus*) floribus subsolitariis, squamis calycinis lanceolatis quaternis, corollis crenatis. Hort. Cliff. 164. *Dianthus* with one flower on a stalk, having four spear-shaped scales to the empalement, and crenated petals. Tunica ramosior flore candido cum corollâ purpureâ. Hort. Elth. 400. *Branching Pink* with a white flower, having a purple circle, commonly called *Mountain Pink*.
4. DIANTHUS (*Plumarius*) floribus solitariis, squamis calycinis subovatis brevissimis, corollis multifidis fauce pubescentibus. Lin. Sp. Plant. 411. *Dianthus* with a single flower, having short oval scales to the empalement, and petals cut into many points, with a hairy bottom. Caryophyllus simplex flore minore pallido rubente. C. B. P. 208. *Single wild Pink*, with a small, pale, reddish flower.
5. DIANTHUS (*Caryophyllus*) floribus solitariis squamis calycinis subovatis brevissimis, corollis crenatis. Hort. Cliff. 164. *Dianthus* with a single flower, having short oval scales to the empalement, and crenated petals. Caryophyllus hortensis simplex, flore majore. C. B. P. 208. *Single Garden Carnation* with a large flower.
6. DIANTHUS (*Armeria*) floribus aggregatis fasciculatis, squamis calycinis lanceolatis villosis tubum æquantibus. Hort. Cliff. 165. *Dianthus* with many flowers gathered into bunches, having hairy spear-shaped scales to the empalement, as long as the tube of the flower. Caryophyllus barbatus sylvestris. C. B. P. 208. *Bearded wild Pink*, called *Deptford Pink*.
7. DIANTHUS (*Barbatus*) floribus aggregatis fasciculatis, squamis calycinis linearibus, foliis lanceolatis. *Dianthus* with many flowers gathered in bunches, having very narrow scales to the empalement, and spear-shaped leaves. Caryophyllus barbatus hortensis latifolius. C. B. P. 208. *Broad-leaved Garden Sweet William*.
8. DIANTHUS (*Prolifer*) floribus aggregatis capitatis, squamis calycinis ovatis obtusis muticis tubum superantibus. Lin. Sp. Plant. 587. *Dianthus* with flowers collected into heads, and obtuse, oval, chaffy scales to the empalements, which are longer than the tube. Caryophyllus sylvestris prolifer. C. B. P. 209. *Wild childing Sweet William*.
9. DIANTHUS (*Ferrugineis*) floribus aggregatis capitatis, squamis calycinis lanceolatis aristatis, corollis crenatis. *Dianthus* with flowers collected in heads, having spear-shaped scales to the empalement which are bearded, and crenated petals. Caryophyllus montanus umbellatus, floribus variis luteis ferrugineis Italicus. Barrel. Obs. 648. *Italian umbellated Mountain Pink*, with flowers varying from yellow to an iron colour.
10. DIANTHUS (*Cbinensis*) floribus solitariis, squamis ca-

lycinis subulatis patulis, tubum æquantibus, corollis crenatis. Hort. Cliff. 164. *Dianthus* with a single flower on each stalk, awl-shaped spreading scales to the empalement equalling the tube, and crenated petals. Caryophyllus sinensis supinus, leucos folio, flore unico. Fourn. Act. Par. 1705. *The China Pink*.

11. DIANTHUS (*Arenarius*) caulibus unifloris squamis calycinis ovatis obtusis, corollis multifidis, foliis linearibus. Flor. Suec. 318. *Dianthus* having a single flower upon a stalk, oval scales to the empalement, the petals of which are cut into many points, and narrow leaves. Caryophyllus sylvestris humilis, flore unico. C. B. P. 209. *Dwarf wild Pink* with one flower.
 12. DIANTHUS (*Alpinus*) caule unifloro, corollis crenatis, squamis calycinis exterioribus tubum æquantibus, foliis linearibus obtusis. Lin. Sp. Plant. 412. *Dianthus* with one flower having crenated petals, the outer scales of the empalement equalling the tube, and narrow obtuse leaves. Caryophyllus pumilus latifolius. C. B. P. 209. *Dwarf broad-leaved Pink*.
 13. DIANTHUS (*Superbus*) floribus paniculatis, squamis calycinis brevibus acuminatis, corollis multifido-capillaribus, caule erecto. Amoen. Acad. 4. p. 272. *Dianthus* with paniculated flowers, having short-pointed scales to their empalement, multifid petals, and an upright stalk.
 14. DIANTHUS (*Diminutus*) floribus solitariis, squamis calycinis octonis florem superantibus. Lin. Sp. 587. *Dianthus* with a single flower on each stalk, having eight scales which rise above the petals of the flower. Caryophyllus sylvestris minimus. Tabern. Hist. 290.
- The first sort hath creeping stalks, from which come out several tufted heads, closely garnished with narrow leaves, whose base lie over each other embracing the stalks; between these arise the flower-stalks, which grow about six inches high, garnished at every joint by two narrow grassy leaves placed opposite. The stalks are terminated by a single flower. It flowers in June and July, and the seeds ripen in autumn. This is rarely admitted into gardens, the flower having no beauty.
- The second sort is a low trailing plant, whose stalks lie on the ground; these grow very close together, and are garnished with short, narrow, grassy leaves of a deep green colour; the stalks are terminated by small red flowers, each standing upon a separate footstalk. It flowers in July, and the seeds ripen in September. This sort grows naturally in several parts of England, so is not often cultivated in gardens at present; but formerly the seeds were sown to make edgings for the borders of the flower-garden by the title of matted Pink, by which the seeds were sold in the shops.
- The third sort grows naturally upon Chidder rocks in Somersetshire, and some other parts of England. This was formerly cultivated in the gardens by the title of Mountain Pink. It hath a resemblance of the second sort, but the leaves are shorter, and of a grayish colour; the stalks grow taller, and branch more; the flowers are larger, of a white colour, with a purple circle in the bottom, like that sort of Pink called Pheasants Eye. As the flowers of this sort have no scent, the plants are seldom kept in gardens.
- The fourth sort grows naturally in several parts of England, frequently upon old walls; it is a small single Pink, of a pale red colour, so is not cultivated in gardens.
- The fifth sort is a small single Carnation, which has been long cast out of all the gardens; from one of this sort it is supposed, many of the fine flowers now cultivated in the gardens have been raised.
- The sixth sort grows naturally in several parts of England, and particularly in a meadow near Deptford in Kent, from whence it had the title of Deptford Pink. This is of the kind called Sweet William; the flowers of these grow in clusters at the end of the branches; they are red, and have long bearded empalements. I have cultivated this sort above forty years, and have never observed it to vary.

The

The seventh sort is the common Sweet William, which has been long cultivated in the gardens for ornament, of which there are now great varieties which differ in the form and colour of their flowers, as also in the size and shape of their leaves; those which have narrow leaves were formerly titled Sweet Johns by the gardeners, and those with broad leaves were called Sweet Williams; there are some of both these sorts with double flowers, which are very ornamental plants in gardens.

The eighth sort grows naturally in the south of France, in Spain, Italy, and in England. This is an annual plant, which rises with an upright stalk about a foot high, garnished with narrow grassy leaves, and is terminated by a small head or cluster of pale red flowers, which are included in one common scaly empalement. These have little beauty, so the plants are seldom kept in gardens.

The ninth sort is a biennial plant, which rises with an upright stalk a foot and a half high, having two long narrow leaves placed opposite at each joint, which embrace the stalk with their base; they are of a deep green colour, stiff, and end in acute points. The flowers grow in close clusters at the top of the stalks, having stiff bearded empalements; they are yellow and iron coloured intermixed on the same stalk, and frequently they are of both colours in the same head. This plant flowers in July, and the seeds ripen in autumn.

The tenth sort came originally from China, so it is titled the China Pink; the flowers of this have no scent, but there are a great variety of lively colours among them; and of late years there has been great improvements made in the double flowers of this sort, some of which are as full of petals as the double Pink, and their colours are very rich. The plants seldom grow more than eight or nine inches high, branching out on every side; the branches grow erect, and are terminated each by a single flower. These flower in July, and continue in succession till the frost stops them; they are commonly raised every year from seeds, but the roots will continue two years in dry ground.

The eleventh sort is found growing naturally upon old walls and buildings in many parts of England; this is a single small Pink, of a sweet odour, but of a pale colour and small, so makes no appearance; and since the great improvement which has been made in these flowers by culture, this has been entirely neglected.

The twelfth sort grows naturally on the Alps. This hath round, short, bluish leaves; the stalks seldom rise more than four inches high, each being terminated by a single flower of a pale red colour. It is sometimes preserved in botanic gardens for the sake of variety, but is rarely admitted into other gardens.

The thirteenth sort grows naturally in Germany and Denmark; the leaves of this sort are like those of the narrow-leaved Sweet William; the stalk rises more than a foot high, and is terminated by a single flower, having five large petals of a pale red colour, which are cut into many long segments. The roots of this sort will live three or four years, but the second year from seeds they are in greatest beauty; therefore as the seeds ripen well in England, young plants should be annually raised.

The fourteenth sort is a very diminutive plant, having short narrow leaves growing in close heads; the stalk seldom rises six inches high, which is terminated by a single flower, of a pale red colour, so has little beauty, therefore is only kept in botanic gardens for variety.

The sorts here enumerated, are such as the botanists allow to be distinct species; and all the varieties of fine flowers, which are now cultivated in the gardens of the curious, are only accidental variations which have been produced by culture; and the number of these are greatly increased annually, in many different parts of Europe; so that as new varieties are obtained, the old flowers are rejected.

The plants of this genus may be properly enough divided into three sections: The first to include all the variety of Pinks, the second all the Carnations, and the third those of the Sweet William; for although these agree so nearly in their principal characters, as to be included under the same genus by the botanists, yet they never vary from one to the other, though they frequently change and vary in the colour of their flowers.

I shall now proceed to treat of these under their different sections, and first I shall begin with the Pink, of which there are a great variety now cultivated in the gardens; the principal of which are, the damask Pink, the white Shock, the Pheasant Eye, with double and single flowers, varying greatly in their size and colour; the common red Pink, Cob's Pink, Dobson's Pink, white Cob Pink, and Bar's Pink. The old Man's Head, and painted Lady Pink, rather belong to the Carnation.

The damask Pink is the first of the double sorts in flower. This hath but a short stalk; the flower is not very large, and not so double as many others; the colour is of a pale purple, inclining to red, but is very sweet.

The next which flowers is the white Shock, which was so called from the whiteness of its flowers, and the borders of the petals being much jagged and fringed; the scent of this is not so agreeable as of some others.

Then comes all the different kinds of Pheasants Eye, of which there are frequently new varieties raised, which are either titled from the persons who raised them, or the place where they were raised; some of these have very large double flowers, but those which burst their pods are not so generally esteemed.

The Cob Pink comes after these to flower; the stalks of this are much taller than those of any of the former; the flowers are very double, and of a bright red colour; these have the most agreeable odour of all the sorts, so merits a place in every good garden. The time of the Pinks flowering is from the latter end of May to the middle of July, and frequently that sort of Pheasant Eye, which is called Bar's Pink, will flower again in autumn.

The old Man's Head Pink, and the painted Lady, do not flower till July, coming at the same season with the Carnation, to which they are more nearly allied than the Pink. The first when it is in its proper colours, is purple and white striped and spotted, but this frequently is of one plain colour which is purple; this sort will continue flowering till the frost in autumn puts a stop to it, and the flowers having an agreeable scent, renders them valuable. The painted Lady is chiefly admired for the liveliness of its colour, for it is not so sweet, or of so long continuance as the other.

The common Pinks are propagated either by seeds, which is the way to obtain new varieties, or by making layers of them, as is practised for Carnations; or by planting slips, which, if carefully managed, will take root very well.

If they are propagated by seeds, there should be care taken in the choice of them, and only the seeds of the best sorts saved, where the persons are curious to have the finest flowers. These seeds may be sown in the spring, and the plants afterward treated in the same manner as is hereafter directed for the Carnation; with this difference only, that as the Pinks are less tender, they may be more hardily treated. Those which are propagated by layers, must be also managed as the Carnation, for which there are full instructions hereafter given. The old Man's Head and painted Lady Pinks, are commonly propagated this way, but most of the other sorts are propagated from slips.

The best time to plant the slips of Pinks is about end of July, when, if there should happen rain, it will be of great service to them; but if the weather should prove dry, they will require to be watered every other day, until they have taken root; these should

should be planted in a shady border, and the ground should be dug well, and all the clods broken, and if no rain falls, it should be well soaked with water a few hours before the slips are planted; then the slips should be taken from the plants, and all their lower leaves stripped off, and planted as soon as possible after, for if they are suffered to lie long after they are taken from the plants, they will wither and spoil; these need not be planted at a greater distance than three inches square, and the ground must be closed very hard about them; then they must be well watered, and this must be repeated as often as is found necessary, till the cuttings have taken root; after which they will require no other care but to keep them clean from weeds till autumn, when they should be transplanted to the borders of the flower-garden where they are to remain. There are some who plant the slips of Pinks later in the season than is here directed; but those plants are never so strong nor flower so well, as those which are early planted.

We shall next proceed to the culture of the Carnation; these the florists distinguish into four classes. The first they call Flakes; these are of two colours only, and their stripes are large, going quite through the leaves.

The second are called Bizarres; these have flowers striped or variegated with three or four different colours, in irregular spots and stripes.

The third are called Piquettes; these flowers have always a white ground, and are spotted (or pounced, as they call it) with scarlet, red, purple, or other colours.

The fourth are called painted Ladies; these have their petals of a red or purple colour on the upper side, and are white underneath.

Of each of these classes there are numerous varieties, but chiefly of the Piquettes, which some years ago were chiefly in esteem with the florists, but of late years the Flakes have been in greater request than any of the other kinds. To enumerate the varieties of the chief flowers in any one of these classes, would be needless, since every country produces new flowers almost every year; so that those flowers, which, at their first raising, were greatly valued, are in two or three years become so common, as to be of little worth, especially if they are defective in any one property. Therefore (where flowers are so liable to mutability, either from the fancy of the owner, or that better kinds are yearly produced from seeds, which, with good florists, always take place of older or worse flowers, which are turned out of the garden to make room for them) it would be but superfluous in this place to give a list of their names, which are generally borrowed either from the names and titles of noblemen, or from the person's name, or place of abode, who raised it.

These flowers are propagated either from seeds (by which new flowers are obtained), or from layers, for the increase of those sorts which are worthy maintaining; but I shall first lay down the method of propagating them from seeds, which is thus:

Having obtained some good seeds, either of your own saving, or from a friend that you can confide in, about the middle of April, prepare some pots or boxes (according to the quantity of seed you have to sow); these should be filled with fresh light earth mixed with rotten neat's dung, which should be well incorporated together; then sow your seeds thereon (but not too thick) covering it about a quarter of an inch with the same light earth, placing the pots or cases so as to receive the morning sun only till eleven of the clock, observing also to refresh the earth with water as often as it may require. In about a month's time your plants will come up, and if kept clear from weeds, and duly watered, will be fit to transplant about the latter end of July; at which time you should prepare some beds (of the same sort of earth as was directed to sow them in) in an open airy situation; in which you should plant them at about three inches square, observing to water and shade them till they have taken

new root, then you must observe to keep them clear from weeds; in these beds they may remain until the end of August, by which time they will have grown so large as almost to meet each other; then prepare some more beds of the like good earth (in quantity proportionable to the flowers you have raised) in which you should plant them at six inches distance each way, and not above four rows in each bed, for the more conveniently laying such of them as may prove worthy preserving, for in these beds they should remain to flower.

The alleys between these beds should be two feet wide, that you may pass between the beds to weed and clean them. If the season should prove very dry at this time, they should not be transplanted till there is some rain; so that it may happen to be the middle, or latter end of September some years, before there may be wet enough to moisten the ground for this purpose; but if there is time enough for the plants to get good root before the frost comes on, it will be sufficient. If the winter should prove severe, the beds should be arched over with hoops, that they may be covered with mats, otherwise many of the plants may be destroyed, for the good flowers are not so hardy as the ordinary ones of this genus. There will be no other culture wanting to these, but to keep them clean from weeds, and when they shoot up their stalks to flower, they must be supported by sticks to prevent their breaking. When your flowers begin to blow, you must look over them to see which of them proffer to make good flowers, which as soon as you discover, you should lay down all the layers upon them; those which are well marked, and blow whole without breaking their pods, should be reserved to plant in borders, to furnish you with seed; and those which burst their pods, and seem to have good properties, should be planted in pots, to try what their flowers will be, when managed according to art; and it is not till the second year that you can pronounce what the value of a flower will be, which is in proportion to the goodness of its properties; but, that you may be well acquainted with what the florists call good properties, I shall here set them down.

1. The stem of the flower should be strong, and able to support the weight of the flower without hanging down.

2. The petals (or leaves) of the flower should be long, broad, and stiff, and pretty easy to expand, or (as the florists term them) should be free flowers.

3. The middle pod of the flower should not advance too high above the other petals of the flower.

4. The colours should be bright, and equally marked all over the flower.

5. The flower should be very full of leaves, so as to render it, when blown, very thick and high in the middle, and the outside perfectly round.

Having made choice of such of your flowers as promise well for the large sort, these you should mark separately for pots, and the round whole blowing flowers for borders; you should pull up all single flowers, or such as are ill-coloured, and not worth preserving, that your good flowers may have the more air and room to grow strong; these having been laid at a proper season, as soon as they have taken root (which will be some time in August) they should be taken off, and planted out, those that blow large, in pots, and the other in borders (as hath been already directed).

Of late years the whole-blowing flowers have been much more esteemed than those large flowers which burst their pods, but especially those round flowers which have broad stripes of beautiful colours, and round Rose leaves, of which kinds there have been a great variety introduced from France within these few years; but as these French flowers are extremely apt to degenerate to plain colours, and being much tenderer than those which are brought up in England, there are not such great prices given for the plants now, as have been a few years past; from the present taste for these whole-blowing Flake flowers, many

of the old varieties, which had been turned out of the gardens of the florists many years ago, to make room for the large flowers, which were then in fashion, have been received again; and large prices have been paid of late for such flowers as some years ago were sold for one shilling a dozen, or less, which is a strong proof of the variableness of the fancies of the florists.

But I shall now proceed to give some directions for propagating these flowers by layers, and the necessary care to be taken in order to blow them fair and large.

The best season for laying these flowers is in June, as soon as the shoots are strong enough for that purpose, which is performed in the following manner: after having stripped off the leaves from the lower part of the shoot intended to be laid, make choice of a strong joint about the middle part of the shoot (not too near the heart of the shoot, nor in the hard part next the old plant); then with your penknife make a slit in the middle of the shoot from the joint upwards half way to the other joint, or more, according to their distance; then with your knife cut the tops of the leaves, and also cut off the swelling part of the joint where the slit is made, so that the part slit may be shaped like a tongue; for if that outward skin is left on, it would prevent their pushing out roots; then having loosened the earth round the plant, and, if need be, raised it with fresh mould, that it may be level with the shoot intended to be laid down, lest by the ground being too low, by forcing down the shoot you split it off; then with your finger make a hollow place in the earth, just where the shoot is to come, and with your thumb and finger bend the shoot gently into the earth, observing to keep the top as upright as possible, that the slit may be open; and being provided with forked sticks for that purpose, thrust one of them into the ground, so that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the shank of the layer with the same sort of earth, giving it a gentle watering to settle the earth about it, observing to repeat the same as often as is necessary, in order to promote their rooting. In about five or six weeks after this, the layers will have taken root sufficient to be transplanted; against which time you should be provided with proper earth for them, which may be composed after the following manner:

Make choice of some good up-land pasture, or a common that is of a hazel earth, or light sandy loam; dig from the surface of this your earth about eight inches deep, taking all the turf with it; let this be laid in a heap to rot and mellow for one year, turning it once a month, that it may sweeten; then mix about a third part of rotten neats dung, or for want of that, some rotten dung from a Cucumber or Melon-bed; let this be well mixed together, and if you can get it time enough before-hand, let them lie mixed six or eight months before it is used, turning it several times, the better to incorporate their parts.

Observe, that although I have mentioned this mixture as the best for these flowers, yet you must not expect to blow your flowers every year equally large in the same composition; therefore some people who are extremely fond of having their flowers succeed well, alter their compositions every year in this manner, viz. one year they mix the fresh earth with neats dung, which is cold; the next year with rotten horse dung, which is of a warmer nature, adding thereto some white sea sand to make the earth lighter.

But, for my part, I should rather advise the planting two or three layers of each of the best kinds in a bed of fresh earth not over dunged, which plants should only be suffered to shew their flowers, that you may be sure they are right in their kind and colours; and when you are satisfied in that particular, cut off the flower-stems, and do not suffer them to spend the roots in blowing, by which means you will strengthen your layers. And it is from these beds I would make

choice of some of the best plants for the next year's blowing, always observing to have a succession of them yearly, by which means you may have every year fine flowers; provided the season proves favourable: for it is not reasonable to suppose, that the layers taken from such roots as have been exhausted in producing large flowers, and have been forced by art to the utmost of their natural strength, should be able to produce flowers equally as large as their mother root did the year before, or as such layers as are fresh from a poorer soil, and in greater health can do. But this being premised, let us proceed to the planting of these layers, which (as I said before) should be done in August, or the beginning of September.

The common method used by most florists is, to plant their layers at this season, two in each pot (the size of which pots are about nine inches over in the clear at the top); in these pots they are to remain for bloom; and therefore, in the spring of the year, they take off as much of the earth from the surface of the pots as they can, without disturbing their roots, filling the pots up again with the same good fresh earth as the pots were before filled with. But there is some difficulty in sheltering a great quantity of these flowers in winter, when they are planted in such large pots, which in most winters they will require, more or less; my method therefore is, to put them singly into halfpenny pots in autumn, and in the middle or latter end of October, to set these pots into a bed of old tanners bark, which has lost its heat, and cover them with a common frame (such as is used for raising Cucumbers and Melons); and in two of these frames, which contain six lights, may be set a hundred and fifty of these pots: in these frames you may give them as much free air as you please, by taking off the lights every day when the weather is mild, and putting them on only in bad weather and great rains; and if the winter should prove severe, it is only the covering the glasses with mats, straw, or Pease-haulm, so as to keep out the frost, which will effectually preserve your plants in the utmost vigour.

In the middle or latter end of February, if the season is good, you must transplant these layers into pots for their bloom (the size of which should be about eight inches over at the top in the clear); in the doing of which, observe to put some potsherds or oyster-shells over the holes in the bottoms of the pots, to keep the earth from stopping them, which would detain the water in the pots to the great prejudice of the flowers: then fill these pots about half way with the same good compost as was before directed, and shake the plants out of the small pots with all the earth about the roots; then with your hands take off some of the earth round the outside of the ball, and from the surface taking off the fibres of the roots on the outside of the ball of earth; then put one good plant exactly in the middle of each pot, so that it may stand well as to the height, i. e. not so low as to bury the leaves of the plant with earth, nor so high, that the shank may be above the rim of the pot; then fill the pot up with the earth before-mentioned, closing it gently to the plant with your hands, giving it a little water, if the weather is dry, to settle the earth about it; then place these pots in a situation where they may be defended from the north wind, observing to give them gentle waterings, as the season may require.

In this place they may remain till the middle or latter end of April, when you should prepare a stage of boards to set the pots upon, which should be so ordered as to have little cisterns of water round each post, to prevent the insects from getting to your flowers in their bloom, which, if they are suffered to do, will mar all your labour, by destroying all your flowers in a short time; the chief and most mischievous insect in this case is, the earwig, which will gnaw off all the lower parts of the petals of the flowers (which are very sweet) and thereby cause the whole flower to fall to pieces; but since the making one of these stages is somewhat expensive, and not very easy to be understood

derstood by such as have never seen them, I shall describe a very simple one, which I have used for several years, which answers the purpose full as well as the best and most expensive one can do: first, prepare some common flat pans, about fourteen or sixteen inches over, and three inches deep; place these two and two opposite to each other, at about two feet distance, and at every eight feet lengthways, two of these pans; in each of these whelm a flower-pot, which should be about six inches over at the top, upside-down, and lay a flat piece of timber, about two feet and a half long, and three inches thick, cross from pot to pot, till you have finished the whole length of your stage; then lay your planks lengthways upon these timbers, which will hold two rows of planks for the size pots which were ordered for the Carnations; and when you have set your pots upon the stage, fill the flat pans with water, always observing, as it decreases in the pans, to replenish it, which will effectually guard your flowers against insects; for they do not care to swim over water, so that if by this, or any other contrivance, the passage from the ground to the stage, on which the pots are placed, is defended by a surface of water three or four inches broad, and as much in depth, it will effectually prevent these vermin from getting to the flowers.

This stage should be placed in a situation open to the south-east, but defended from the west winds, to which these stages must not be exposed, lest the pots should be blown down by the violence of that wind, which is often very troublesome at the season when these flowers blow; indeed they should be defended by trees at some distance, from the winds of every point; but these trees should not be too near the stage, nor by any means place them near walls, or tall buildings, for in such situations the stems of the flowers will draw up too weak. About this time, viz. the middle of April, your layers will begin to shoot up for flower; you must therefore be provided with some square deal sticks, about four feet and a half long, which should be thicker toward the bottom, and planed off taper at the top; these sticks should be carefully stuck into the pots as near as possible to the plant, without injuring it; then with a slender piece of bass mat, fasten the spindle to the stick to prevent its being broken; this you must often repeat, as the spindle advances in height, and also observe to pull off all side spindles as they are produced, and never let more than two spindles remain upon one root, nor above one, if you intend to blow exceeding large. Toward the beginning of June your flowers will have attained their greatest height, and their pods will begin to swell, and some of the earliest begin to open on one side; you must therefore observe to let it open in two other places at equal angles; this must be done so soon as you perceive the pod break, otherwise your flower will run out on one side, and be in a short time past recovering, so as to make a complete flower, and in a few days after the flowers begin to open, you must cover them with glasses which are made for that purpose, in the following manner:

Upon the top of the glass, exactly in the center, is a tin collar, or socket, about three fourths of an inch square, for the flower-stick to come through; to this socket are soldered eight slips of lead at equal distances, which are about six inches and a half long, and spread open at the bottom about four inches asunder; into these slips of lead are fastened slips of glass, cut according to the distances of the lead, which, when they are fixed in, are bordered round the bottom with another slip of lead quite round, so that the glass hath eight angles, with the socket in the middle, and spread open at the bottom about eleven inches wide.

When your flowers are open enough to cover with these glasses, you must make a hole through your flower-stick, exactly to the height of the under part of the pod, through which you should put a piece of small wire about six inches long, making a ring at

one end of the wire to contain the pod, into which ring you should fix the stem of the flower; then cut off all the tyings of bass, and thrust the stem of the flower so far from the stick, as may give convenient room for the flower to expand without pressing against the stick; to which distance you may fix it, by turning your wire so as not to draw back through the hole; then make another hole through the stick, at a convenient distance above the flower, through which you should put a piece of wire, an inch and a half long, which is to support the glasses from sliding down upon the flowers; and be sure to observe, that the glasses are not placed so high as to admit the sun and rain under them to the flowers, nor so low as to scorch their leaves with the heat. At this time also, or a few days after, as you shall judge necessary, you should cut some stiff paper, cards, or some such thing, into collars about four inches over, and exactly round, cutting a hole in the middle of it about three fourths of an inch diameter, for the bottom of the flower to be let through; then place these collars about them, to support the petals of the flower from hanging down; this collar should be placed with inside the calyx of the flower, and should be supported thereby; then observe from day to day what progress your flowers make; and if one side comes out faster than the other, you should turn the pot about, and shift the other side towards the sun; and also if the weather proves very hot, you should shade the glasses in the heat of the day with Cabbage leaves, &c. to prevent their being scorched, or forced out too soon; and when the middle pod begins to rise, you should take out the calyx thereof with a pair of nippers made for that purpose; but this should not be done too soon, lest the middle part of the flower should advance too high above the sides, which will greatly diminish the beauty of it: and you should also observe whether there are more leaves in the flower, than can properly be expanded for want of room; in which case you should put out some of the lowermost or most unlikely leaves to spread, drawing out and expanding the others at the same time: and when your flowers are fully blown, if you cut them off, you should put on a fresh collar of stiff paper, which should be cut exactly to the size of the flower, that it may support the petals to their full width, but not to be seen wider than the flower in any part: when this is put on, you must draw out the widest leaves to form the outside of the flower, which although they should be in the middle (as it often happens,) yet by removing the other leaves they may be drawn down, and so the next longest leaves upon them again, that the whole flower may appear equally globular without any hollow parts. In the doing of this, some florists are so curious as to render an indifferent flower very handsome; and on this depends, in a great measure, the skill of the artist to produce large fine flowers.

During the flowering season, particular care should be taken not to let them suffer for want of water, which should by no means be raw spring water; nor do I approve of compound waters, such as are enriched with various sorts of dung; but the best and most natural water is that of a fine soft river; next to that is pond water, or standing water; but if you have no other than spring water, it should be exposed to the sun and air two days before it is used, otherwise it will give the flowers the canker and spoil them.

The directions here given are chiefly for the management of those large Carnations, which require the greatest skill of the florists, to have them in perfection; but as of late years these have not been so much in esteem as formerly, and those flowers which do not break their pods, and are termed whole Blowers; have now the preference. These are generally planted in pots, and treated in the same way as the large flowers, but do not require so much trouble to blow them: all that is necessary to be done for these, is to fasten their stems up to flower-sticks to prevent their

being

being broken, and to take off the pods which proceed from the side of the stalks, leaving only the top bud to flower, if they are intended to be large and fair; and when the flowers begin to open, if they are screened from the sun in the heat of the day, and also from wet, they will continue much longer in beauty.

But although the most valuable of these flowers are usually planted in pots, and thus carefully treated, yet many of these whole blowing flowers may be planted in beds, or borders of the flower-garden; where they are some of the principal ornaments during their continuance in flower, which is from the beginning of July till the middle of August, especially if the several colours are properly intermixed; for the Flakes and Bizarrs should be intermixed with the Picquettes, and not planted separate, unless where they are designed for saving the seeds; in which case, those which are the finest of each sort, should be planted in beds at a distance from each other, especially where persons are desirous to keep them distinct; for where the sorts are blended together, there will be an admixture of their farina, so that the seeds will vary, and not produce the particular kinds; though I do not remember ever to have seen any Flake flowers arise from seeds of the Picquettes, nor vice versa.

The flowers which are planted in the full ground, generally produce seeds better than those in pots; but whoever proposes to raise a supply of new flowers from seeds, must always observe to save the best of their seedling flowers for this purpose; for it is well known, that after any of these flowers have been a few years propagated by layers, they become barren, and do not seed; which is also the case with most other plants which are propagated by slips, layers, or cuttings; so that the young plants which have been newly obtained from seeds, are always the most productive of seeds: the plants which are propagated by layers or slips, will always continue to produce the same flowers, so that when a fine variety is obtained, it is this way propagated and maintained; but all the new varieties come from seeds, so that all those who are curious in these flowers, annually sow their seeds. I shall next proceed to the culture of that species, which is commonly known by the title of Sweet William; of this there are a great variety of different colours, which are single, and three or four with double flowers: some of these have narrow leaves, which were formerly titled Sweet Johnis, but of late that distinction has not been made, because they are found to vary when raised from seeds.

Some of the single flowers have very rich colours, which frequently vary in those of the same bunch; there are others with fine variegated flowers, and others whose middles are of a soft red, bordered with white, which are called Painted Ladies; but where persons are desirous to preserve any of these varieties in perfection, the best flowers of each should be particularly marked, and no other permitted to stand near them, lest their farina should impregnate them, which would cause them to vary.

That which is called the Painted Lady Sweet William, is a very beautiful variety; the stalks of this do not rise so high as most of the other; the bunches of flowers are larger, and produced more in the form of an umbel, the flowers standing equal in height, make a better appearance: there are others whose stalks rise three feet high, and the flowers of a very deep red or scarlet colour. These all flower at the same time with the Carnations, which renders them less valuable, because they have no scent.

The single kinds of these flowers are generally propagated by seeds, which must be sown the latter end of March or the beginning of April, in a bed of light earth, and in June they will be fit to transplant out; at which time you must prepare some beds ready for them, and set them at six inches distance every way: in these beds they may remain till Michaelmas, at which time they may be transplanted into the borders of the pleasure-garden or wilderness.

These will flower the next year in June, and perfect their seeds in August, which you should save from the best coloured flowers for a supply.

They may be also propagated by slipping their roots at Michaelmas; but this is seldom practised, since their seedling roots will always blow the strongest, and new varieties are obtained yearly.

The four sorts with double flowers are, 1. The broad-leaved sort, which hath very double flowers, of a deep purple colour inclining to blue, which bursts its pods, so that it is not so much esteemed as the others, and therefore has been less regarded, and is now almost totally banished the gardens of the curious. 2. The Double Rose Sweet William, whose flowers are of a fine deep Rose colour, and smell sweet; this is much valued for the beauty and sweetness of its flowers; the empalement (or pods) of these flowers never burst, so the flowers remain with their petals fully expanded, and do not hang down loosely as those of the former. 3. The Mule, or Fairchild's Sweet William; it hath narrower leaves than either of the former, and is of that variety called Sweet John: this was said to have been produced from seeds of a Carnation, which had been impregnated by the farina of the Sweet William; the flowers of this are of a brighter red colour than either of the former, their bunches are not quite so large, but the flowers have an agreeable odour. The fourth sort has fine variegated flowers.

The double kinds are propagated by layers, as the Carnations; they love a middling soil, not too light, nor too heavy or stiff, nor too much dunged, which very often occasions their rotting: these continue flowering for a long time, and are extremely beautiful, especially the Mule, which produces two full blooms of flowers, one in June, and the other in July. This is very subject to canker and rot away, especially if planted in a soil over wet or too dry, or if watered with sharp spring water. These flowers being planted in pots, are very proper to adorn court-yards at the time they are in flower.

The China Pink is generally supposed an annual plant, because the plants which are raised from seeds flower and produce ripe seeds the same season, so their roots are not often preserved; but where they are planted on a dry soil, they will continue two years, and the second year will produce a greater number of flowers than the first. There are a great variety of very rich colours in these flowers, which annually vary when raised from seeds. The double flowers of this sort are most esteemed, though the colours of the single are more distinct and beautiful; for the multiplicity of petals in the double flowers, in a great measure, hides the deep shades, which are toward the lower part of the petals.

These plants are propagated by seeds, which should be sown upon a gentle hot-bed about the beginning of April; this moderate heat is only intended to forward the vegetation of the seeds, therefore when the plants come up, they must have a large share of air admitted to them, to prevent their drawing up weak; and as soon as the weather will permit, they must be exposed to the open air; in about three weeks or a month after, the plants will be fit to remove; then they should be carefully taken up with good roots, and planted in a bed of rich earth, at about three inches asunder, being careful to shade them from the sun till they have taken new root, and in dry weather they must have water three or four times a week. The farther care is to keep them clean from weeds till the end of May, at which time they may be transplanted to the places where they are designed to remain for flowering, when they may be taken up with large balls of earth to their roots, so as scarcely to feel their removal, especially if it happens to rain at that time.

As these plants do not grow large, so when they are planted singly in the borders of the flower-garden, they do not make so fine an appearance, as where they are planted by themselves in beds; or if they are planted

D I C

planted in small clumps, of six or eight roots in each, where the flowers being of different colours, set off each other to advantage.

Those who are curious in these flowers, take particular care in saving their seeds, for they never permit any single flowers to stand among their double, but pull them up as soon as they shew their flowers, and also draw out all those which are not of lively good colours; where this is observed, the flowers may be kept in great perfection; but where persons have trusty friends, who live at some distance, with whom they can exchange seeds once in two or three years, it is much better so to do, than to continue sowing seeds in the same place many years in succession, and this holds true in most sorts of seeds: but the great difficulty is to meet with an honest person of equal skill, who will be as careful in the choice of his plants for seed, as if he was to sow them himself.

DIAPENSIA. See SANICULA.

DICTAMNUS. Lin. Gen. Plant. 468. Fraxinella. Tourn. Inst. R. H. 430. tab. 243. White Dittany, or Fraxinella; in French, *Fraxinelle*. This plant was titled Fraxinella, from Fraxinus the Ash-tree, the leaves of this having some resemblance in their form, to those of the Ash-tree, so it was called Little Ash. But as this plant has been long mentioned under the title of Dictamnus albus, i. e. *White Dittany* in the dispensaries, so Dr. Linnæus has adapted that title to this genus.

The CHARACTERS are,

The empalement of the flower is composed of five small oblong leaves, ending in points. The flower hath five oblong petals which are unequal, two of them turning upward, two are oblique on the sides, and one turns downward. It hath ten rising stamina, which are as long as the petals, which are situated between the two side petals; they are not equal in length, and are terminated by obtuse four-cornered summits standing erect. In the center is situated a five-cornered germen, supporting a short incurved style, crowned by an acute stigma; the germen afterward becomes a capsule with five cells, each having a compressed margin, which spreads open at their exterior parts, but join together at their inner, opening with two valves, and inclosing several roundish, hard, shining seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flower having ten stamina and one style.

We have but one distinct SPECIES of this genus, viz.

DICTAMNUS (*Albus*). Hort. Cliff. 161. Fraxinella. Clus. Hist. 99. and the Dictamnus albus, vulgò Fraxinella. C. B. P. 222. *White Dittany*, commonly called Fraxinella. There are three varieties of this plant, one with a pale red flower striped with purple, another with a white flower, and one with shorter spikes of flowers; but as I have observed them to vary when propagated by seeds, so I esteem them only seminal varieties.

This is a very ornamental plant for gardens, and as it requires very little culture, so deserves a place in all good gardens. It hath a perennial root, which strikes deep into the ground, and the head annually increases in size; these send up many stalks, which rise from two to three feet high, garnished with winged leaves placed alternate, composed of three or four pair of oblong lobes, terminated by an odd one: they are smooth and stiff, sitting close to the midrib, which hath a longitudinal furrow on the upper side; the lobes (or small leaves) placed on each side the midrib, are oblique, but those which terminate the leaf have their sides equal. The flowers are produced in a long pyramidal loose spike or thyrse; on the top of the stalk, which is nine or ten inches long; the flowers of one sort is white, and of the other they are of a pale red, marked with red or purple stripes. The whole plant when gently rubbed, emits an odour like that of Lemon peel, but when bruised has something of a balsamic scent. It flowers the latter end of May, and in June, and the seeds ripen in September.

These plants are propagated by seeds, which, if sown

D I E

in the autumn soon after they are ripe, the plants will appear the following April; but when they are kept out of the ground till the spring, the seeds seldom succeed; or if they do grow, it is the following spring before the plants appear, so that a whole year is lost. When the plants come up, they must be constantly kept clean from weeds; and in the autumn when their leaves decay, the roots should be carefully taken up, and planted in beds at six inches distance every way; these beds may be four feet broad, and the paths between them two, that there may be room enough to pass between the beds to weed them. In these beds the plants may stand two years, during which time they must be constantly kept clean from weeds; and if they thrive well, they will be strong enough to flower; so in the autumn they should be carefully taken up, and planted in the middle of the borders of the flower-garden, where they will continue thirty or forty years, producing more stems of flowers in proportion to the size of the roots. All the culture these require, is to be kept clean from weeds, and the ground about them dug every winter. The roots of this plant are used in medicine, and esteemed cordial and cephalic, resisting putrefaction and poison, and are useful in malignant and pestilential distempers, as also in epilepsies.

DICTAMNUS CRETICUS. See ORIGANUM.

DIERVILLA. Tourn. Act. R. Par. 1706. Lonicera. Lin. Gen. Plant. 210.

The title of this genus was given it by Dr. Tournefort, after Mr. Dierville, a surgeon, who brought this plant from Acadia.

The CHARACTERS are,

The empalement of the flower is cut into five parts, almost to the bottom; the flower is of one leaf, having a tube at the bottom, but is cut into five parts at the top, and has the appearance of a lip flower; it hath five stamina, which are terminated by oblong summits, which are equal with the petal. At the bottom of the flower is situated an oval germen fixed to the empalement, supporting a slender style equal with the stamina, crowned by an obtuse stigma; the germen afterward becomes a pyramidal berry, divided into four cells, which contain small round seeds.

This genus of plants is ranged in the fourth section of Tournefort's third class, which includes the plants with a tubulous anomalous flower of one leaf. It is ranged by Dr. Linnæus under his genus of Lonicera, in the first section of his fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

We know but one SPECIES of this genus at present, viz.

DIERVILLA (*Lonicera*) *Acadiensis fruticosa, flore luteo.* Act. R. Par. 1706. *Shrubby Dierville of Acadia with a yellow flower.* This is the Lonicera racemis terminalibus foliis serratis. Lin. Sp. Plant. 275. *Lonicera with bunches of flowers terminating the branches, and sawed leaves.*

This plant grows naturally in the northern parts of America, from whence it was brought to Europe, and is now propagated in the gardens for sale. It hath woody roots which spread far in the ground, and put out shoots at a distance from the principal stalk, whereby it multiplies greatly: the stalks are ligneous, and seldom rise more than a foot and a half high; these are garnished with oblong heart-shaped leaves, ending in acute points; they are very slightly sawed on their edges, and are placed opposite, sitting close to the stalks: the upper part of the stalks are garnished with flowers, which usually come out from the side of the stalk at the sitting on of the leaves, and also at the top of the stalks; there are two or three flowers sustained upon each foot-stalk: they are of a pale yellow, and being small, make no great appearance. These come out in May, and if the season proves moist and cold, they frequently flower again in August.

It is easily propagated by suckers, which it sends out in plenty, and loves a moist soil and shady situation, where the cold will never injure it.

DIGITALIS.

D I G

DIGITALIS. Lin. Gen. Plant. 676. Tourn. Inst. R. H. 164. tab. 73. Raii Meth. Plant. 89. Foxglove; in French, *Digitale*.

The CHARACTERS are,

It hath a permanent empalement, which is cut into five parts; the flower is bell-shaped, of one petal, with a large open tube, whose base is cylindrical and contracted, but the brim is divided into four parts slightly; the upper lip spreading and indented at the top, the lower is larger. It hath four stamina, which are inserted in the base of the petal, two being longer than the other, which are terminated by bipartite acuminate summits; the flower being past, the germen swells to an oval capsule, having two cells sitting on the empalement, inclosing many small angular seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled *Didynamia Angiospermia*, the flower having two long and two shorter stamina, and the seeds being included in a capsule.

The SPECIES are,

1. **DIGITALIS** (*Purpurea*) calycinis foliolis ovatis acutis, corollis obtusis, labio superiore integro. Hort. Upsal. 178. Foxglove whose small leaves of the empalement are oval and acute, the petals obtuse, and the upper lip entire. *Digitalis purpurea folio aspero.* C. B. P. 243. Purple Foxglove with a rough leaf, or common Foxglove.
2. **DIGITALIS** (*Thapsi*) foliis decurrentibus. Lin. Sp. 867. Foxglove with running leaves. *Digitalis Hispanica purpurea minor.* Tourn. Inst. 165. Lesser Spanish purple Foxglove.
3. **DIGITALIS** (*Lutea*) calycinis foliolis lanceolatis corollis acutis labio superiore bifido. Hort. Upsal. 178. Foxglove with spear-shaped leaves to the empalement, an acute petal, whose upper lip is bifid. *Digitalis minor lutea, parvo flore.* C. B. P. 244. Lesser yellow Foxglove with a small flower.
4. **DIGITALIS** (*Magno flore*) foliolis calycinis linearibus, corollis acutis, labio superiore integro, foliis lanceolatis. Foxglove with long narrow leaves to the empalement, an acute petal, whose upper lip is entire, and spear-shaped leaves. *Digitalis lutea, magno flore.* C. B. P. 244. Yellow Foxglove with a larger flower.
5. **DIGITALIS** (*Ferruginea*) calycinis foliolis ovatis obtusis, corollæ labio inferiore longitudine floris. Lin. Sp. Plant. 622. Foxglove with oval blunt leaves to the empalement, and the lower lip of the petal as long as the flower. *Digitalis angustifolia, flore ferrugineo.* C. B. P. 244. Narrow-leaved Foxglove with an iron-coloured flower.
6. **DIGITALIS** (*Canariensis*) calycinis foliolis lanceolatis, corollis bilabiatis acutis, caule fruticoso. Lin. Sp. Plant. 622. Foxglove with spear-shaped leaves to the empalement, an acute petal with two lips, and a shrubby stalk. *Digitalis acanthoides Canariensis frutescens, flore aureo.* Hort. Amst. 2. p 105. Shrubby Canary Foxglove like Bearbreech, with a golden flower.
7. **DIGITALIS** (*Orientalis*) calycinis foliolis acutis, foliis ovato-lanceolatis nervosis. Foxglove with acute leaves to the empalement, and oval, spear-shaped, veined leaves. *Digitalis lutea non ramosa, scorzonæræ folio.* Buxb. Cent. 25. Yellow unbranched Foxglove with a leaf like *Scorzonera*.

The first sort grows naturally by the side of hedges in shady woods in most parts of England, so is rarely cultivated in gardens. This is a biennial plant, which the first year produces a great tuft of long rough leaves which are hairy; the second year it shoots up a strong herbaceous stalk, which rises from three to four feet high, garnished with leaves of the same form as the lower, but they gradually lessen upward, so those which are intermixed with the flowers on the top are very narrow. The flowers grow in a long loose thyrse, standing only on one side of the stalk; they are large, tubulous, and shaped like a thimble, of a purple colour, with several white spots on the under lip; these flowers are succeeded by oval capsules with two cells, which are filled with dark brown seeds. It flowers in June, and the seeds ripen in autumn; if they are permitted to scatter, the plants

D I G

will come up in the spring, and become troublesome weeds; but whoever has a mind to cultivate it, should sow the seeds in autumn, for those which are sown in the spring seldom succeed, or at least lie one year in the ground before they grow. This plant stands in the list of medicinal simples of the dispensaries, and there is an ointment made of the flowers, and May-butter, which has been in good esteem.

There is a variety of this with a white flower, which is found growing naturally in some parts of England, which differs from this only in the colour of the flower and leaves; but this difference is permanent, for I have cultivated it more than thirty years in the garden, and have never found it vary.

The second sort grows naturally in Spain, from whence I received the seeds; this plant seldom rises much more than a foot and a half high; the lower leaves are ten inches long, and three broad in the middle; they are soft, woolly, and roughly veined on their under side; the stalks are garnished with leaves of the same shape, but smaller; the upper part of the stalk hath a short thyrse of purple flowers like those of the common sort, but they are smaller, and the segments of the petal are acute. This plant retains its difference when cultivated in gardens.

The third sort hath very long obtuse leaves near the root; the stalk is small, and rises from two to three feet high, the lower part being pretty closely garnished with smooth leaves, about three inches long and one broad, ending in obtuse points: the upper part of the stalk, for ten inches in length, is adorned with small yellow flowers, which are closely ranged on one side of the stalk, having a few very small acute leaves placed between them, which are situated on the opposite side of the stalk; the upper lip of the flower is entire, and the petal is obtuse. It flowers in June, and the seeds ripen in autumn.

The fourth sort hath long smooth-veined leaves at the bottom; the stalk is strong, and rises two feet and a half high, garnished with leaves which are five inches long, one and a half broad, ending in acute points; these have many longitudinal veins, and are slightly sawed on their edges; the upper part of the stalk is adorned with large yellow flowers, nearly of the size of those of the common sort, the brim having acute points, and the upper lip entire. This flowers and ripens its seeds about the same time as the former.

The fifth sort hath narrow smooth leaves, which are entire; the stalk rises near six feet high, and puts out some slender branches from the side toward the bottom; the lower part of the stalks is garnished with very narrow small leaves, three inches long, and one third of an inch broad; the flowers terminate the stalk, growing in a very long spike, with very few leaves between them, and those very small; the empalement is divided into four obtuse parts, the lower lip extending much longer than the upper. The flowers are of an iron colour, and appear in June.

The sixth sort grows naturally in the Canary Islands, from whence the seeds were first brought to England; and many of the plants were raised in the bishop of London's gardens at Fulham, part of which were sent to the royal gardens at Hampton Court, and some were sent over to the gardens in Holland: those which were sent to Hampton Court, were preserved there a few years, but by the ignorance of the gardeners, to whose care those gardens were committed, this, with many other valuable plants, were soon destroyed.

This plant hath a shrubby stalk which rises to the height of five or six feet, dividing into several branches, garnished with rough spear-shaped leaves, near five inches long, and two broad in the middle, gradually decreasing to both ends, having a few short serratures on their edges; these are placed alternately on the branches; each of these branches is terminated by a loose spike of flowers, about four inches in length; the empalement of these is cut into five acute seg-

ments almost to the bottom; the upper lip is long and entire, this is arched, and immediately under it the stamina and style are situated; the lower lip is obtuse, and indented at the top; there are two acute segments on the side, which compose the chaps of the flower; there are two of the stamina longer than the other; these are crowned with roundish summits. In the bottom of the flower is situated the germen, supporting a slender style, crowned by an oval stigma; the germen afterward becomes an oval capsule, filled with small angular seeds.

This plant begins to flower in May, and there is generally a succession of flowers on the same plant, till the winter puts a stop to them, which renders the plant more valuable. It is propagated by seeds, which should be sown in pots filled with light earth, in the autumn, soon after the seeds are ripe; these pots should be plunged into an old bed of tanners bark, whose heat is gone, and in mild weather the glasses should be drawn off to admit the air; but in hard rains and frost they must be kept on, to protect the seeds from both, which frequently destroys them here when they are exposed; in the spring the plants will come up, when they should enjoy the free air in mild weather, but must be protected from the cold. When these are large enough to transplant, they should be each planted into a separate small pot filled with light earth, and placed under the frame till they have taken new root, then they should be gradually inured to the open air. During the summer season the plants should remain abroad in a sheltered situation, but in the winter they must be placed in a greenhouse, for they will not live abroad in England; they must not be kept too warm and close in the house, for they only want protection from the frost; therefore in mild weather, they should have free air constantly admitted to them, and they require frequent waterings, but they should not have it in too great plenty in winter.

The seventh sort grows naturally in Tartary, from whence the seeds were sent to the imperial garden at Petersburg, and from thence I received them. This plant hath many oval spear-shaped leaves, which are smooth, arising from the root; between these arise the stalk, which grows about a foot high, and is garnished below with smooth spear-shaped leaves, from four to five inches long, and one and a half broad in the middle, lessening gradually at both ends; these have no foot-stalks, but their base embraces the stalks half round; the upper part of the stalk is adorned by a short loose spike of yellow flowers, which are almost as large as those of the great yellow sort before-mentioned, but they are shorter. This flowers in May, and the seeds ripen in autumn.

All these sorts should be sown in the autumn; for if the seeds are sown in the spring, they commonly fail, or at least lie a whole year in the ground before they vegetate. The plants are biennial (except the seventh sort) and generally perish soon after the seeds are ripe.

DIOSCOREA. Plum. Nov. Gen. 9. tab. 26. Lin. Gen. Plant. 995.

The CHARACTERS are,

It hath male and female flowers in different plants; the male flowers have a bell-shaped perianthium of one leaf, cut into six parts, but have no petals or empalement; they have six short hairy stamina, terminated by single summits. The female flowers have the same perianthium as the male; they have no petals, but have a small three-cornered germen, supporting three styles, which are crowned by single stigmas; the perianthium afterward becomes a triangular capsule with three cells, opening with three valves, containing two compressed bordered seeds in each.

This genus of plants is ranged in the sixth section of Linnaeus's twenty-second class, intitled *Dioecia Hexandria*. The plants of this class and section have male and female flowers on different plants, and the male flowers have six stamina.

The SPECIES are,

1. **DIOSCOREA** (*Sativa*) foliis cordatis alternis, caule

- laevi tereti. Hort. Cliff. 459. *Dioscorea with heart-shaped leaves placed alternate, and a smooth taper stalk.* Dioscorea scandens, foliis tamni fructu racemoso. Plum. Nov. Gen. 9. *Climbing Dioscorea with black Briony leaves, and fruit growing in long bunches.*
2. **DIOSCOREA** (*Hastata*) foliis hastato-cordatis, caule laevi, racemis longissimis. *Dioscorea with spear-pointed heart-shaped leaves, a smooth stalk, and very long bunches of flowers.* Dioscorea scandens, folio hastato fructu racemoso. Hoult. MSS. *Climbing Dioscorea with a spear-pointed leaf, and fruit growing in bunches.*
3. **DIOSCOREA** (*Villosa*) foliis cordatis alternis, oppositifolius caule laevi. Lin. Sp. 1463. *Dioscorea with heart-shaped leaves placed alternate and opposite, and a smooth stalk.* Dioscorea scandens, folio subrotundo acuminate fructu racemoso. Hoult. MSS. *Climbing Dioscorea with a roundish pointed leaf, and fruit growing in long bunches.*
4. **DIOSCOREA** (*Bulbifera*) foliis cordatis, caule laevi bulbifera. Flor. Zeyl. 360. *Dioscorea with heart-shaped leaves, and a smooth stalk bearing bulbs.* Volubilis nigra, radice albâ aut purpureâ maxima tuberosa esculenta, caule membranulis extantibus alato, folio cordato nervoso. Sloan. Cat. Jam. 46. *The Yam, or Yammes.*
5. **DIOSCOREA** (*Oppositifolia*) foliis oppositis ovatis acuminatis. Lin. Sp. 1483. *Dioscorea with oval-pointed leaves growing opposite.*
6. **DIOSCOREA** (*Digitata*) foliis digitatis. Hort. Cliff. 459. *Dioscorea with hand-shaped leaves.* Nureni Kelengu. Hort. Mal. 7. p. 67.

The first sort grows naturally in most of the islands in the West Indies. I received the seeds of this sort from Jamaica, where the late Dr. Houstoun found it growing plentifully. This hath slender climbing stalks, which fix themselves to any support near them, and rise to the height of eighteen or twenty feet, garnished with heart-shaped leaves, ending with acute points, having five longitudinal veins, which arise from the foot-stalks, which diverge toward the sides, but meet again at the point of the leaves. They stand upon pretty long foot-stalks, from the base of which arise the branching spikes of flowers, which are small, and have no beauty; the female flowers are succeeded by three-cornered oblong capsules, having three cells, each containing two compressed seeds.

The second sort differs from the first in the shape of their leaves, these having two round ears at their base, but the middle extends to an acute point, like that of an halbert. The bunches of flowers are longer, and are looser placed than those of the former sort.

The third sort hath broad, round, heart-shaped leaves, which end in acute points; these have many longitudinal veins which arise from the foot-stalk, and diverge to the side, but afterward join at the point of the leaf; the flowers come out on long loose strings, standing on short foot-stalks; the female flowers are succeeded by three-cornered oblong capsules, with three cells, having compressed bordered seeds.

The fourth sort hath triangular winged stalks, which trail upon the ground and extend to a great length; these frequently put out roots from the joints as they lie upon the ground, whereby the plants are multiplied. The roots of this plant are eaten in many parts of both Indies, where the plants are much cultivated.

The fifth sort grows naturally in Virginia, and in other parts of North America. This hath a smooth stalk which climbs on the neighbouring plants, and rises five or six feet high, garnished with heart-shaped leaves, which are placed opposite; they are covered with small hairs, and have several longitudinal veins. The flowers come out from the side of the stalk in the same manner as the other sorts, but have no beauty. These plants are preserved in some curious botanic gardens for the sake of variety; but as they have no beauty, there are few persons who will allow them a place, especially as most of the sorts require a good stove to preserve them through the winter in England.

These

These plants may be propagated by laying their branches into the ground, which in about three months will put out roots, and may then be taken from the old plants, and planted into separate pots, which should be plunged into the tan-bed in the stove; during the winter these plants should have but little water given them; but in summer, when they are growing vigorously, they should be watered three or four times a week, and in warm weather the glasses should be opened to admit a large share of free air. These plants rarely flower in England, but when the seeds are sent from America, they should be immediately sown in pots, and plunged into a hot-bed, where, if the seeds are sown early in the spring, the plants will come up the same season; but when they are sown late, the seeds often remain in the ground till the following spring before they vegetate; therefore when the plants do not come up the first season, the pots should be screened from the frost the following winter, and put into a new hot-bed in the spring, which will bring up the plants, if the seeds were good. The fourth sort is much cultivated by the inhabitants of the islands in America, and is of great use to them for feeding of their negroes; and the white people make puddings of their roots, when ground to a sort of flour. This plant is supposed to have been brought from the East to the West Indies, for it has not been discovered to grow wild in any part of America; but in the island of Ceylon, and on the coast of Malabar, it grows in the woods, and there are in those places a great variety of sorts.

This sort, which is chiefly cultivated in the West Indies, has a root as big as a man's leg, of an irregular form, and of a dirty brown colour on the outside, but when cut, are white and mealy within. The stalks of this plant are triangular and winged; the leaves are heart-shaped, having two ears, somewhat like those of Arum. These stalks climb to the height of ten or twelve feet, when they grow near trees or shrubs, to which they fasten themselves, otherwise they trail upon the ground.

This plant is propagated by cutting of the root into pieces, observing to preserve an eye or bud to each, as is practised in planting of Potatoes; each of these being planted will grow, and produce three or four large roots. In America they are commonly six or eight months in the ground before the roots are taken up for use. The roots are roasted or boiled, and eaten by the inhabitants, and sometimes are made into bread.

In some curious gardens this plant is preserved for the sake of variety, but it is so tender as not to live in England, unless it is placed in a warm stove. As these roots are frequently brought from America, whoever hath an inclination to preserve the plant, may cut them in the manner before described, and plant each piece in a pot filled with fresh earth, and plunged into a hot-bed of tanners bark, and give them little water until they shoot, lest they should rot. With this management I have had the shoots ten feet high, but the roots have not grown to any great size with me. This plant will not thrive in the open air in the warmest time of the year, so must constantly be kept in the bark-stove.

DIOSMA. Lin. Gen. Plant. 241. Spiræa. Com. Rar. Plant. 2. African Spiræa, vulgò.

The CHARACTERS are,

The flower hath a permanent empalement, which is divided into four acute segments, which are plain at their base; it hath five obtuse petals, which spread open and are as long as the empalement; it hath five stamina terminated by oval erect summits, and a five-pointed hollow nectarium sitting on the germen, from which arises a single style, crowned by an obsolete stigma. The germen afterward becomes a fruit composed of five compressed capsules, which open lengthways, each inclosing one smooth oblong seed.

This genus of plants is ranged in the first section of Linnaeus's fifth class, intitled Pentandria Monogynia, the flowers having five stamina and one style.

The SPECIES are,

1. **DIOSMA** (*Oppositifolius*) foliis subulatis acutis oppositis. Hort. Cliff. 71. *Diosma with acute oval-shaped leaves placed opposite.* Spiræa Africana, foliis cruciatim positis. Com. Rar. Plant. 1. tab. 1. *African Spiræa with leaves placed in form of a cross.*
2. **DIOSMA** (*Hirsuta*) foliis linearibus hirsutis. Hort. Cliff. 71. *Diosma with narrow hairy leaves.* Spiræa Africana odorata, foliis pilosis. Com. Rar. Plant. 3. tab. 3. *Sweet African Spiræa with hairy leaves.*
3. **DIOSMA** (*Rubra*) foliis linearibus acutis glabris, carinatis subtus bifarium punctatis. Lin. Sp. Plant. 198. *Diosma with smooth, narrow, acute leaves, which are spotted on their under side.* Spiræa Africana odorata, floribus suaverubentibus. Com. Rar. Plant. 2. *Sweet African Spiræa with soft red flowers.*
4. **DIOSMA** (*Erricoides*) foliis lineari-lanceolatis subtus convexis, bifariam imbricatis. Lin. Sp. Plant. 198. *Diosma with narrow spear-shaped leaves, which are convex on their under side, and imbricated two ways.* Spiræa Africana ericæ bacciferae foliis. Raii Hist. 91. *African Spiræa with leaves like the Berry-bearing Heath.*
5. **DIOSMA** (*Lanceolata*) foliis lanceolatis glabris. Lin. Sp. 287. *Diosma with smooth spear-shaped leaves.* Spiræa Africana, Saturejæ foliis brevioribus. Raii Dendr. 91.

The first sort rises to the height of three feet; the branches are very long and slender, and are produced from the stem very irregularly; the leaves are placed crossways, and are pointed; these are every evening closed up to the branches. The flowers are produced along the branches from between the leaves; and in the evening, when these flowers are expanded, and the leaves are closely embracing the stalks, the whole plant appears as if covered with spikes of white flowers; and as these plants continue a long time in flower, they make a fine appearance when the plants are intermixed with other exotics in the open air.

The second sort has been long known under the title of Spiræa Africana odorata, foliis pilosis, or *Sweet-scented African Spiræa, with hairy leaves.* This sort makes a very handsome shrub, growing to the height of five or six feet; the stalks are woody, sending out many slender branches; the leaves come out alternately on every side, which are narrow-pointed and hairy. The flowers are produced in small clusters at the end of the shoots, which are white; these are succeeded by starry seed-vessels, having five corners, like those of the starry Anise; each of these corners is a cell, having one smooth, shining, oblong, black seed; these seed-vessels abound with a resin, which affords a grateful scent, as doth also the whole plant.

The third sort is of humbler growth than either of the former, seldom rising above three feet high, and spreads out into many branches; the leaves of this sort are smooth, and resemble those of the Heath, and this plant from thence had the name of Erica Æthiopica, &c. given it by Dr. Plukenet: the flowers of this kind are produced in clusters at the end of the branches, like those of the second sort, but are smaller, and the bunches are not so large.

All these plants are propagated by cuttings, which may be planted during any of the summer months, in pots filled with light fresh earth, and plunged into a very moderate hot-bed, where they should be shaded in the day time from the sun, and frequently refreshed with water. In about two months the cuttings will have taken root, when they should be each transplanted into a small pot, and placed in a shady situation until the plants have taken fresh root, when they may be placed among other exotic plants, in a sheltered situation: these plants may remain abroad until the beginning of October or later, if the season continues favourable; for they only require to be sheltered from frost, so that in a dry airy green-house they may be preserved very well in winter, and in summer they may be exposed to the open air with other green-house plants.

These plants grow naturally at the Cape of Good Hope, from whence the seeds were sent to Europe, where

D I O

where some of the species have been long preserved in the gardens of the curious. There have been some other species in the English gardens than are here enumerated, but these are all that are at present to be found here.

The second sort frequently ripens its seeds in England; but if the seeds are not sown soon after they are ripe, they rarely grow, or they commonly lie a whole year in the ground.

DIOSPYROS. Lin. Gen. Plant. 1027. Guaiacana. Tourn. Inst. R. H. 600. tab. 371. The Indian Date Plumb.

The CHARACTERS are,

It hath hermaphrodite and female flowers on the same plant, and male flowers on separate plants; the hermaphrodite flowers have a large obtuse permanent empalement of one leaf, which is divided into four parts; the flower hath one petal which is shaped like a pitcher, and cut at the brim into four segments, which spread open; it hath eight short bristly stamina firmly joined to the empalement, terminated by oblong summits which have no farina. In the center is situated a roundish germen, supporting a single quadrifid style, crowned by an obtuse bifid stigma; the germen afterward becomes a large globular berry with many cells, each including one oblong, compressed, hard seed. The male flowers have a one-leaved empalement, cut into small acute segments; the petal is thick and four-cornered, cut into four obtuse segments which turn backward; they have eight short stamina, terminated by long, acute, twin summits, but have no germen.

This genus of plants is ranged in the second section of Linnæus's twenty-third class, intitled Polygamia Dioecia. The plants of this class and section have hermaphrodite and female flowers growing on the same plant, and the male on separate plants.

The SPECIES are,

1. **DIOSPYROS** (*Lotus*) foliorum paginis discoloribus. Lin. Sp. Plant. 1057. *Diospyros with the surface of the leaves of two colours.* Guaiacana. J. B. 2. 138. *The Indian Date Plumb.*

2. **DIOSPYROS** (*Virginiana*) foliorum paginis concoloribus. Lin. Sp. Plant. 1057. *Diospyros with the surface of the leaves of one colour.* Guaiacana Virginiana Pifhamin dicta. Boerh. Ind. alt. 2. *The Pifhamin or Persimon, and by some Pitchumon Plumb.*

The first sort is supposed to be a native of Africa, and was transplanted from thence into several parts of Italy, and also the south of France. The fruit of this tree is by some supposed to be the Lotus, which Ulysses and his companions were enchanted with. This is a tree of a middling growth in the warm parts of Europe, where there are several of them which are upward of thirty feet high; but particularly in the botanic garden at Padua there is one very old tree, which has been described by some of the former botanists, under the title of Guaiacum Patavinum. This tree produces plenty of fruit every year, from the seeds of which many plants have been raised. In England there are none of these trees, but what have been raised within a few years past, in the physic garden at Chelsea; for the seeds of which I was greatly obliged to my much honoured friend, his excellency the Chevalier Rathgeb, his imperial majesty's minister at Venice, who has also supplied me with many other curious plants, trees, and fruits, from different parts of the world, where his extensive correspondence has been employed to collect whatever rare plants he could procure; and his generosity in communicating what seeds and plants he can procure to the physic garden at Chelsea, requires this public acknowledgment.

The second sort is a native of America, but particularly in Virginia and Carolina there is great plenty of these trees growing in the woods. The seeds of this sort are frequently brought to England, where the trees are now become pretty common in the nurseries about London. This rises to the height of fourteen or sixteen feet, but generally divides into many irregular trunks near the ground, so that it is very rare to see a handsome tree of this sort. This produces

D I P

plenty of fruit in England, but they never come to perfection here. In America the inhabitants preserve the fruit until it be rotten (as is practised by Medlars in England) when they are esteemed a pleasant fruit.

These are both propagated by seeds, which will come up very well in the open ground; but if they are sown upon a moderate hot-bed, the plants will come up much sooner, and make a greater progress; but in this case the seeds should be sown in pots or boxes of earth, and plunged into the hot-bed, because the plants will not bear transplanting till autumn, when the leaves fall off; so that when the plants are up, and have made some progress, they may be inured by degrees to the open air; and in June they may be wholly exposed, and may remain abroad until November, when it will be proper to set the pots under a hot-bed frame to protect them from hard frost, which, while they are very young, may kill the tops of the plants; but they must have as much free air as possible in mild weather. The following spring, before the plants begin to shoot, they should be transplanted into a nursery, in a warm situation, where they may be trained up for two years, and then removed to the places where they are designed to remain. These are both hardy enough to resist the greatest cold of this country, after the plants have acquired strength.

DIPSACUS. Lin. Gen. Plant. 107. Tourn. Inst. R. H. 466. tab. 265. [*διψαδος*, Gr. i. e. thirsty. It is said to have taken its name by way of contrary, because it receives the dew or rain in the hollow sinus of its leaves that cohere together, by which it drives away the injuries of thirst. It is also called Labrum Veneris, from the position of its leaves, which form a sort of basin, containing a liquor that beautifies the face.] The Teazel; in French, *Chardon à Bonnetier*.

The CHARACTERS are,

It hath many florets collected in one common perianthium, which is permanent; the florets have but one petal, which is tubular, cut into four parts at the top, which are erect. They have four hairy stamina which are as long as the petal, terminated by prostrate summits; the germen is situated below the flower, supporting a slender style, crowned by a single stigma. The germen afterward becomes a column-shaped seed, inclosed in the common conical fruit, which is divided by long prickly partitions.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

The SPECIES are,

1. **DIPSACUS** (*Sylvestris*) foliis sessilibus serratis, aristis fructibus erectis. *Teazel with sawed leaves set close to the stalks, and erect beards to the fruit.* Dipsacus sylvestris. Dod. Pemp. 735. *Wild Teazel.*

2. **DIPSACUS** (*Fullonum*) foliis connatis, aristis fructibus recurvis. *Teazel with leaves joined at their base, and the beards of the fruit recurved.* Dipsacus sativus. Dod. Pemp. 735. *Cultivated Teazel.*

3. **DIPSACUS** (*Laciniatus*) foliis connatis sinuatis. Lin. Sp. Plant. 97. *Teazel with sinuated leaves joined at their base.* Dipsacus folio laciniato. C. B. P. 385. *Teazel with a lacinated leaf.*

4. **DIPSACUS** (*Pilosus*) foliis petiolatis appendiculatis. Hort. Upsal. 25. *Teazel with foot-stalks having appendices.* Dipsacus sylvestris, capitulo minore, seu. Virga. Pastoris minor. C. B. P. 385. *Wild Teazel with a smaller head, or smaller Shepherd's Rod.*

The first of these plants is very common upon dry banks in most parts of England, and is seldom cultivated in gardens, unless for the sake of variety.

The fourth sort grows naturally in many places near London, and is rarely admitted into gardens.

The third sort grows naturally in Alsace, and is kept in botanic gardens for the sake of variety; this differs from the wild Teazel in having the leaves deeply cut and jagged.

But it is the second sort only which is cultivated for use, which is called Carduus Fullorum, or Fullonum, being of so singular use in raising the knap upon woollen cloth, for which purpose there are great quantities

quantities of this plant cultivated in the west country. This plant is propagated by sowing the seeds in March, upon a soil that has been well ploughed: about one peck of this seed will sow an acre; for the plants should have room to grow, otherwise the heads will not be so large, nor in so great quantity. When the plants are come up, you must hoe them in the same manner as is practised for Turneps, cutting down all the weeds, and singling out the plants to about six or eight inches distance; and as the plants advance, and the weeds begin to grow again, you must hoe them a second time, cutting out the plants to a wider distance, for they should be, at last, left at least a foot asunder: and you should be particularly careful to clear them from weeds, especially the first summer; for when the plants have spread so as to cover the surface of the ground, the weeds will not so readily grow between them. The second year after sowing, the plants will shoot up stalks with heads, which will be fit to cut about the beginning of August; at which time they should be cut, and tied up in bunches, setting them in the sun if the weather be fair; but if not, they must be set in rooms to dry. The common produce is about an hundred and sixty bundles or staves upon an acre, which they sell for about one shilling a staff. Some people sow Caraway and other seeds among their Teazels, but this is not a good method, for the one spoils the other; nor can you so easily clear them from weeds, as when alone. Dr. Linnæus supposes this to be only a seminal variety of the common wild Teazel; but I have cultivated both the sorts more than forty years, and have never found either of them alter, so that there can be no doubt of their being distinct species.

DIRCA, Leather Wood.

The CHARACTERS are,

There is no empalement to the flower, which is club-shaped, of one petal, having a short-bellied tube, and an unequal border; it hath eight slender stamina situated in the middle of the tube, terminated by erect roundish summits, with an oval germen, supporting a slender style which is longer than the stamina, crowned by a simple stigma. The germen afterward becomes a berry with one cell, inclosing one seed.

This genus of plants is ranged in the first section of Linnæus's eighth class, intitled Octandria Monogynia, the flower having eight stamina and one style.

We know but one SPECIES of this genus, viz.

DIRCA (Palustris). Amœn. Acad. 3. p. 12. *Marsh Leatherwood.* Thymelæa floribus albis primo vere erumpentibus, foliis oblongis acuminatis, viminibus & cortice valde tenacibus. Flor. Virg. 155.

This shrub grows naturally in swamps in Virginia, Canada, and other parts of North America, where it seldom rises more than five or six feet high, but in Europe it rarely is more than half so high; it sends out many articulated branches near the root, garnished with oval leaves, of a pale yellowish colour, and smooth; the flowers come out from the side of the branches, two or three upon each foot-stalk; they are of a greenish white colour, and appear early in the spring, just at the time when the leaves begin to shoot; the flowers are seldom succeeded by seeds in England. This shrub is very difficult to propagate in Europe; for as it does not produce seeds here, it can only be increased by layers or cuttings, and these are generally two years before they put out roots; for as the shrubs grow naturally in very moist places, they are with difficulty preserved in gardens, unless they are planted in wet ground, but they are seldom injured by cold.

DITTANY, the white. See **DICTAMNUS**.

DITTANY of Crete. See **ORIGANUM**.

DOCK. See **LAPATHUM**.

DODARTIA. Lin. Gen. Plant. 698. Tourn. Cor. 47. tab. 478. [This plant was so named by Dr. Tournefort, from Monsieur Dodart, a member of the Academy of Sciences at Paris.] We have no English name for this plant.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf,

which is bell-shaped, cut into five parts at top; the flower hath one petal, is ringent, having a cylindrical diflexed tube much longer than the empalement; the upper lip rises and is indented, the lower lip spreads open and is trifid, the middle segment being narrow. It hath four stamina which incline to the upper lip, two of which are shorter than the other, and are terminated by small roundish summits. In the center is situated a round germen, supporting an awl-shaped style, crowned by a bifid obtuse stigma. The germen afterward becomes a globular capsule with two cells, filled with small seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two short stamina, and the seeds being included in a capsule.

The SPECIES are,

1. **DODARTIA (Orientalis)** foliis linearibus integerrimis glabris. Lin. Sp. Plant. 633. *Dodartia with very narrow, smooth, entire leaves. Dodartia Orientalis, flore purpurascens. Tourn. Cor. 47. Eastern Dodartia with a purplish flower.*

2. **DODARTIA (Linaria)** foliis radicalibus oblongo-ovatis, serratis, caulinis linearibus integerrimis floribus spicatis terminalibus. *Dodartia with oblong, oval, sawed leaves at the bottom, those on the stalks narrow and entire, and flowers growing in spikes at the end of the stalks. Linaria bellidis folio. C. B. P. 212. Toad Flax with a Daisy leaf.*

The first sort was discovered by Dr. Tournefort near mount Ararat in Armenia, from whence he sent the seeds to the royal garden at Paris, where they succeeded, and from thence most of the curious gardens in Europe have been supplied with this plant. This plant having characters which are different from all those of Tournefort's Institutions, he constituted this genus, and gave it the title from Monsieur Dodart, member of the Royal Academy of Sciences at Paris, and physician to her Royal Highness the Princess of Conti.

It hath a perennial root which creeps far under the surface, and sends out new stalks at a great distance from the parent plant; these stalks are firm, a little compressed, and grow a foot and a half high, sending out several side branches, garnished with long, fleshy, narrow leaves placed opposite, of a deep green colour; those on the lower part of the stalk are shorter and broader than those above, but those on the upper part of the stalk are entire; and at these joints the flowers come out singly on each side the stalk, sitting close to it; these are near an inch long; the bottom is tubulous, but divides into two lips above; the upper lip is hollow like a spoon, the convex side standing upward, and is divided into two parts; the lower lip is divided into three parts, the middle being the narrowest. The flower is of a deep purple colour, and appears in July, and is rarely succeeded by seeds in England. It propagates very fast by its creeping roots, so that when it is once established in a garden, it will multiply fast enough; it loves a light dry soil, and may be transplanted either in autumn when the stalks decay, or in the spring before the new stalks arise.

The second sort is a biennial, or at most a triennial plant, which frequently perishes soon after the seeds are ripe. This sends out from the root several oblong leaves, which are near four inches long, narrow at their base, but increase in width upward, where they are about an inch broad, rounded at the end, and deeply sawed on the edges; between these arise the stalks, which grow a foot high, their lower parts being garnished with leaves of the same form as the lower leaves, but much smaller; the upper leaves are very narrow and entire. The flowers grow in spikes on the top of the stalks; they are very small and white, but are shaped like those of the former sort. This is propagated by seeds, which should be sown in autumn soon after they are ripe, upon a border of light earth, where they are designed to remain. When the plants appear the following spring, they must be thinned, and kept clear from weeds, which is all the

culture they require : the second year they will flower and seed, after which the plants usually decay ; when the seeds are sown in the spring, the plants never come up the same year.

DODECATHEON. See MEADIA.

DOG'S TOOTH. See ERYTHRONIUM.

DOG-WOOD. See CORNUS.

DOLICHOS, Kidney Bean.

The CHARACTERS are,

The empalement is of one leaf, short, and cut into four equal segments. The flower is of the butterfly kind, having a large round vexillum which is reflexed. The wings are oval, obtuse, and the length of the keel. The keel is moon-shaped, compressed, and the top ascends ; it hath nine stamina joined below, and a single one standing separate, terminated by single summits, with a linear compressed germen, supporting an ascending style, crowned by a bearded stigma. The germen afterward becomes a large oblong pod with two valves, containing compressed elliptical seeds.

This genus is distinguished from *Phaseolus*, by the keel of the flower not being spiral.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled *Diadelphia Decandria*, the flower having ten stamina in two bodies.

The SPECIES are,

1. **DOLICHOS** (*Lablab*) volubilis, leguminibus ovato-acinaciformibus, seminibus ovatis hilo arcuato versus alteram extremitatem. Prod. Leyd. 368. *Dolichos* with a winding stalk, oval bill-shaped pods, and oval seeds. *Phaseolus Ægyptiacus nigro semine*. C. B. P. 341.

2. **DOLICHOS** (*Uncinatus*) volubilis, pedunculis multifloris leguminibus cylindricis hirsutis apice unguiculo subulato hamato, caule hirtio. Lin. Sp. 1019. *Dolichos* with a winding stalk, many flowers on each foot-stalk, cylindrical hairy pods, whose points are crooked and awl-shaped.

3. **DOLICHOS** (*Pruriens*) volubilis, leguminibus racemosis hirtis, valvulis subcarinatis, pedunculis ternis. Jacq. Amer. 27. *Dolichos* with a winding stalk, hairy pods growing in a racemus, almost boat-shaped valves, and each foot-stalk having three pods.

4. **DOLICHOS** (*Urens*) volubilis, leguminibus racemosis hirtis transversim lamellatis, seminibus hilo cinctis. Jacq. Amer. 27. *Dolichos* with a winding stalk, hairy pods in a racemus, whose hairs are situated in transverse lamellæ, commonly called *Cow-itch*.

There are many other species of this genus, as there are also of *Phaseolus* ; but as there are few of them cultivated in the English gardens, it would swell this work to a great bulk, if they were all inserted which have come to our knowledge, as the author has cultivated more than sixty species, beside many varieties.

The two first sorts here mentioned, are cultivated in warm countries for the table, but in England these seldom perfect their seeds ; and were they to thrive here as well as in the warm countries, they would be little esteemed, because we have much better sorts in our gardens already ; for the scarlet flowering Kidney Bean is preferable to all the other sorts for eating, so deserves our care to cultivate it more than any other.

The third and fourth sorts are sometimes preserved in botanic gardens, but especially the fourth, whose pods are closely covered with stinging hairs, commonly known by the title of *Cow-itch* ; but these are too tender to thrive in the open air in this country, so that whoever is desirous to have the plants, should sow their seeds in a hot-bed in March ; and when the plants are come up, they should be each planted in a separate pot, and plunged into the hot-bed again, being careful to shade them till they have taken root ; after which they must have fresh air every day admitted to them, in proportion to the warmth of the season ; and when the plants are too tall to remain in the hot-bed, they should be removed into the bark-stove, where, if they are allowed room to run, they will flower and perfect their seeds.

DORIA. See SOLIDAGO and OTHONNA.

DORONICUM. Lin. Gen. Plant. 862. Tournef. Inst. R. H. 487. tab. 477. *Leopard's Bane*.

The CHARACTERS are,

It hath a flower composed of several hermaphrodite florets, which are situated in the center, and form the disk, and of female florets which compose the rays ; these are included in one common empalement, which hath a double series of leaves as long as the rays. The hermaphrodite florets are funnel-shaped, and cut into five parts at the top ; these have five short hairy stamina, terminated by cylindrical summits. In the bottom is situated the germen, supporting a slender style, crowned by an indented stigma ; the germen afterward becomes a single, oval, compressed seed, crowned with hairy down. The female florets are formed like a tongue, which are spread out and compose the border ; these have a germen, supporting a style, crowned by two reflexed stigmas, but have no stamina ; the germen becomes a single furrowed seed, covered with a hairy down.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, intitled *Syngenesia Polygamia superflua*. The plants of this section have female and hermaphrodite flowers, which are both fruitful.

The SPECIES are,

1. **DORONICUM** (*Pardalianches*) foliis cordatis obrutis, denticulatis radicalibus periolatis, caulinis amplexicaulibus. Lin. Mat. Med. 394. *Leopard's Bane* with obtuse, heart-shaped, indented leaves, those from the root having foot-stalks, and these above embracing the stalks. *Doronicum maximum*, foliis caulem amplexantibus. C. B. P. 184. *Greatest Leopard's Bane* with leaves embracing the stalks.

2. **DORONICUM** (*Plantagineum*) foliis ovatis acutis, subdentatis, ramis alternis. Hort. Cliff. 411. *Leopard's Bane* with oval-pointed leaves indented at bottom, and alternate branches. *Doronicum plantaginis folio*. C. B. P. 184. *Leopard's Bane* with a Plantain leaf.

3. **DORONICUM** (*Helveticum*) foliis lanceolatis, denticulatis, subtus tomentosis, caule unifloro. Prod. Leyd. 160. *Leopard's Bane* with spear-shaped indented leaves, woolly on their under side, and one flower on a stalk. *Doronicum Helveticum incanum*. C. B. P. 185. *Hairy Helvetian Leopard's Bane*.

4. **DORONICUM** (*Bellidiastrum*) caule nudo simplicissimo unifloro. Hort. Cliff. 500. *Leopard's Bane* with a naked single stalk having one flower. *Bellis sylvestris media caule carens*. C. B. P. 261. *Middle wild Daisy* having a tall stalk.

The first sort grows naturally in Hungary, and upon the Helvetian mountains, but is frequently preserved in the English gardens. It hath thick fleshy roots, which are divided into many knots or knees, sending out strong fleshy fibres, which penetrate deep into the ground ; and from these arise in the spring a cluster of heart-shaped leaves, which are hairy, and stand upon foot-stalks ; between these arise the flower-stalks, which are channelled and hairy, growing near three feet high, putting out one or two smaller stalks from the side, which grow erect, and are garnished with one or two heart-shaped leaves, closely embracing the stalks with their base ; each stalk is terminated by one large yellow flower, composed of about twenty-four rays or female florets, which are about an inch long, plain, and indented in three parts at the top. In the center is situated a great number of hermaphrodite florets, which compose the disk ; these are tubulous, and slightly cut at the top into five parts. The flowers appear in May, and are succeeded by seeds which ripen in July ; these are crowned by a hairy down, which serves to convey them to a distance.

This plant multiplies very fast by its spreading roots, and if the seeds are permitted to scatter, they will produce plants wherever they happen to fall, so that it becomes a weed where it is once established ; it loves a moist soil and a shady situation.

The second sort hath oval leaves, ending in acute points ; these are indented on their edges toward their base, but their upper parts are entire ; the stalks rise about two feet high ; each is terminated by a large yellow

yellow flower, like those of the former sort; the stalks of this sort have two or three leaves, which are placed alternately, and their base fits close to the stalks; these are not so hairy as those of the former sort; it flowers about the same time with that, and the seeds ripen well in England. This grows naturally in Portugal, Spain, and Italy, but is equally hardy with the first, and multiplies in as great plenty; the root is perennial.

The third sort hath longer leaves than either of the former, which are covered with a hoary down on their under side, and are indented on their edges; the stalks are single, and have seldom more than one leaf upon each; these grow a foot and a half high, and are terminated by a single flower on the top, like those of the former sorts. This grows naturally on the Pyrenees and Helvetian mountains. It delights in a moist soil and a shady situation, and propagates in plenty, either from seeds or by parting the roots: it flowers and seeds about the same time with the former.

The fourth sort grows naturally on the Alps and Pyrenean mountains; this hath a perennial root; the leaves are like of the lesser Daisy, but longer, and not so broad. The flower grows upon a naked foot-stalk, which is near a foot long; the roots seldom send out more than one stalk; the rays of the flower are white, and very like those of the common Daisy; the disk of the flower is yellow, which is composed of hermaphrodite flowers.

This plant is preserved in botanic gardens for the sake of variety, but the flowers make little better appearance than those of the common Field Daisy, only they stand upon much taller foot-stalks. It must have a shady situation and a moist soil, otherwise it will not thrive in this country; it is propagated by parting of the roots, for the seeds do not ripen well in England. I received this from Verona, near which place it grows naturally.

The roots of the first sort have been sometimes used in medicine, some having commended it as an expeller of the poison of scorpions; but others reckon it to be a poison, and affirm that it will destroy wolves and dogs.

The other sorts which have been formerly ranged under this genus, are now separated, and may be found under the title ARNICA.

DORSIFEROUS plants [of dorsum, the back, and fero, Lat. to bear,] such plants as are of the capillary kind, without stalk, and that bear their seeds on the backside of their leaves.

DORSTENIA. Plum. Nov. Gen. 29. tab. 8. Lin. Gen. Plant. 147. [This plant was so named by father Plumier, from Dr. Dorsten, a German physician, who published a history of plants in folio.] Contrayerva.

The CHARACTERS are,

It hath one common plain involucre situated vertically, upon which sit many small florets as in a disk; these have no petals, but have four short slender stamina, terminated by roundish summits. In the center is situated a roundish germen, supporting a single style crowned by an obtuse stigma; the germen afterward becomes a single seed, inclosed in the common fleshy receptacle.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

The SPECIES are,

1. **DORSTENIA** (*Contrayerva*) acaulis, foliis pinnatifido-palmatis, serratis, floribus quadrangulis. Lin. Sp. 176. Dwarf Dorstenia with many pointed, hand-shaped, sawed leaves, and flowers placed on a quadrangular receptacle. Dorstenia sphondylii folio, dentariæ radice. Plum. Nov. Gen. 29. Dorstenia with a Cow Parsnep leaf, and a Toothwort root.
2. **DORSTENIA** (*Houstoni*) acaulis, foliis cordatis angulatis acuminatis, floribus quadrangulis. Lin. Sp. 176. Dwarf Dorstenia with angular, heart-shaped, pointed leaves, and quadrangular receptacles to the flowers. Dorstenia dentariæ radice, folio minus laciniato, placenta

quadrangulâri & undulatâ. Houst. MSS. *Contrayerva with a Toothwort root, a leaf less cut, and a quadrangular waved placenta.*

3. **DORSTENIA** (*Drakena*) acaulis, foliis pinnatifido-palmatis integerrimis, floribus ovalibus. Lin. Sp. 176. Dwarf Dorstenia with many pointed, hand-shaped, entire leaves, and an oval receptacle to the flowers; banded leaves, whose angles are very acute, and an oblong four-cornered placenta.

The first of these plants was discovered by my late ingenious friend Dr. William Houstoun, near Old Vera Cruz in New Spain. The second was found by the same gentleman, on the rocky grounds about Campeachy. The third sort was found in great plenty in the island of Tobago, by Mr. Robert Millar, surgeon. But the roots of all these species are indifferently brought over, and used in medicine, and for dyeing.

The first sort sends out several leaves from the root, which are about four inches long, and as much in breadth; these are deeply lacinated into five or seven obtuse parts, standing upon foot-stalks near four inches long; they are smooth, and of a deep green. The stalk which supports the placenta arises from the root, and grows near four inches high, upon which the fleshy placenta is vertically placed; this is of an oval form about one inch long, and three quarters broad. Upon the upper surface of this, the small flowers are closely situated, the fleshy part becoming an involucre to them; these are very small, and scarce conspicuous at a distance, being of an herbaceous colour.

The second sort sends out several angular heart-shaped leaves from the root, which have foot-stalks eight or nine inches in length and very slender; the leaves are about three inches and a half long, and almost four broad at their base, the two ears having two or three angles which are acute, and the middle of the leaves are extended and end in acute points like a halbert; these are smooth and of a lucid green; the foot-stalk which sustains the placenta is nine inches long, and about half an inch square, and the upper surface closely set with small flowers like the first.

The third sort sends out leaves of different forms; some of the lower leaves are heart-shaped, having a few indentures on their edges, and ending in acute points, but the larger leaves are deeply cut like the fingers on a hand, into six or seven acute segments. These leaves are five inches long, and six broad in the middle; they are of a deep green, and stand upon long foot-stalks. The placenta is very thick and fleshy, an inch and a half long, and three quarters broad, having four acute corners; these have a number of small flowers, placed on their upper surface like the other species.

These plants are at present very rare in Europe, nor was it known what the plant was, whose roots were imported, and had been long used in medicine in England, until the late Dr. Houstoun informed us: for although father Plumier had discovered one species of this plant, and given the name of Dorstenia to the genus, yet he seems not to have known, that the Contrayerva was the root of that plant.

It will be difficult to obtain these plants, because the seeds are seldom to be found good; nor will they grow, if they are kept long out of the ground; so that the only sure method to obtain them is, to have the roots taken up at the time when their leaves begin to decay, and planted pretty close in boxes of earth, which may be brought very safe to England, provided they are preserved from salt water, and are not over-watered with fresh water in their passage. When the plants arrive, they should be transplanted each into a separate pot filled with fresh earth, and plunged into the bark-stove, which should be kept of a moderate heat; and the plants must be frequently refreshed with water during the summer season; but in winter, when the leaves are decayed, it should be given to them more sparingly. With this management these plants may not only be maintained, but may

may also be increased by parting their roots in the spring, before the plants put out their leaves.

DORYCNIUM. See **LOTUS**.

DOUGLASSIA. See **VOLKAMERIA**.

DRABA. Dillen. Gen. Lin. Gen. Plant. 714. Alysson. Tourn. Inst. R. H. 216. tab. 104.

The **CHARACTERS** are,

The flower hath a four-leaved empalement, which falls off. It hath four petals placed in form of a cross. It hath six stamina, four of which are as long as the empalement, the other two are much shorter and incurved; these are terminated by roundish summits. In the center is situated a bifid germen, supporting a permanent style, crowned by an oblong stigma. The germen afterward becomes a very short capsule with two cells, separated by the swelling style, which is oblique, and longer than the capsule. The valves are parallel to the middle, and divide the lower part of the cell from the upper, which is open, round, concave, and opens oblique, each cell containing a single seed.

This genus of plants is ranged in the first section of Linnæus's fifteenth class, intitled *Tetradynamia Siliculosa*, the flower having four long and two short stamina, and the seeds growing in short capsules or pods.

The **SPECIES** are,

1. **DRABA** (*Alpina*) scapo nudo simplici, foliis lanceolatis integerrimis. Fl. Lapp. 255. *Draba with a single naked stalk, and very entire spear-shaped leaves.* Alysson Alpinum, hirsutum luteum. Tourn. Inst. 217. *Yellow hairy Alpine Madwort.*
2. **DRABA** (*Verna*) scapis nudis, foliis lanceolatis sub incisis. Hort. Cliff. 333. *Draba with naked stalks and cut leaves.* Alysson vulgare, polygoni folio, caule nudo. Tourn. Inst. 217. *Common Madwort with a Knot-grass leaf and naked stalk.*
3. **DRABA** (*Pyrenaica*) scapo nudo, foliis cuneiformibus trilobis. Læff. Lin. Sp. Plant. 642. *Draba with a naked stalk, and wedge-shaped leaves with three lobes.* This is the Alysson Pyrenaicum, perenne, minium, foliis trifidis. Tourn. Inst. 217. *Least perennial Madwort of the Pyrenees with trifid leaves.*
4. **DRABA** (*Muralis*) caule ramoso, foliis cordatis dentatis amplexicaulibus. Prod. Leyd. 33. *Draba with a branching stalk, and heart-shaped indented leaves embracing the stalks.* Alysson veronicae folio. Tourn. Inst. 217. *Madwort with a Speedwell leaf.*
5. **DRABA** (*Polygonifolia*) caule ramoso, foliis ovatis sessilibus dentatis. Lin. Sp. Plant. 643. *Draba with a branching stalk, and oval indented leaves growing close to the branches.* Alysson Alpinum, polygoni folio incano. Tourn. Inst. R. H. 217. *Alpine Madwort with a hoary Knot-grass leaf.*
6. **DRABA** (*Incana*) foliis caulinis numerosis incanis, siliculis oblongis. Flor. Succ. 526. *Draba with many hoary leaves on the stalks, and oblique pods.* Lunaria siliqua oblonga intorta. Tourn. Inst. 219. *Moonwort with an oblong intorted pod.*

The first sort grows naturally on the Alps, and other mountainous parts of Europe; this is a very low plant, which divides into small heads like some sorts of Houseleek, and from thence it was titled *Sedum Alpinum* &c. or *Alpine Houseleek*. The leaves are short, narrow, and very hairy; from each of these heads come out a naked flower-stalk an inch and a half high, terminated by loose spikes of yellow flowers, having four obtuse petals placed in form of a cross; when they fade they are succeeded by triangular or heart-shaped pods, which are compressed, and inclose three or four roundish seeds. It flowers in March, and the seeds ripen the beginning of June.

This plant is easily propagated by parting of the heads; the best time for doing of this is in autumn, because it shoots up to flower very early in the spring. It should have a moist soil and a shady situation, where it will thrive and flower annually. It requires no other culture but to keep it clean from weeds.

The second sort is an annual plant, which grows naturally upon walls and dry banks in many parts of England, so is never cultivated in gardens. This flowers in April, and the seeds ripen in May.

The third sort grows naturally on the Alps, and other mountainous parts of Europe. This is a low perennial plant, which seldom rises more than two inches high; it has a shrubby stalk, which divides into many small heads like the first sort. The leaves are small, some of them are winged, having five short narrow lobes, placed on a midrib, others have but three. The flowers come out in clusters, sitting close to the leaves. They are of a bright purple colour, and appear early in the spring. This is a perennial plant, which may be propagated by parting of the heads in the same manner as the first, and requires the same treatment.

The fourth sort grows naturally in shady woods in many parts of Europe, and is but seldom kept in gardens, unless for the sake of variety. It is an annual plant, rising with an upright branching stalk about ten inches high, garnished with heart-shaped indented leaves, which embrace the stalks with their base. The stalks are terminated by loose spikes of white flowers, which appear the beginning of May; in June the seeds ripen, and the plants soon after decay. If the seeds are permitted to scatter, the plants will come up without trouble. It must have a shady situation, and delights in a moist soil.

The fifth sort is an annual plant, which grows in shady woods in the northern parts of Europe. This is like the former sort, but the leaves are larger, rounder, and do not embrace the stalks; they are also hairy, and the flowers are yellow. If the seeds of this are permitted to scatter, the plants will maintain themselves if they have a shady situation.

The sixth sort rises with an upright stalk about a foot high, the lower part being very closely garnished by oblong hoary leaves, which are indented on their edges. The upper part of the stalk puts out two or three short branches; these are almost naked of leaves, as is also the upper part of the stalk. The flowers come out loosely on the top of the stalk; they are composed of four small white petals placed in form of a cross, which are succeeded by oblong pods, which are twisted, containing three or four roundish compressed seeds. It flowers in June, and the seeds ripen in July. This grows naturally in the north of England and in Wales.

This plant seldom continues more than two years, but if the seeds are sown in autumn in a shady border, the plants will come up in the spring; or where the seeds are permitted to scatter, the plants will rise without any trouble.

DRACO ARBOR. See **PALMA**.

DRACO HERBA. [i. e. Dragon's-wort.] Tarra- gon, vulgò. See **ABROTANUM**.

DRACOCEPHALUM. Lin. Gen. Plant. 648. *Dracocephalon.* Tourn. Inst. R. H. 181. tab. 83. [of δράκων, a dragon, and κεφαλή, a head.] i. e. Dragon's-Head.

The **CHARACTERS** are,

The flower hath a short permanent empalement of one leaf, which is tubulous. It hath one ringent petal, with a tube the length of the empalement, with large oblong inflated chaps. The upper lip is obtuse and arched, the under lip is trifid; the two side segments are erect, the middle turns downward and is indented. It hath four stamina situated near the upper lip, two being shorter than the other, and are terminated by heart-shaped summits. It hath a four-parted germen, supporting a slender style, situated with the stamina, and crowned by a bifid reflexed stigma. The germen afterward becomes four oval oblong seeds, inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, intitled *Didynamia Gymnospermia*, the flower having two long and two shorter stamina, and the seeds are naked.

The **SPECIES** are,

1. **DRACOCEPHALUM** (*Virginianum*) floribus spicatis foliis lanceolatis serratis. Lin. Sp. 828. *American Dragon's-Head with single leaves and spiked flowers.* *Dracocephalon Americanum.* Breyn. Prod. 1. 34. *American Dragon's-Head.*

2. DRACOCEPHALUM (*Canariense*) floribus spicatis, foliis compositis. Lin. Hort. Cliff. 308. *Dragon's-Head with spiked flowers and compound leaves.* Moldavica Americana trifolia odore gravi. Tourn. Inst. 184. *Three-leaved American Balm, having a strong smell, commonly called Balm of Gilead.*
3. DRACOCEPHALUM (*Moldavica*) floribus verticillatis, bracteis lanceolatis ferraturis capillaceis. Lin. Hort. Cliff. 308. *Dragon's-Head with flowers growing in whorls, and spear-shaped bractes.* Moldavica betonicae folio, flore caeruleo. Tourn. Inst. R. II. 184. *Moldavian Balm with a Betony leaf and blue flower.*
4. DRACOCEPHALUM (*Ocymifolia*) floribus verticillatis, foliis floralibus orbiculatis. Lin. Hort. Cliff. 308. *Dragon's-Head with flowers growing in whorls, and the upper leaves round.* Moldavica orientalis minima ocymifolio, flore purpurascens. Tourn. Cor. 11. *Lesser Eastern Moldavian Balm with a Willow leaf and a bluish flower.*
5. DRACOCEPHALUM (*Canescens*) floribus verticillatis, bracteis oblongis, ferraturis spinosis, foliis tomentosis. Hort. Upsal. 166. *Dragon's-Head with flowers growing in whorls, and the little leaves under the flowers sawed, ending in spines, and woolly leaves.* Moldavica orientalis betonicae folio, flore magno violaceo. Tourn. Cor. 11. *Eastern Moldavian Balm with a Betony leaf, and a large blue flower.*
6. DRACOCEPHALUM (*Nutans*) floribus verticillatis, bracteis oblongis ovatis integerrimis, corollis majusculis nutantibus. Hort. Upsal. 167. *Dragon's-Head with flowers growing in whorls, the small leaves under the flowers are oblong, entire, and hanging flowers much larger than the empalement.* Moldavica betonicae folio, floribus minoribus caeruleis pendulis. Amman. Ruth. 44. *Moldavian Balm with a Betony leaf, and smaller blue pendulous flowers.*
7. DRACOCEPHALUM (*Thymiflorum*) floribus verticillatis, bracteis oblongis integerrimis, corollis vix calyce majoribus. Hort. Upsal. 167. *Dragon's-Head with flowers growing in whorls, the small leaves are oblong, entire, and the flowers equal with the empalement.* Moldavica betonicae folio, floribus minimis pallide caeruleis. Amman. Ruth. 46. *Moldavian Balm with a Betony leaf, and very small blue flowers.*
8. DRACOCEPHALUM (*Peltatum*) floribus verticillatis, bracteis orbiculatis ferratociliatis. Hort. Upsal. 166. *Dragon's-Head with flowers growing in whorls, oval bractes and very narrow spear-shaped leaves.* Moldavica orientalis, foliis ovatis, flore parvo caeruleo. Tourn. Cor. 11. *Eastern Moldavian Balm with a Willow leaf, and a small blue flower.*
9. DRACOCEPHALUM (*Grandiflorum*) floribus verticillatis, foliis ovatis inciso-crenatis, bracteis lanceolatis integerrimis. Lin. Sp. Plant. 595. *Dragon's-Head with flowers growing in whorls, oval leaves which are cut and crenated, and spear-shaped bractes which are entire.*

The first sort is a native of North America, where it grows in the woods, and by the sides of rivers. This rises with an upright stalk, which is four-cornered, near three feet high, garnished with spear-shaped leaves about three inches long, and half an inch broad, sitting close to the stalk; they are sawed on their edges, and are placed opposite at each joint, sometimes there are three leaves standing round at the same place. The flowers are purple and grow in spikes on the top of the stalks, so make a pretty variety among other hardy plants, especially if the plants are strong and vigorous. This is a perennial plant, which will live in the open air, but requires a moist soil, or should be duly watered in dry weather, otherwise the leaves will shrink, and the flowers will make little appearance. This may be allowed a place in the shady borders of a garden, since it will not ramble, or take up much room. It flowers in July, and continues until the middle or end of August, and may be propagated by parting of the roots in autumn.

The second sort is a native of the Canary Islands, and hath been long an inhabitant in the gardens; it is usually called by the gardeners Balm of Gilead, from

the strong resinous scent which the leaves emit on being rubbed. This is a perennial plant, which rises with several square stalks to the height of three feet or more, becoming ligneous at their lower parts, and are garnished with compound leaves at each joint, which are placed opposite; these have three or five lobes, which are oblong, pointed, and sawed on their edges. The flowers come out in short thick spikes on the top of the stalks; they are of a pale blue colour, and are succeeded by seeds, which ripen very well in England. This plant continues producing flowers most part of summer; it is usually kept in green-houses; but in mild winters the plants will live abroad, if they are planted in warm borders; and those plants which are kept in pots, will thrive much better when they are sheltered under a frame, than if placed in a green-house, where the plants are apt to draw up weak, for they should have as much free air as possible in mild weather, and only require to be sheltered from severe frost. This may be propagated by seeds, which, if sown in autumn, will more certainly grow, than those which are sown in the spring; but if these are sown in pots, they must be sheltered under a frame in the winter, and if the plants do not come up the same autumn, they will arise in the spring; but if the seeds are sown in the full ground, it should be in a warm border; and in hard frost they should be sheltered, otherwise the young plants will be destroyed. The plants may also be propagated by cuttings; which, if planted in a shady border any time in summer, will very soon take root, and furnish plenty of rooted plants.

The third sort is a native of Moldavia; this has been long preserved in curious gardens. It is an annual plant, which rises with branching stalks a foot and a half high, garnished with oblong leaves, which are placed opposite, and are deeply sawed on their edges. The flowers come out in whorls round the stalks at every joint; these are blue, and appear in July, continuing to the middle of August, and the seeds ripen in September. The plants have a strong balsamic odour, which is to some persons very agreeable: the seeds should be sown in small patches in the spring, upon the borders where they are to remain, and when the plants come up, they should be thinned where they grow too near together, and kept clear from weeds, which is the only culture they require. Of this there is a variety with white flowers, which is pretty common in the gardens; this only differs from the other in the colour of the flowers, but yet these constantly retain their difference from seeds.

The fourth sort was discovered by Dr. Tournefort in the Archipelago, who sent the seeds to the royal garden at Paris, which have since been communicated to many curious gardens in Europe; this rises with upright stalks about a foot high, which seldom put out branches; these are garnished with long narrow leaves, which are entire, placed opposite at each joint, where the flowers come out in whorls, almost the whole length of the stalks; these are of a pale blue, and appear about the same time as the former; this sort has very small flowers, which make no great appearance, therefore is seldom cultivated, except in botanic gardens for the sake of variety.

The fifth sort was discovered by Dr. Tournefort in the Levant; this hath hoary square stalks, which rise a foot and a half high, putting out two or three side branches, garnished with hoary leaves near two inches long, and half an inch broad, a little indented on their edges; they are placed opposite at the joints, just under the whorls of flowers, which sit close to the stalk; these are larger than those of the other species, and are of a fine blue colour, which between the hoary leaves of the plant, make a pretty appearance. It flowers and seeds about the same time as the former sorts; this is generally treated as an annual plant, like the former sorts, but the roots of this will live two years if they are in a dry soil. There is a variety of this with white flowers, the seeds of which generally produce the same coloured flowers.

The sixth sort grows naturally in Siberia, from whence the seeds were sent to the imperial garden at Peterburgh, and the late Dr. Amman, who was professor of botany, sent me the seeds. This is an annual plant, from whose roots come out many square weak stalks, which grow about nine inches long; these are at the bottom garnished with oval spear-shaped leaves about two inches long, and one inch and a quarter broad, standing opposite upon pretty long foot-stalks, and are crenated on their edges. The upper part of the stalks have smaller leaves, which sit close at the joints, from whence come out the flowers in whorls; they are of a deep blue colour, and hang downward; these appear at the same time with the former, and the seeds ripen in autumn.

The seventh sort grows also in Siberia, the seeds of this were sent me with the former. It hath square stalks, which rise a foot and a half high; the lower leaves are very like those of Betony, and stand upon very long foot-stalks. The upper leaves are small, and sit closer to the stalks. The flowers come out in whorls at every joint; these are very small, and of a pale purple or blue colour, so make little appearance, but it is preserved in some gardens for the sake of variety.

The eighth sort grows naturally in the Levant, from whence Dr. Tournefort sent the seeds to the royal garden at Paris. This is an annual plant, which rises with a square stalk about a foot high, sending out two small side branches from the lower part. The leaves are spear-shaped, and crenated on their edges; they are placed opposite, and stand on foot-stalks. The flowers are small, of a purplish colour, and come out in whorls round the stalks, having two roundish-small leaves (called bractæ) immediately under them, which are sawed on their edges, each serrature ending with a long hair. This sort flowers and seeds at the same time as the former.

All these sorts are propagated by seeds, which may be sown either in the spring or autumn, in the places where the plants are to remain, and will require no other treatment than the third sort.

DRACONTIUM. Lin. Gen. Plant. 916. Dracunculus. Tourn. Inst. R. H. 160. tab. 70. Dragon; in French, *Serpentaire*.

The CHARACTERS are,

It hath a single cylindrical spadix (or stalk) on the upper part of which the parts of fructification are disposed in a singular manner. The flowers have no empalement, but have five oval concave petals, which are equal; they have seven narrow depressed stamina the length of the petals, terminated by oblong, four-cornered, twin summits, which stand erect; they have an oval germen, supporting a taper style, crowned by a three-cornered stigma. The germen afterward becomes a roundish berry, inclosing several seeds; these are all inclosed in a large fleshy spathe (or sheath) opening with one valve.

This genus of plants is ranged in the seventh section of Linnaeus's twentieth class, intitled Gynandria Polyandria. This class and section contains the plants which have male and female flowers joined in the same spike, and the male flowers have several stamina.

The SPECIES are,

1. **DRACONTIUM** (*Pertusum*) foliis pertusis, caule scandente. Lin. Sp. Plant. 968. *Dragon with leaves having holes, and a climbing stalk.* Arum hederaceum, amplis foliis perforatis. Plum. Amer. 40. tab. 56. *Climbing Arum with large perforated leaves.*
2. **DRACONTIUM** (*Polyphyllum*) scapo brevissimo, petiolo radicato, lacero, foliolis tripartitis, laciniis pinnatifidis. Hort. Cliff. 434. *Dragon with a very short stalk, the foot-stalk cut, and the small leaves divided into three parts, which terminate in many points.* Arum polyphyllum, caule scabro punicante. Par. Bat. 93. *Many leaved Arum with a rough purple stalk.*
3. **DRACONTIUM** (*Spinosum*) foliis sagittatis, pedunculis petiolisque aculeatis. Flor. Zeyl. 328. *Dragon with arrow-pointed leaves, whose foot-stalks have spines.* Arum Zeylanicum spinosum, sagittæ foliis. Par. Bat. 75. *Prickly Arum of Ceylon with arrow-pointed leaves.*

4. **DRACONTIUM** (*Camtschatcense*) foliis lanceolatis. Amoen. Acad. 2. p. 360. *Dragon with spear-shaped leaves.*

The first sort grows naturally in most of the islands in the West-Indies. This hath slender jointed stalks, which put out roots at every joint, that fasten to the trunks of trees, walls, or any support which is near them, and thereby rise to the height of twenty-five or thirty feet. The leaves are placed alternately, standing upon long foot-stalks; they are four or five inches long, and two and a half broad, having several oblong holes in each, which on the first view appears as if eaten by insects, but they are natural to the leaves. The flowers are produced at the top of the stalk, which always swells to a larger size in that part than in any other; these are covered with an oblong spathe (or hood) of a whitish green colour, which opens longitudinally on one side, and shews the pistil, which is closely covered with flowers, of a pale yellow, inclining to white. When this plant begins to flower, it seldom advances farther in height, so that these seldom are more than seven or eight feet high; but the leaves are much larger on these, than those of the plants which ramble much farther.

This plant is easily propagated by cuttings, which, if planted in pots filled with poor sandy earth, and plunged into a hot-bed, will soon put out roots, if they had none before; but there are few of the joints which have not roots: the plants are tender, so will not live in the open air in England, therefore the pots should be placed near the walls of the hot-house, against which the plants will climb, and fasten their roots into the wall, and thereby support the stalks. They should have but little water given them in the winter, but in warm weather it must be given them three or four times a week, and in the summer the free air should be admitted to them in plenty. The plants have no particular season of flowering, for they sometimes flower in autumn, and at other times in the spring, but they do not ripen their seeds in England.

The second sort grows naturally in several of the islands of America. I received roots of this from Barbuda. This hath a large knobbed irregular root, covered with a rugged brown skin. The stalk rises about a foot high, is naked to the top, where it is garnished with a tuft of leaves, which are divided into many parts. The stalk is smooth, of a purple colour, but is full of sharp protuberances of different colours, which shine like the body of a serpent. The spadix (or stalk) of the flower rises immediately from the root, and is seldom more than three inches high, having an oblong swelling hood at the top, which opens lengthways, shewing the short, thick, pointed pistil within, upon which the flowers are closely ranged.

This sort is tender, so requires a warm stove to preserve it in England. The roots must be planted in pots filled with light kitchen-garden earth, and plunged into the tan-bed in the stove, where they should constantly remain; in the winter they must be watered very sparingly, but in warm weather, when the plants are in vigour, they must be often refreshed, but it should not be given them in too great quantities; with this management the plants will flower, but their roots do not increase here.

The third sort grows naturally in the island of Ceylon, and in several parts of India; this hath an oblong thick root, full of joints, from which arise several leaves, shaped like those of the common Arum, but their foot-stalks are covered with rough protuberances. The stalk which supports the flower is short, and set with the like protuberances; and at the top is a hood, or spathe, about four inches long, as thick as a man's finger, which opens longitudinally, and exposes the pistil, which is set with flowers. This is a tender plant, and requires the same treatment as the former sort.

The fourth sort hath roots like the common Arum, from which come out several spear-shaped leaves, standing each upon a separate foot-stalk, arising immediately

D R O

mediately from the root, as those of the common *Arum*. This hath not yet flowered in England, so I can give no further account of it. This grows naturally in Siberia, so requires a shady situation, and will bear the greatest cold of this country.

These plants are preserved in the gardens of the curious in England and Holland, more for the sake of variety than for beauty; for except the first sort, there is not any of them which make much appearance; that indeed may be suffered to have a place against the wall of the stove, over which it will spread, and cover the nakedness of the wall; and the leaves remaining all the year, which are so remarkably perforated, make a singular appearance.

All the other sorts of Dragon are tender plants, so will not live in this country, unless they are preserved in the warmest stoves; the several American sorts grow naturally in the woods in Jamaica, and other hot parts of America; the climbing sorts twist themselves round the trunks of trees, into which they fasten their roots, which are sent forth from their joints, and rise to the height of thirty or forty feet. These climbing sorts are easily propagated by cuttings, which, being very succulent, may be brought over to England in a box of dry hay, if they are packed up separate, so as not to injure each other by the moisture, which is apt to flow out at the part where they are cut off, which may occasion a fermentation, and thereby rot the cuttings. When the cuttings arrive, they should be planted in small pots filled with light fresh earth, and plunged into a hot-bed of tanners bark, being very careful not to let them have too much moisture until they have taken root, lest it rot them: when they have taken root, they must be frequently refreshed with water; and when they are grown pretty large, they should be placed in the bark-bed in the stove, where they must be placed near some strong plants, to which they may fasten themselves, otherwise they will not thrive; for though they will send forth roots at their joints, which will fasten to the mortar of the stove, when placed against the wall, yet they will not thrive near so well as against a strong plant, which will afford them nourishment.

The other sorts are propagated by offsets from their roots; these may be procured from the countries of their growth, and should be planted in tubs of earth, about a month before they are put on board the ship to transport them; these tubs should be placed in a shady situation until they have taken root. In their passage great care should be had to keep them from salt water, as also not to let them have too much water given them; for if they have a little water once or twice a week at most, while they are in a hot climate, and when they are come into a cooler climate, once in a fortnight, this will be sufficient for them; and it should be done sparingly, lest it rot them; for if the tops of the plants should decay for want of water in their passage, if the roots are not rotted, they will soon recover with proper care.

When the plants arrive, they should be transplanted into pots filled with light fresh earth, and plunged into a hot-bed of tanners bark, and gently watered until they have taken good root, after which time they will require to be frequently refreshed with water; but as their stems are very succulent, they must not have too much moisture. These plants should be constantly kept in the stove, where, in hot weather, they should have fresh air admitted to them; but in winter they must be kept very warm, otherwise they cannot be preserved in this country.

These plants will rise to the height of three, four, or five feet, and will afford a very agreeable variety amongst other tender exotic plants in the stove.

DRACUNCULUS PRATENSIS. See *ACHILLEA*.

DRAGON. See *DRACONTIUM*.

DROSER A. *Ros Solis*, or Sun-dew.

We have two or three species of this plant, which grow naturally upon bogs in many parts of England,

D U N

and there are three or four other sorts, which are natives of warmer countries; but as these cannot be cultivated in gardens, unless where there are bogs, it would be needless to describe them.

The common round-leaved sort is used in medicine, so is gathered by the herb-folks who supply the markets.

DRYAS, Cinquefoil Aven.

There are two species of this genus, which grow naturally in Scotland and Ireland, upon mountainous places, where the soil is wet; one of them hath five petals to the flower, and winged leaves, the other hath eight petals to the flower, and simple leaves; but as neither of the plants make much appearance, they are rarely preserved except in some botanic gardens for variety.

DULCAMARA. See *SOLANUM*.

DUNGS are designed to repair the decays of exhausted or worn-out lands, and to cure the defects of land, which are as various in their qualities as the dungs are, that are used to meliorate and restore them: some lands abound too much in coldness, moisture, and heaviness; others again are too light and dry, and so, to answer this, some dungs are hot and light, as that of sheep, horses, pigeons, &c. others again are fat and cooling, as that of oxen, cows, hogs, &c. And as the remedies that are to be used must be contrary to the distempers they are to cure, so the dung of oxen, cows, and hogs, must be given to clean, dry, light earths, to make them fatter and closer, and hot and dry dungs to meliorate cold, moist, and heavy lands.

There are two peculiar properties in dungs, the one is to produce a certain sensible heat, capable of producing some considerable effect, which properties are seldom found but in the dung of horses and mules, while it is newly made, and a little moist; the other property of dung is, to fatten the earth and render it more fruitful.

The dung of horses and mules is of admirable use in gardens in the winter time, because it then animates and enlivens all things; and, in some measure, supplies the office which is performed by the heat of the sun in the summer time, affording us all the novelties of the spring, as Asparagus, Cucumbers, Radishes, sallads, &c. Horse dung is the best improvement for cold jejune lands that we can procure in any quantity; but yet horse dung being used alone, or when it is too new, is frequently prejudicial to some plants; and if it be spread thin over lands in the summer time, it is of very little service, because the sun, drawing out all the virtue and goodness of it, renders it little better than thatch or dry straw; and though too much of it can scarcely be used in a kitchen-garden for Cabbages, Cauliflowers, and all other plants that grow there, and require abundance of nourishment; yet may it be a fault to lay too much of it on corn-lands, because it produces abundance of straw.

In very cold moist land, I have frequently seen new horse dung buried as it came from the stable, and always observed that the crops have succeeded better, than where the ground was dressed with very rotten dung.

Horse dung being of a very hot nature, is best for cold lands, and cow dung for hot lands; and being mixed together, may make a very good manure for most sorts of soil, and for some they may be mixed with mud.

Sheeps dung and deers dung differ not much in their quality, and are esteemed by some the best of dungs for cold clays. Some recommend them to be beat into powder, and spread very thin over autumn or spring crops, about four or five loads to an acre, after the same manner as ashes, malt dust, &c. are strewed.

This I have seen practised upon corn, and also upon grass land, to great advantage for the first year; but these light dressings do not last long, therefore require to be often repeated.

In

In Flanders and other places, they house their sheep at nights in places spread with clean sand, laid about five or six inches thick, which, being laid on fresh every night, is cleared out once a week; this mixture of sand and dung makes an excellent dressing for strong land, for the dung and urine of the sheep is a very rich manure, bears a considerable price, and is an excellent manure for all stiff cold land: and Mr. Quinteney is of opinion, that it is the greatest promoter of fruitfulness in all sorts of ground.

Others recommend hogs dung as the fattest and most beneficial of all sorts of dungs; and say, that one load of it will go as far as two loads of other dung, and that it is the best of all dungs for fruit-trees, especially for Pear and Apple-trees in a light soil, and a very rich dung for grass. I have often used this dung to fruit-trees when it was well rotted, and have found it the most beneficial to them of any manure.

The dung of pigeons, hens, and geese, are great improvers of meadow or corn land, the first of these being the best superficial improvement that can be laid on meadow or corn land: but before it is used, it ought to have lain abroad out of the dove-house some time, that the air may have a little sweetened it, and mollified the fiery heat that is in those dungs.

Especially it is good for cold, wet, clayey lands; but it ought to be dried before it be strewed, because it is naturally apt to clod in wet; and it should be mixed with earth or sand to keep it from clinging together, that it may be strewed thin, being naturally very hot and strong.

Some recommend the dung of pigeons, and also of other fowls, as the best manure for Asparagus, Strawberries, or any sorts of flowers; but this should be rotted and well mixed with the earth, before it is used to flowers.

Monsieur Gentil approves of pigeons dung, as being good for such trees whose leaves are apt to turn yellow, if they grow in free soils that are rather cold than hot, provided the heat of it has been abated by lying two or three years in the dunghill; but this should be applied in autumn, and in small quantities.

This being spread about an inch thick at the foot of a tree, whose leaves are yellow, and being left there till March, he recommends as very useful in cold and moist soils.

The dung of poultry being hot and full of salts, tends much to facilitate vegetation, and is abundantly quicker in its operation than the dung of animals which feed on herbs.

Sir Hugh Plat says, one load of grain will enrich ground more than ten loads of common dung; which if it be true, it is rational to suppose, that if simple grain, by only infusion in the mixture of composts, has a very good effect, it will be more powerful when it has passed through the bodies of animals.

Human dung is a great improver of all cold sour lands, and especially if it be mixed with other earths or dungs to give it a fermentation.

But there is not any sort of manure equal to the cleansing of London streets, for all stubborn clayey soils; the parts of which will be better separated, and in a much less time, with this manure, than with any other compost whatever; and where it can be obtained, is extremely well worth procuring, either for corn, grass, or garden land.

DURANTIA. Lin. Gen. Plant. 704. Castorea. Plum. Nov. Gen. 30. tab. 17.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is erect, and cut into five acute segments at the top, and sits upon the germen; the flower is of the ringent kind, with one petal, having a long tube, which opens at the top in two lips; the upper lip is oval, erect, and concave; the under is divided into four equal segments, which are round. It hath four short stamina, situated in the bottom of the tube, the two middle being a little shorter than the other, terminated by prostrate summits; the germen which is situated under the flower, supports a long

slender style, crowned by a headed stigma. The germen at terward becomes a globular berry, terminated by three acute points, having one cell inclosing four angular seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two shorter stamina, and the seeds being included in a capsule.

The title which was first given by father Plumier to this genus, was Castorea, in memory of Castor Durant, a physician of Rome, who published a history of plants in Italian, which was printed at Rome in 1585. Dr. Linnæus has now altered the title of the genus, and instead of the christian name, he has given it the surname of the same person.

The SPECIES are,

1. DURANTIA (*Plumeiri*) spinosa. Lin. Sp. Plant. 637. *Prickly Durantia*. Castorea repens spinosa. Plum. Nov. Gen. 30. *Creeping prickly Castorea*.
2. DURANTIA (*Racemosa*) inermis. Lin. Sp. Plant. 637. *Durantia without thorns*. Castorea racemosa flore cæruleo, fructu croceo. Plum. Nov. Gen. 30. *Branching Castorea with a blue flower and Saffron-coloured fruit*.

3. DURANTIA (*Erecta*) caule erecto spinoso, foliis ovatis integerrimis, floribus racemosis. *Durantia with an upright prickly stalk, oval entire leaves, and flowers growing in long bunches*. Jasminum folio integro, obtuso, flore cæruleo racemoso, fructu flavo. Sloan. Cat. Jam. 169. *Jasmine with entire obtuse leaves, blue flowers growing in bunches, and a yellow fruit*.

The first sort hath many trailing branches, which are armed with hooked thorns at every joint, and are garnished with oblong leaves, which are placed without order, and are slightly sawed on their edges; the flowers come out from the side of the stalks in pretty long bunches, like those of the common Currant; they are of a pale bluish colour, and succeeded by brown berries not unlike the fruit of the Hawthorn; these have one cell, and inclose four angular seeds.

The second sort hath a branching woody stalk, which rises seven or eight feet high; the branches are garnished with oval spear-shaped leaves three inches long, and one and a half broad in the middle; they are sawed on their edges, of a lucid green colour, and stand opposite. The flowers are produced in long bunches at the end of the branches; these are blue, and succeeded by pretty large, round, yellow berries, which contain four angular seeds.

The third sort rises with a strong woody stem to the height of ten or twelve feet, covered with a white bark, dividing into many branches, which are armed with sharp thorns on their side; these are garnished with oval stiff leaves one inch long, and three quarters broad. The flowers come out in long bunches from the end of the branches, which are blue, and are succeeded by small, round, yellow berries, which contain four angular seeds. I received this from the late Dr. Houstoun, who found it growing in Jamaica.

The plants are natives of warm countries, so they require a stove to preserve them in England; they are propagated by seeds, which should be sown in small pots, and plunged into a hot-bed of tanners bark; and when the plants are fit to remove, they must be planted each into a separate small pot filled with light earth, and plunged into the hot-bed again, observing to shade them till they have taken new root, then they must be treated in the same manner as other plants from the same country.

The second sort may be propagated by cuttings, which may be planted in any of the summer months; but these should be plunged into a moderate hot-bed, and shaded from the sun till they have taken root, then they may be treated in the same manner as the seedling plants. This sort is not so tender as the other two, so may be placed in the open air in summer; and if they are kept in a moderate temperature of warmth in the winter, they will thrive better than in great heat. I kept some of the plants of this sort three winters, in a dry warm glass case without fires,

and they have succeeded pretty well; but the winter 1762 proving severe, caused their leaves to fall, but since they have put out again very well.

DWARF-TREES. These were formerly in much greater request than they are at present; for though they have many advantages to recommend them, yet the disadvantages attending them greatly over-balance; and since the introducing of espaliers into the English gardens, Dwarf-trees have been in little esteem for the following reasons:

1st, The figure of a Dwarf-tree is very often so much studied, that, in order to render the shape beautiful, little care is taken to procure fruit, which is the principal design in planting these trees.

2dly, The branches being spread horizontally near the surface of the ground, render it very difficult to dig or clean the ground under them.

3dly, Their taking up too much room in a garden (especially when they are grown to a considerable size) so that nothing can be sown or planted between them.

4thly, These trees spreading their branches near the ground, continually shade the surface of the earth; so that neither the sun nor air can pass freely round their roots and stems, to dissipate noxious vapours; whereby the circumambient air will be continually replete with crude rancid vapours, which, being drawn in by the fruit and leaves, will render its juices crude and unwholesome, as well as ill tasted.

It is also very difficult to get to the middle of these Dwarf-trees in the summer, when their leaves and fruit are on the branches, without beating off some of the fruit, and breaking the young shoots; whereas, the trees on an espalier can at all times be come at on each side, to tie up the new shoots, or to displace all vigorous ones, which, if left on, would rob the trees of their nourishment.

Add to this, the fruit-buds of all sorts of Pears and Apples, and most sorts of Plumbs and Cherries, are first produced at the end of the former year's shoot, which must be shortened in order to keep the Dwarfs to their proper figure, so that the fruit-buds are cut off, and a greater number of branches are obtained, than can be permitted to stand; so that all those sorts of fruit-trees, whose branches require to be trained at their full length, are very improper to train up as Dwarfs; and the Peaches and Nectarines which will bear amputation, are too tender to be trained so in this country.

These evils being entirely remedied by training the trees to an espalier, hath justly gained them the preference; however, if any one has a mind to have Dwarf-trees, notwithstanding what has been said, I shall lay down a few rules for their management.

If you design to have Dwarf Pear-trees, you should bud or graft them on Quince stocks; but as many sorts of Pears will not thrive if they are immediately budded or grafted on Quince stocks, so some of those sorts which will take freely, should be first budded on the Quince stocks; and when these have shot, the sorts you intend to cultivate, should be budded into

these; for free stocks are apt to make them shoot so vigorously, as not to be kept within bounds. These grafts or buds should be put in about four or six inches above the surface of the ground, that the heads of the trees may not be advanced too high; and when the bud or graft has put out four shoots, you should stop the end of the shoots, to force out lateral branches.

Two years after budding, these trees will be fit to transplant where they are to remain; for though many people chuse to plant trees of a greater age, yet they seldom succeed so well as young ones. The distance these trees should be planted is twenty-five or thirty feet asunder, for less will not do if the trees thrive well. The ground between them may be cultivated for kitchen-garden herbs while the trees are young, but you should not sow or plant too near their roots.

In order to train your trees regularly, you should drive stakes into the ground round the tree, to which the branches should be fastened down with liss in a horizontal position; for if they are suffered to grow perpendicularly while young, they cannot be afterwards reduced without great violence to any tolerable figure. The necessary directions to be afterwards followed are, not to suffer any branches to cross each other; and always in shortening any shoots be sure to leave the uppermost eye outwards, whereby the hollowness in the middle of the tree will be better preserved; and be careful to rub off all perpendicular shoots in the middle of the trees, as soon as they are produced. The other necessary rules you will find under the article of PRUNING.

The sorts of Pears which do best in Dwarfs, are all summer and autumn fruits; for winter Pears are not worth planting in Dwarfs, they seldom bearing well, nor are ever well tasted, and commonly are very stony, because they are commonly grafted on Quince stocks.

Apples are also planted in Dwarfs, most of which are now budded or grafted on Paradise stocks; but as these are for the most part of a short duration, they are not profitable, and are fit only for small gardens as a matter of curiosity, producing fruit sooner, and in greater plenty, than when they are upon Crab or Apple stocks.

The distance these trees should be planted, if on Paradise stocks, should be six or eight feet, and upon Dutch stocks eighteen or twenty; but if on Crab stocks, twenty-five or thirty feet asunder each way. The management of these being the same with Pears, I need not repeat it.

Some persons also plant Apricots and Plumbs for Dwarfs, but these seldom succeed well, as being of a tender constitution; and those which will produce fruit on Dwarfs, are much more likely to do so when trained on an espalier, where they can be much better managed; and therefore I judge it much the better method, as being more certain, and the trees will make a better appearance.

E.

E A R

EARTH is the principal matter whereof our globe consists; the character of which, according to Dr. Boerhaave, is, that it is a fossil body, neither dissoluble by fire, water, nor air; that it is insipid and transparent; more fusible than stone; still friable, and containing usually a share of fatness. There is no such thing as a strictly simple earth. Mr. Boyle says, that it doth not appear, that nature, any more than art, affords an elementary earth; at least, some which appear of the simplest sorts are found, upon examination, to have qualities not ascribed to pure earth.

Of such earths some are simple and immutable, as chalk, pumice, and rotten stone; others compound and fatty; of which kind are all boles, red, white, and brown; fullers earth, and divers kinds of medicinal earths, as the Cretica, Hungarica, Lemnian earth, and others.

Which earth are all resolvable into oil, a little acid salt, &c. and a calx, which is the basis, or the earth properly so called.

Sand is by naturalists generally ranked as a species of earth, though not very properly; in that sands, strictly speaking, are a sort of crystals, or little transparent pebbles, and are calcinable; and, by the addition of a fixed alkaline salt, fusible and convertible into glass.

The fat earth is rendered fertile by the means of sand, and becomes fit to feed and nourish vegetables, &c. for pure earth is liable to coalesce into a hard coherent mass, as in clay; and earth thus embodied, and as it were glued together, would be very unfit for the nourishment of plants.

But if hard sand, i. e. crystals, which are indissoluble in water, and still retain the same figure, be intermixed with such earth, they will keep the pores of the earth open, and the earth itself loose and incompact, and by that means give room for the juices to move, ascend, &c. and for plants to be nourished thereby.

Thus a vegetable, being planted either in the sand alone, or in the fat glebe and earth alone, receives no growth or increment, but is either starved or suffocated; but mix the two, and the mass becomes fertile.

In effect, by means of sand the earth is rendered, in some measure, organical; pores and interstices being hereby maintained or preserved, something analogous to vessels is effected, by which the juices of the earth may be conveyed, prepared, digested, circulated, and at length excerned and thrown off in the roots of plants.

The earth is made up of two parts; the first the containing part, i. e. the body, bed, or couch: the second the part contained, and those are the nitrous or sulphureous particles, or prolific salts. The first is a lifeless inanimate mass, and is only the receptacle of the other; for the earth, considered simply, and abstracted from the before-mentioned nitrous and prolific salts, is a lifeless, dead, and inanimate mass; but by the co-operation of water, sun, and air, is put into motion, and promotes the work of vegetation: but if it were stript of those prolific salts and spirituous particles, would produce no manner of plant, herb, &c. that should be planted or sown in it.

E A R

These nitrous particles, or prolific salts, are of various and different qualities; and according as the earth is more or less stored with all or some of them, it is more or less productive; and according as it abounds with some of them more than others, differing from one another in contexture, it constitutes the different species or kinds of soils adapted to the propagation of different plants, the pores of whose roots are formed to receive, and whose nature is to attract, those salts that are congenial to them.

Some distinguish earths into three classes, sand, loam, and clay, as those upon one or other of which all others do in some respects depend.

Gravel, and all the open soils, till the loam is come at, are of the sandy kind.

Those binding earths from the loam downwards, till the stiffness of chalk may be come at, may be reckoned of the clay kind.

All these sorts of earth have a little tendency to vegetation, and have their salts proper for it, but in a different proportion; as a peck of clay may probably have double the quantity of salts in it that a peck of loam has, and a peck of loam may have six times the quantity of salts that a peck of sand has.

Loam. Some call the superficial earth that we meet with in England by this name, without having regard to what proportion of sand and clay it contains: others again call that earth loam, that inclines more to clay than sand. Some by loam mean that sort of earth that equally partakes of sand and clay, being a medium between sand and clay, which they call mother earth; but the true definition of loam is, that sort of earth which is fat and slippery, not of so close a texture as clay, nor too loose and sandy, but of a middle nature between them, and is easily dissolved by frost, and gentle or easy to be wrought. This is one of the best soils for most esculent plants and roots.

This mother earth, they say, may be in colour either black or yellow, and of which of these colours soever it be, plants of most sorts will grow in it.

Sand and clay likewise produce certain plants, which are natural to each of them, and consequently will thrive better in them than in any other soil.

But sand is apt to precipitate those plants that are set in it, earlier than clay, and will cause them to germinate near a month sooner than those that grow in clay, and that for this reason, because the salts which are in sand, are liable to be put in motion by the least approach of the warmth of the sun; but as sand is quick in the operation, the salts are soon exhaled and spent.

Clay. The pores of clay are more closely compacted together, and do not so easily give out those salts that are contained in it; nor can the fibres of every tender plant make their way through it in quest of their proper nutriment.

But if the parts of the clay be opened, by digging and breaking it into small particles, and those parts be kept open by a mixture of some sharp sand, or some other body of the like quality, the effects of its vigour will plainly appear.

Some distinguish the several temperaments of the earth either into a light, sandy, or loose contexture, or into those of a stiff, clayey, or close one, either of which

which have their respective good qualities; and all of them, when they are in their extremes, require art to render them useful and beneficial in the production and growth of plants.

A light, sandy, or loose earth, requires a proper ligature, and should have a compost of a heavier nature; and those that are heavy, clayey, and cloddy, should have a compost of a more fiery sprightly nature, that will insinuate itself into the heavy, lumpy, indigested clods, which would otherwise very much obstruct the business of vegetation.

A good earth should be of a blackish colour, fat, pliant, or easy to be digged; it should be neither cold nor light; it ought to have no ill smell or taste, and it should be of the same quality three or four feet deep for trees, which, if they have not that depth, will languish and decay after they have been planted six years. But this depth is not required for fruit-trees, which will thrive very well if they have two feet and a half of good earth, and generally produce the most generous fruits, when their roots spread near the surface of the earth.

In order to know whether the earth has any ill smell or taste, they direct to lay a handful of it to soak in water for seven or eight hours, and afterwards to strain it, and taste and smell it, by which the taste or smell will easily be perceived.

E A R W I G S.

These are very troublesome vermin in a garden, especially where Carnations are preserved; for they are so fond of these flowers, that if care is not taken to prevent them, they will entirely destroy them, by eating off the sweet part at the bottom of the petals or leaves. To prevent which, most people have stands erected, which have a basin of earth or lead round each supporter, which is constantly kept filled with water. See the article CARNATION.

Others hang the hollow claws of crabs and lobsters upon sticks in divers parts of the garden, into which these vermin get; and by often searching them, you will destroy them without much trouble, which will be of great service to your wall fruit, for these are great destroyers of all soft fruits.

E B E N U S. Lin. Gen. Nov. Barba Jovis. Tourn. Inst. R. H. tab. 419. Ebony.

The CHARACTERS are,

The empalement of the flower is of one leaf, which is divided into five acute segments at the top; the flower is of the butterfly kind; the vexillum is obtuse and reflexed; the wings are equal in length with the vexillum; they are broad and roundish; the keel is shorter and turns upwards. It hath ten stamina, nine joined, standing together, and the other separate, terminated by single summits. In the bottom is situated an oblong germen, supporting a rising style, crowned by a single stigma. The germen afterward becomes an oblong swelling pod, opening with two valves, and inclosing three or four kidney-shaped seeds. This is distinguished from Trifolium, by the bractæ which are situated between the flowers on the spike.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, the flowers having ten stamina in two bodies.

We know but one SPECIES of this genus, viz.

EBENUS. Lin. Sp. Plant. 764. Ebony. Barba Jovis lagopoides, Cretica, frutescens, incana, flore spicato purpureo amplo. Breyn. Prod. 2. *Shrubby Hares-foot Jupiter's Beard of Crete with hoary leaves, and a large purple flower growing in spikes.*

This plant grows naturally in Crete, and in some of the islands of the Archipelago; it rises with a shrubby stalk three or four feet high, which puts out several side branches, garnished with hoary leaves at each joint, which are composed of five narrow spear-shaped lobes, which join at their tails to the foot-stalk, and spread out like the fingers of a hand. The branches are terminated by thick spikes of large purple flowers, which are of the butterfly or Pea-bloom kind; the spikes are from two to three inches long, so that the plant is very bushy, especially when the plants

are strong, and have many spikes of flowers on them. It flowers in June and July, and in very warm seasons will sometimes perfect their seeds in England.

This is propagated by seeds, which should be sown in the autumn, for those which are sown in the spring often fail; they must be sown in pots, and placed under a frame in the winter, where they may be protected from frost. In the spring the plants will come up, which should be kept clean from weeds, and refreshed now and then with water. When these have acquired strength enough to be removed, they should be each planted in a separate small pot filled with light earth, and plunged into a moderate hot-bed just to promote their taking new root; then they should be gradually inured to bear the open air, into which they should be removed the latter end of May, placing them in a sheltered situation, where they may remain till autumn, when they must be removed into shelter; for these plants will not live in the open air through the winter, nor should they be too tenderly treated, lest they draw up weak. I have found them succeed best when placed in an airy glass-case without fire in winter, where they will have more sun and air than in a green-house. During the winter season, the plants must be sparingly watered, but in the summer they will require to be often refreshed. The other management is the same as for other of the hardier exotic plants, among which this will make a fine variety.

E B U L U S. See S A M B U C U S.

ECHINATE SEEDS [of echinus, Lat. a hedge-hog,] such seeds of plants as are prickly and rough.

ECHINOMELOCACTUS. See CACTUS.

ECHINOPHORA. Lin. Gen. Plant. 292. Tourn. Inst. R. H. 656. tab. 423. [of *ἔχινος*, a hedge-hog, and *φέρω*, Gr. to bear.] Prickly Parsnep.

The CHARACTERS are,

It hath an umbellated flower; the general umbel is composed of many smaller, the intermediate being the shortest; the involucre of the general umbel ends in acute thorns; those of the rays are turbinate, of one leaf, cut into six unequal parts, with acute points; the perianthium is divided into five parts, and sits on the germen; the general umbel is uniform; the flowers have five unequal petals which spread open; they have each five stamina, terminated by roundish summits. Under the perianthium is situated an oblong germen within the empalement, supporting two styles, crowned by single stigmas; the germen afterward turns to two seeds, which are inclosed in the hard empalement.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. **ECHINOPHORA** (*Spinosa*) foliolis subulato-spinosis integerrimis. Lin. Sp. Plant. 344. *Prickly-headed Parsnep, with awl-shaped prickly leaves which are entire.* Echinophora maritima spinosa. Tourn. Inst. 656. *Prickly maritime Parsnep.*
2. **ECHINOPHORA** (*Tenuifolia*) foliolis incis inermibus. Lin. Sp. Plant. 344. *Prickly-headed Parsnep, whose small leaves are cut, but have no thorns.* Echinophora pastinacæ folio. Tourn. Inst. 656. *Prickly-headed Parsnep with a Carrot leaf.*

These plants grow naturally on the borders of the Mediterranean sea; they are preserved in the gardens of botany for the sake of variety; they have both perennial roots, which creep in the ground; the first hath branching stalks, growing five or six inches high, which are garnished with short thick leaves, that terminate in two or three sharp thorns; they are placed by pairs opposite: the flowers grow in an umbel, sitting upon a naked foot-stalk, which arises from the side of the stalk; they are white, and under the umbel is situated an involucre, composed of several leaves, which terminate in sharp spines. It flowers in June, but seldom ripens seeds in this country.

The second sort rises near a foot and a half high; from the principal stalk are sent out two side branches

at every joint, which are placed opposite; the lower part is garnished with leaves, which are finely divided like those of the Carrot; the flowers grow in small umbels at the extremity of the branches, having a short prickly involucre. This flowers in July, but doth not ripen seeds in England.

These plants are propagated by their creeping roots in England, as they do not produce seeds here: the best time to transplant them is the beginning of March, a little before they shoot. The roots should be planted in a gravelly or sandy soil, and in a warm situation, or otherwise they should be covered in the winter to prevent the frost from destroying them.

ECHINOPS. Lin. Gen. Plant. 829. Echinopus. Tourn. Inst. R. H. tab. 463. Globe Thistle.

The CHARACTERS are,

It hath a permanent perianthium, which is oblong, angular, and imbricated; the flower hath one funnel-shaped petal, which is divided at the top into five parts, which spread open and are reflexed. It hath five short hairy stamina, terminated by cylindrical summits. In the bottom of the tube is situated an oblong germen, supporting a slender style the length of the tube, crowned by two oblong depressed stigmas which turn back; the germen afterward becomes an oblong oval seed narrowed at the base, but obtuse and hairy at the top.

This genus of plants is ranged in the first section of Linnaeus's seventeenth class, intitled Syngenesia Polygamia Aequalis. This section includes those plants which have only hermaphrodite fruitful florets.

The SPECIES are,

1. **ECHINOPS** (*Spherocephalus*) capitulis globosis pubescentibus. Lin. Sp. Plant. 1314. *Globe Thistle with globular heads and hairy leaves.* Echinopus major. J. B. 3. p. 69. *Greater Globe Thistle.*
2. **ECHINOPS** (*Ritro*) capitulo globofo, foliis supra glabris. Lin. Sp. Plant. 1314. *Globe Thistle with a globular head, and the upper side of the leaves smooth.* Echinopus minor. J. B. 3. 72. *Smaller Globe Thistle.*
3. **ECHINOPS** (*Strigosus*) capitulis fasciculatis calycibus, lateralibus sterilibus, foliis supra strigosis. Lin. Sp. Plant. 1315. *Globe Thistle with bundled heads, whose side empalements are barren, and wing-pointed leaves.* Echinopus minor annuus, magno capite. Tourn. Inst. 463. *Smaller annual Globe Thistle with a large head.*
4. **ECHINOPS** (*Græcus*) caule unicapitato, foliis spinosis, omnibus pinnatifidis villosis, radice reptante. *Globe Thistle with one head on each stalk, prickly leaves, which are all wing-pointed and woolly, and a creeping root.* Echinopus Græcus, tenuissime divisus & lanuginosus, capite minori cæruleo. Tourn. Cor. 34. *Greek Globe Thistle whose leaves are divided into narrow segments and are woolly, with a smaller blue head.*

The first is the common Globe Thistle, which has been long cultivated in some gardens for the sake of variety; this grows naturally in Italy and Spain; it hath a perennial root, from which arise many stalks that grow to the height of four or five feet; these are garnished with long jagged leaves, which are divided into many segments almost to the midrib, the jags ending in spines; they are of a dark green on their upper side, but woolly on their under; the flowers are collected in globular heads, several of these grow upon each stalk; the common hath blue flowers, but there is a variety of it with white. It flowers in July, and the seeds ripen in August.

This plant is easily propagated by seeds, which, if permitted to scatter, the plants will come up in plenty, so a few of them may be transplanted to the places where they are designed to remain to flower; they require no other culture but to keep them clean from weeds: the second year they will flower and produce seeds, and the roots will continue two or three years after; but if the seeds scatter, the plants will become troublesome weeds; to prevent which, the heads should be cut off as soon as the seeds are ripe.

The second sort grows in the south of France and in Italy; this hath a perennial creeping root, which sends up several strong stalks that rise two feet high,

garnished with leaves, which are cut into many fine segments to the midrib, which are set with prickles, and are white on their under side: the stalks branch out toward the top; each of these branches is terminated by a globular head of flowers, which are smaller than those of the first, and of a deeper blue; there is also a variety of this with white flowers. This flowers about the same time as the first, and is propagated in the same way. These will both grow in almost any soil or situation.

The third sort grows naturally in Spain and Portugal: this is an annual plant, which rises with a stiff white stalk two feet high, garnished with divided leaves, ending in many points which have spines; their upper side is green, and covered with brown hairs, their under side white and woolly; the stalk is terminated by one large head of pale blue flowers. These appear in July, and if the season proves warm and dry, the seeds will ripen in autumn, but in wet cold years they rarely ripen here.

These seeds should be sown in the spring, upon a border of light earth, where the plants are to remain; and they require no other management, but to thin them where they are too close.

The fourth sort grows naturally in Greece, from whence Dr. Tournefort sent the seeds to the royal garden at Paris: this hath a perennial creeping root, by which it multiplies fast enough; the stalks rise about a foot high, and are closely garnished with leaves which are shorter and much finer divided than either of the former sorts; these are hoary, and armed on every side with sharp thorns; the stalks are terminated by one middle-sized globular head of flowers, which in some are blue, and in others white. They appear the latter end of June, and in warm seasons the seeds will ripen well in England. This is easily propagated by its creeping roots, or from seeds; it loves a dry soil and a warm situation.

ECHINUS, Lat. is the prickly head or cover of the seed or top of any plant, so called from its likeness to a hedgehog.

ECHIUM. Lin. Gen. Plant. 157. Tourn. Inst. R. H. 135. tab. 54. [Of *Ἐχίς*, Gr. a viper, because the ripe seed of this plant resembles the head of a viper. It is called *Herba Viperaria*, because the ancients believed that this plant killed vipers.] Viper's Bugloss; in French, *Viperine*.

The CHARACTERS are,

The flower hath a permanent empalement, divided into five segments. It hath one petal with a short tube, having an erect broad brim, cut into five parts, and is obtuse; the two upper being longer than the lower, which are acute and reflexed. It hath five awl-shaped stamina, terminated by oblong prostrate summits. In the bottom are situated four germen with one slender style, crowned by an obtuse bifid stigma; the germen afterward become so many roundish pointed seeds, inclosed in the rough empalement.

This genus of plants is ranged in the first section of Linnaeus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. **ECHIUM** (*Anglicum*) caule simplici erecto, foliis lanceolatis, floribus spicatis lateralibus, staminibus corolla æquantibus. *Viper's Bugloss with a single erect stalk, having rough spear-shaped leaves, and flowers in spikes proceeding from the side, with the stamina equalling the petal.* Echium vulgare C. B. P. 254. *Common Viper's Bugloss.*
2. **ECHIUM** (*Vulgare*) caule simplici erecto, foliis caulinis lanceolatis hispidis, floribus spicatis lateralibus staminibus corollâ longioribus. *Viper's Bugloss with a single erect stalk, having rough narrow spear-shaped leaves, flowers growing in short spikes on the sides, and stamina longer than the petal.* Lycopsis Anglica. Lob. *English Lycopsis.*
3. **ECHIUM** (*Italicum*) corollis vix calycem excedentibus, margine villosis. Hort. Upsal. 35. *Viper's Bugloss, whose petals scarce exceed the empalement, having hairy borders.* Echium majus & asperius, flore albo. C. B. P. 255. *Great rough Viper's Bugloss with a white flower.*

4. **ECHIUM**

4. ECHIAM (*Lusitanicum*) corollis stamine longioribus. Lin. Sp. 200. *Viper's Bugloss with the petal of the flower longer than the stamina.* Echium amplissimum folio, Lusitanicum. Tourn. *Portugal Viper's Bugloss with a large leaf.*
5. ECHIAM (*Creticum*) calycibus frutescentibus distantibus, caule procumbente. Lin. Hort. Upsal. 35. *Viper's Bugloss with fruitful empalements growing at a distance, and a trailing stalk.* Echium Creticum latifolium rubrum. C. B. P. 254. *Broad-leaved Viper's Bugloss of Candia, having a red flower.*
6. ECHIAM (*Angustifolium*) caule ramoso, aspero, foliis calloso-verrucosis, staminibus corollâ longioribus. *Viper's Bugloss with a rough branching stalk, warted leaves, and stamina longer than the petal.* Echium Creticum angustifolium rubrum. C. B. P. 254. *Narrow-leaved Viper's Bugloss of Candia, having a red flower.*
7. ECHIAM (*Fruticosum*) caule fruticoso. Hort. Cliff. 43. *Viper's Bugloss with a shrubby stalk.* This is the Echium Africanum fruticans, foliis pilosis. Hort. Amst. 2. p. 107. *Shrubby African Viper's Bugloss, having hairy leaves.*

The first sort grows naturally in Germany and Austria, from whence I received the seeds. This and our common Viper's Bugloss, which is the second, have been confounded by most of the writers on botany, who have supposed they were the same plant, whereas they are very different; for the leaves of this are shorter, and much broader than those of the second; the spikes of flowers are much longer, and the stamina of the flowers are in this equal in length with the petal; whereas those of the second stand out much beyond the petal, which is an essential difference.

The second sort grows naturally upon chalky lands in most parts of England: this is what Lobel titles *Juncopis Anglica*, and has been generally taken for the common Echium.

The third sort grows naturally in the south of France, in Italy, and the isle of Jersey; this rises with an upright hairy stalk; the flowers are produced in short spikes on the side of the branches; they are small, and scarce appear above the empalements; some plants have white flowers, and others are purplish; the empalements of the flowers are very hairy, and cut into acute segments.

The fourth sort grows naturally in Portugal and Spain; the lower leaves of this are more than a foot long, and two inches broad in the middle, gradually lessening to both ends; these are covered with soft hairs. The stalks grow two feet high; the flowers are in short spikes coming from the side of the stalks; the petals of these are longer than the stamina.

The fifth sort grows naturally in Crete; this hath trailing hairy stalks, which grow about a foot long, and put out several side branches, garnished with hairy spear-shaped leaves about three inches long, and three quarters of an inch broad, sitting close to the stalks. The flowers come out on slender spikes upon long foot-stalks, which come from the wings of the leaves; they are large, of a reddish purple colour, which turns to a fine blue when they are dried; these stand at a distance from each other on the spike. It is an annual plant, which flowers in July and decays in autumn.

The sixth sort hath branching stalks which grow a foot and a half long, declining toward the ground; they are covered with stinging hairs; the leaves are four inches long, and not more than half an inch broad; these are pretty much warted, and are hairy. The flowers grow in loose spikes from the side of the stalks, and also at the end of the branches; they are of a reddish purple colour, but not so large as those of the former sort, and the stamina of these are longer than the petal. This is also an annual plant, which grows naturally in Crete.

These are most of them biennial plants, except the fifth and sixth sorts, which are annual, and are the most beautiful of all the kinds: the seeds of these must be sown every year, in the places where they are de-

signed to remain; and the plants require no other culture but to keep them clean from weeds, and thin them where they grow too close. In July they flower; and their seeds ripen in five or six weeks after. The seeds of the other sorts being sown in the spring, will the second summer after produce flowers and seeds, after which they seldom continue. They all delight in a rubbishy gravelly soil, and will grow upon the tops of old walls or buildings; where, when once they have established themselves, they will drop their seeds, and thereby maintain a succession of plants without any care, and on these places they appear very beautiful.

The seventh sort grows naturally at the Cape of Good Hope, from whence the seeds were brought to Holland, where the plants are now preserved in some curious gardens. This rises with a shrubby stalk two or three feet high, dividing upward into several branches, garnished with oval leaves placed alternate, whose base sits close to the stalk; they are hairy, and of a light green colour. The flowers are produced singly between the leaves at the end of the branches; they are of a purple colour, and in shape much like those of the fifth sort. These appear in May and June, but the seeds do not ripen in England.

It is propagated by seeds, when they can be obtained, which should be sown in pots filled with light sandy earth soon after they are received. These may be exposed to the open air till the beginning of October, when the pots should be placed under a frame, to guard them from frost; but in mild weather, they should be opened to have the free air, to prevent the seeds from vegetating till the winter is past; for if the plants come up at that season, their stems will be weak and full of juice, and very liable to rot with damps; therefore it is much better if the plants do not come up till toward March, which is the usual time of their appearing, when the seeds are not forced by warmth. When the plants are fit to remove, they should be each planted into a small pot filled with light earth, and placed under a frame to forward their putting out new roots; then they should be gradually inured to bear the open air, and the latter end of May be placed abroad in a sheltered situation, where they may remain till the beginning of October; at which time they must be removed into an airy glass-case, where they may enjoy the sun and have free air in mild weather. During the winter season these plants must be sparingly watered; for as their stems are succulent, so much moisture will cause them to rot. In the summer they should be set abroad in a sheltered situation, and treated in the same manner as other plants from the same country.

EDERA QUINQUEFOLIA. See VIRIS.

EDGINGS. The best and most durable plant for edgings in a garden is Box; which, if well planted, and rightly managed, will continue in beauty several years: the best season for planting this, is either in the autumn, or very early in the spring; for if you plant it late, and the season should prove hot and dry, it will be very subject to miscarry, unless great care be taken to supply it with water. The best sort for this purpose is the dwarf Dutch Box.

These edgings are only planted upon the sides of borders next walks, and not (as the fashion was some years ago) to plant the edgings of flower-beds, or the edges of fruit-borders in the middle of gardens, unless they have a gravel-walk between them; which renders it proper to preserve the walks clean, by keeping the earth of the borders from washing down into the walks in hard rains.

It was also the practice formerly to plant edgings of divers sorts of aromatic herbs, as Thyme, Savory, Hyssop, Lavender, Rue, &c. But as these very soon grow woody, so that they cannot be kept in due compass, and in hard winters they are often killed in patches, whereby the edgings are rendered incomplete, they are now seldom used for this purpose.

Some people make edgings of Daisies, Thrift, Catchfly, and other flowering plants; but these also re-

E H R

quire to be transplanted every year, in order to have them handsome; for they soon grow out of form, and are subject also to decay in patches; so that there is not any plant which so completely answers the design as Dwarf Box, which must be preferred to all others for this purpose.

EFFLORESCENCE, *Lat.* the blowing out of a flower.

To EGERMINATE, *Lat.* to bud or spring out.

EHRETIA. Trew. tab. 24.

The CHARACTERS are,

It hath a small, permanent, bell-shaped empalement of one leaf, cut into five points; the flower hath one petal, whose tube is longer than the empalement, cut into five segments; it hath five awl-shaped spreading stamina the length of the corolla, terminated by roundish incumbent summits, and a roundish germen, supporting a slender style the length of the stamina, crowned by an obtuse indented stigma; the germen afterward becomes a round berry with one cell, inclosing four angular seeds.

This genus of plants is ranged in the first order of Linnæus's fifth class; intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. EHRETIA (*Timifolia*) foliis oblongo-ovatis integerrimis glabris, floribus paniculatis. Amœn. Acad. 5. p. 395. *Ehretia with oblong, oval, entire, smooth leaves, and flowers growing in panicles.*

2. EHRETIA (*Bourreria*) foliis ovatis integerrimis lævibus, floribus subcorymbosis, calycibus glabris. Lin. Sp. 275. *Ehretia with oval entire leaves, flowers growing in a sort of corymbus, and smooth empalements. Bourreria fructibus succulentis. Jacq. Amer.*

The seeds of the first sort were sent me from Jamaica in the year 1734, which succeeded in the Chelsea garden, where the plants have grown to the height of eight or nine feet, with strong woody stems, and have several times produced their flowers, but have not perfected their seeds as yet in England. This is by Dr. Linnæus supposed to be the same plant mentioned by Sir Hans Sloane, under the title of *Ceraso affinis arbor baccifera racemosa, flore albo pentapetalo, fructu flavo monopyreno eduli dulces*. Hist. Jam. 2. p. 94. But I differ in my opinion from him, for the leaves of our plant are smoother, longer, and more pointed, and the corymbus of flowers is much longer than in Sir Hans's plant.

This hath a rough woody stalk, which divides into several irregular branches, garnished with oblong, oval, smooth leaves, nine inches long, three broad in the middle, ending in acute points; the flowers are white, and produced in an oblong corymbus toward the end of the branches; they have one petal in each, which is cut at the top into five segments which are reflexed. These appear toward the end of July, but fall away without being succeeded by seeds.

The seeds of the second sort I received from Surinam, which succeeded in the Chelsea garden. This hath a woody upright stem, covered with a brown bark, sending out branches regularly toward the top, garnished with smooth oval leaves placed alternate, having short foot-stalks; the leaves are six inches long, and more than two broad, ending with blunt oval points. As this sort hath not produced flowers here, so I can give no farther account of them. This Doctor Linnæus supposes to be the same with a plant figured by Mr. Catesby, under the title of *Pittonia similis laureolæ foliis, floribus albis, baccis rubris*. But in this he is also mistaken, for there are plants in the Chelsea garden, which were raised from seeds sent from the Bahama Islands, which are very different from the former.

These plants are too tender to thrive abroad in England, where they require a moderate warm stove in winter; but when the plants have acquired strength, they may be placed in the open air during the heat of summer; but it should be in a sheltered situation, and when the evenings grow cold in the autumn, they must be removed into shelter.

They are both propagated by seeds when they can

E L Æ

be obtained, which should be sown in small pots plunged into a hot-bed; they may also be propagated by laying down their branches, but these are long before they put out roots.

ELÆAGNUS. Lin. Gen. Plant. 148. Tourn. Cor. 53. tab. 489. [from *Ἐλαία*, an Olive, and *ἄγνος*; Vitex; because this plant hath leaves like those of the Chastetree, and a fruit like an Olive.] Oleaster, or wild Olive.

The CHARACTERS are,

The flower hath a bell-shaped empalement of one leaf, which is quadrifid, rough on the outside, but coloured within. It hath no petals, but four short stamina which are inserted in the divisions of the empalement, and are terminated by oblong prostrate summits. At the bottom is situated a roundish germen supporting a single style, crowned by a single stigma; the germen afterward becomes an obtuse oval fruit, with a puncture at the top, inclosing one obtuse nut.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, from the flower having four stamina and one style.

The SPECIES are,

1. ELÆAGNUS (*Spinosus*) aculeatus, foliis lanceolatis. *Prickly wild Olive with spear-shaped leaves. Elæagnus Orientalis latifolius, fructumaximo. Tourn. Cor. App. 52. Eastern broad-leaved wild Olive with a large fruit.*

2. ELÆAGNUS (*Inermis*) inermis, foliis lineari-lanceolatis. *Wild Olive without thorns, and narrow spear-shaped leaves. Elæagnus Orientalis angustifolius, fructu parvo olivæformi subdulci. Tourn. Cor. App. 52. Eastern wild Olive with narrow leaves, and a small, sweet, Olive-shaped fruit.*

3. ELÆAGNUS (*Latifolia*) foliis ovatis. Prod. Leyd. 250. *Wild Olive with oval leaves. Elæagnus foliis rotundis maculatis. Burm. Pl. Zeyl. 92. Wild Olive with round spotted leaves.*

The first and second sorts Dr. Tournefort found growing naturally in the Levant, and the first I take to be the common sort, which grows naturally in Bohemia, of which I saw some trees growing in the curious garden of the late Dr. Boerhaave, near Leyden, in Holland. The leaves of this sort are not more than two inches long, and about three quarters of an inch broad in the middle; they are white, and have a soft cottony down on their surface; at the foot-stalk of every leaf, there comes out a pretty long sharp thorn; as the leaves are placed alternate on the branches, so the spines come out on each side the branches; just below the foot-stalks of the leaves, they are alternately longer: the flowers are small, the inside of the empalement is yellow, and they have a strong scent when fully open.

The second sort hath no thorns on the branches, the leaves are more than four inches long, and not half an inch broad; they are very soft, and have a shining appearance like satin. The flowers come out at the foot-stalks of the leaves, sometimes singly, at other times two, and frequently three at the same place; the outside of the empalement is silvery and studded, the inside of a pale yellow, having a very strong scent. This flowers in July, and sometimes the flowers are succeeded by fruit. This is the sort which is most commonly preserved in the English gardens.

These plants may be propagated by laying down the young shoots in autumn, which will take root in one year, when they may be cut off from the old trees, and either transplanted into a nursery for two or three years to be trained up, or into the places where they are to remain. The best season for transplanting of these trees is in the latter end of February, or the beginning of March; though they may be removed at Michaelmas, provided the roots are mulched, to protect them from severe frost in winter. These plants should be placed where they may be screened from strong winds, for they grow very freely, and are very subject to be split down by the wind, if they are too much exposed.

These

E L E

These trees commonly grow to twelve or fourteen feet high, and when they are intermixed with other trees of the same growth, make a pretty diversity; for their leaves being of a silver colour, are easily distinguished at a distance.

The third sort grows naturally at Ceylon, and in some other parts of India. This is pretty rare at present in the English gardens, but some years past there were several pretty large plants of it growing in the garden at Hampton Court. This rises with a woody stem to the height of eight or nine feet, dividing into many branches, garnished with oval silvery leaves, which have several irregular spots of a dark colour on their surface; they are placed alternately on the branches, and continue all the year. The flowers I have not seen; though some of the trees at Hampton Court produced flowers, but I was not so lucky as to see them.

This sort requires a warm stove to preserve it in this country, for it is too tender to live in the open air, excepting for a short time in the warmest part of summer.

The two first sorts are extremely hardy, so are not injured by the frost, but the trees are not of very long duration, therefore young plants should be raised once in three or four years, to preserve the kinds.

ELATERIUM. See MOMORDICA.

ELATINE. See LINARIA.

ELECAMPANE. See INULA.

ELEPHANTOPUS. Lin. Gen. Plant. 827. Vaill.

Aët. Par. 1719. Dill. Hort. Elth. 104. [of *Ἐλεφας*, an elephant, and *Πῆς*, a foot,] Elephant's foot; so called by Monsieur Vaillant, because he says the under leaves of the first sort somewhat resemble an Elephant's foot.

The CHARACTERS are,

There are many flowers collected together in one common large involucre which is permanent, and each empalement contains four or five florets; the florets are tubulous and hermaphrodite; they have one petal which is tongue-shaped; the brim is narrow, and divided into five equal parts; they have five very short hairy stamens, terminated by cylindrical summits. In the bottom is situated an oval germen, supporting a slender style, crowned by two slender stigmas; the germen afterward becomes a single compressed seed crowned with bristles, sitting on a placenta inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's seventeenth class, which includes the plants with flosculous flowers, whose florets are all hermaphrodite and fruitful.

The SPECIES are,

1. ELEPHANTOPUS (*Scaber*) foliis oblongis scabris. Hort. Cliff. 390. *Elephantopus with oblong rough leaves.* Elephantopus conyzæ folio. Vaill. Mem. Acad. Scien. 1719. *Elephant's foot with a Flea-bane leaf.*
2. ELEPHANTOPUS (*Tomentosus*) foliis ovatis tomentosis. Gron. Virg. 90. *Elephantopus with oval woolly leaves.* Elephantopus helenii folio, purpurascens flore. Houst. MSS. *Elephantopus with an Elecampane leaf, and a purplish flower.*

The first sort grows naturally in both the Indies, I have received it from several parts of America; this sends out many oblong rough leaves, which spread near the ground; between these in the spring arises a branching stalk, little more than a foot high. The side branches are short, and are generally terminated by two heads of flowers, each standing upon a short foot-stalk. The heads contain several hermaphrodite florets, included in a common involucre, composed of four oval leaves, ending in acute points. The florets are of a pale purple colour. They appear in July, but are rarely succeeded by seeds in England.

The second sort grows naturally in South Carolina; the plants of this have frequently come up in the earth, which has been sent over from thence with other plants as weeds; this hath several oval woolly leaves, four inches long, and three inches broad, growing from the root, having many transverse nerves, running from the midrib to the sides; they

E L L

spread flat on the ground, and between these arise a stiff stalk, about a foot high, which divides into several branches, each being terminated by two flowers, which are composed of several florets, inclosed in a four-leaved involucre; two of these leaves are alternately larger than the other. The involucre is longer than the florets, so they do but just appear within the two larger leaves; the flowers make no appearance. They appear in July, but the seeds never ripen in this country.

The first sort hath a perennial root, but an annual stalk. If this is planted in pots, and sheltered in the winter from frost, it may be preserved several years, and the plants will annually flower; but the second sort seldom continues longer than two years.

These plants are propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are come up, they must be transplanted into pots filled with fresh light earth, and plunged into a hot-bed of tanners bark, observing to water and shade them until they have taken root; then you should let them have a large share of fresh air in warm weather, and they will require to be frequently refreshed with water.

ELEPHAS. See RHINANTHUS.

ELICHRYSUM. See GNAPHALIUM.

ELM. See ULMUS.

ELLISIA.

The CHARACTERS are,

The flower has a permanent empalement, composed of five small, erect, spreading leaves; it is of one petal, funnel-shaped the length of the cup, cut into five obtuse segments at top; it hath five stamens the length of the tube, terminated by roundish summits, and a round germen supporting a short slender style, crowned by an oblong bifid stigma; the germen afterward becomes a roundish fleshy berry with two cells, inclosing two rough seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamens and one style.

We know but one SPECIES of this genus, viz.

ELLISIA (*Nyctelea*) Lin. Sp. 1662. *Tea-leaved Ellisia*

This plant grows naturally in Jamaica, where it forms a bushy shrub about six or seven feet high. I have raised many of the plants from seeds, some of which are now four or five feet high, but have not as yet produced flowers. It sends out many branches from the stem, so as to form a thick bush; the branches are generally covered with a dark purple bark; the leaves also when the plants are exposed in summer turn of the same colour, but after they have been some time removed into the stove, they recover their verdure again. The leaves are placed opposite on the branches, which are an inch and a half long, spear-shaped and indented on their edges, and have commonly two or three small leaves sitting close to the branches; at the foot-stalks of the larger leaves, and at the same place, arises pretty long black spines, generally placed opposite toward the lower part of the branches, but upward they are alternate, and the ends of the branches are without thorns. As the plants have not as yet produced flowers in England, so I can give no farther account of them.

This plant may be propagated by cuttings, which if planted in small pots filled with light earth, and plunged into a moderate hot-bed, covering them close with a hand-glass any time in July, will put out roots in about two months, so may then be separated and put into small pots, plunging them again into the hot-bed to promote their taking new root, after which they should be gradually inured to the open air; but the beginning of October they should be removed into the dry stove, where, during the winter, they should have a moderate warm air, in which they will thrive better than in a great heat.

When seeds of this plant can be procured from abroad, if they are sown on a hot-bed the plants will rise easily, and may be afterward treated in the same way as is directed for those raised by cuttings.

EMERUS.

E M E

EMERUS. Tourn. Inst. R. H. 650. Coronilla. Lin. Gen. Plant. 789. [this name was given it by Theophrastus, and restored by Cæsalpinus.] Scorpion Sena.

The CHARACTERS are,

The flower hath a very short empalement of one leaf, divided into five parts which is permanent. The flower is of the butterfly kind. The tails of the petals are much longer than the empalement. The standard is narrow, and shorter than the wings, over which it is arched. The wings are large and concave. The keel is heart-shaped and reflexed. There are ten stamina in each, one of which stands separate, the other nine are joined; these are situated in the standard. In the empalement is situated an oblong slender germen, supporting a slender style, crowned by a taper stigma. The germen afterward becomes a taper cylindrical pod, swelling in those parts where the seeds are lodged, which are also cylindrical.

This genus of plants is ranged in the third section of Tournefort's twenty-second class, which includes the trees and shrubs with a butterfly flower, whose leaves are placed by pairs along the midrib. Dr. Linnæus has joined this genus, and also the Securidacca of Tournefort to the Coronilla; but hereby the number of species are increased, and therefore it is much better to keep them separate, as there are more essential differences between them, than in some of the other genera of this class which he has separated.

The SPECIES are,

1. **EMERUS** (*Major*) caule fruticoso, pedunculis longioribus caule angulato. *Scorpion Sena with a shrubby stalk, longer foot stalks to the flowers, and angular stalks.* Emerus. Cæsalp. Scorpion Sena, vulgò.
2. **EMERUS** (*Minor*) foliolis obcordatis, pedunculis brevioribus, caule fruticoso. *Scorpion Sena with long heart-shaped leaves, shorter foot-stalks to the flowers, and a shrubby stalk.* Emerus minor. Tourn. Inst. R. H. 650. *Lesser Scorpion Sena.*
3. **EMERUS** (*Herbacea*) caule erecto, herbaceo, foliolis multijugatis, floribus singularibus alaribus, siliquis longissimis erectis. *Scorpion Sena with an erect herbaceous stalk, the leaves composed of many pair of lobes, single flowers proceeding from the sides of the stalks, and very long erect pods.* Emerus siliquis longissimis & angustissimis. Plum. Cat. 19. *Emerus with very long and narrow pods.*

The first of these shrubs is very common in all the nurseries near London; this rises with weak shrubby stalks to the height of eight or nine feet, dividing into many slender branches, garnished with winged leaves, composed of three pair of lobes (or small leaves) terminated by an odd one. The flowers come out upon long foot-stalks from the side of the branches, two or three of these foot-stalks arising from the same point; each of these sustains two, three, or four yellow butterfly flowers; these appear in May, and are frequently succeeded by long slender pods, which are taper, swelling in those parts where the seeds are lodged, and hang downward; these shrubs continue long in flower, especially in cool seasons, and frequently flower again in autumn, which renders them valuable.

The second sort rises with many shrubby stalks like the first, but not more than half the height; this hath larger leaves, which are of an oblong heart-shape. The flowers are rather larger than those of the first, and stand upon shorter foot-stalks; these differences hold in the plants which are raised from seeds, therefore I think they may be allowed to stand as distinct species, though there is a great likeness at first-sight in them.

The leaves of these shrubs, when fermented in a vat, in the same manner as is practised with the Indigo plants, will afford a dye, very near to that of Indigo; but whether it will answer the same purposes is not yet certain, or whether it may be worth cultivating for that purpose, either here or abroad, is what we cannot yet determine; but there is so great affinity between these plants, and those of the Indigo in their generical characters, that Dr. Tournefort, and se-

E M P

veral other botanists, have ranged them in the same genus.

These shrubs are easily propagated by sowing their seeds (which they commonly produce in great plenty) in March, upon a bed of light sandy earth, observing to keep the bed clear from weeds; and in very dry weather the bed must often be refreshed with water, which should be given carefully, lest the seeds should be washed out of the ground by hasty watering. When the plants are come up, they must be kept clean from weeds, and in very dry weather, if they are watered, it will promote their growth; the Michaelmas following (if the plants have thriven well) you may draw out the largest, which may be transplanted into a nursery, at three feet distance row from row, and one foot asunder in the rows. This will give room to those plants which are left to grow in the seed-bed, in which place they may remain another year, when they will also be fit to transplant into a nursery, where they should be two years, when they will be fit to plant out, where they are to remain for good; in doing of which, you should be careful in taking them up, not to break or wound the roots, nor should they remain too long in the nursery before they are transplanted, for they are subject to shoot downright roots, which, when cut off, oftentimes proves the death of the tree. In all other respects it must be treated like other flowering shrubs, among which this is commonly sold at the nurseries. It may also be propagated by laying down the tender branches, which will take root in about a year's time, and may then be transplanted into a nursery, and managed in the same manner as the seedling plants.

The third sort grows naturally in the West-Indies, where Plumier first discovered it in the French settlements; but it was found growing in plenty at La Vera Cruz, in New Spain, by the late Dr. Houkoun, who sent me the seeds, which succeeded in the Chelsea garden, where the plants flowered, but did not perfect their seeds, and the plants being annual, the species was lost here. This rises with a round herbaceous stalk three feet high, which is garnished at each joint with one long winged leaf, composed of about twenty pair of lobes, terminated by an odd one; these have obtuse points, and are of a deep green. The flowers come out singly from the side of the stalk, immediately above the foot-stalk of the leaves, standing upon slender foot-stalks two inches long; they are larger than those of either of the former sorts, and are of a pale yellow colour; these are succeeded by slender con pressed pods, which are more than six inches long, having a border on each side, and a swelling where each seed is lodged.

This is an annual plant, whose seeds must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a separate small pot filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, shading them from the sun until they have taken new root, then they must be treated in the same manner as other exotic plants from those warm countries. If these plants are brought forward in the spring, and kept under a deep frame in a tan-bed, or plunged into the bark-bed, in the stove, when they are grown too tall to remain under common frames, they will ripen seeds in England; for those seeds which I received did not arrive here till May, and yet those plants flowered well in August; but the autumn coming on soon after, prevented their perfecting seeds, and that part of the seed which I reserved till the next year did not grow.

EMPETRUM. Lin. Gen. Plant. 977. Tourn. Inst. R. H. 579. tab. 421. [*Εμπέτρων*, of *εἶν*, in, and *πέτρα*, Gr. a rock or stone, because this tree grows in stony places.] Black-berried Heath.

The CHARACTERS are,

It hath male and female flowers on different plants; the male flowers have a three-pointed empalement, which is permanent; they have three oblong petals, which are narrow at their base, and three long hanging stamina which are

E P H

are hairy, terminated by short two-pointed summits, which stand erect. The female flowers have the same empalement and petals as the male, but no stamina. In the center is situated a depressed germen, supporting nine reflexed spreading stigma. The germen afterward becomes a depressed round berry of one cell, inclosing nine seeds placed circularly.

This genus of plants is ranged in the third section of Linnæus's twenty-second class, which includes those plants whose male and female flowers grow on separate plants, and the male flowers have three stamina.

We have but one SPECIES of this genus in England, viz.

EMPETRUM (*Nigrum*) procumbens. Hort. Cliff. 470. *Trailing Berry-bearing Heath*. Empetrum montanum, fructu nigro. Tourn. Inst. 579. *Black-berried Heath, Crow berries, Crake berries.*

This little shrub grows wild upon the mountains of Staffordshire, Derbyshire, and Yorkshire, and is seldom propagated in gardens unless for variety sake; but it may be cultivated in shady places, and will thrive very well in gardens, where the soil is stiff. The plants should be procured from the places where they grow naturally, for the seeds remain a year in the ground before they vegetate, and afterward are very slow in their growth, so they are not worth the trouble of cultivating from seeds. If the plants are planted on a moist boggy soil in autumn, they will get roots in the winter, and will require no farther care than to clear them from weeds, provided they have a moist soil, otherwise they will require to be frequently watered; for these low shrubs commonly grow upon the tops of wild mountains, where the soil is generally peaty, and full of bogs. The heath cocks feed much upon the berries of this plant; so that wherever there is plenty of these low shrubs, there are commonly many of these fowls to be found.

EMUSCATION, the clearing a tree of moss, *Lat.*

ENUCLEATION, a taking out the nut or kernel of any fruit, *Lat.*

ENULA CAMPANA. See **INULA**.

EPHEDRA. Lin. Gen. Plant. 1007. Tourn. Inst. 663. tab. 477. *Shrubby Horse-Tail*, vulgò.

The CHARACTERS are,

It hath male and female flowers in different plants; the male flowers are collected in katkins, which are scaly; under each scale is a single flower; these have no petals, but seven stamina, which are joined in form of a column, and are terminated by roundish summits. The female flowers have an oval perianthium, composed of five series of leaves, which alternately lie over the divisions of the lower range; these have no petals, but have two oval germen sitting upon the perianthium, supporting short styles, crowned by single stigma. The germen afterward turn to oval berries, each having two seeds.

This genus of plants is ranged in the twelfth section of Linnæus's twenty-second class, intitled Diœcia Monadelphia, the plants of this class and section having male flowers on different plants from the female, and their stamina join in form of a column.

We have but one SPECIES of this genus in England, viz.

EPHEDRA (*Distachia*) pedunculis oppositis, amentis geminis. Hort. Cliff. 465. *Shrubby Horse-Tail with opposite foot-stalks, and twin katkins*. Ephedra maritima minor. Tourn. *Lesser Sea Horse-Tail*.

This is a low shrubby plant, which grows naturally upon the rocks by the sea in the south of France, in Spain, and Italy; it is also preserved in several gardens for the sake of variety, but has little beauty. This hath a low shrubby stalk, which puts out a few short branches, rising about two feet high, which have many protuberant joints, at which come out several narrow rushy leaves, like those of the Horse-Tail, which continue green all the year, but the plants rarely flower in this country.

It may be propagated by offsets, which the plants send forth in great plenty; for the roots creep under ground, and send forth suckers, which may be taken

E P I

off to transplant in the spring. They love a pretty moist strong soil, and will endure the cold of our ordinary winters very well in the open air. Some of these plants were formerly preserved in pots, and were housed in winter, but by later experience they are found to thrive better in the full ground.

EPHEMERUM. See **TRADESCANTIA**.

EPIDENDRUM. Lin. Gen. 1016. *Vanilla*.

There are near thirty species of this genus, which grow naturally upon trees in Africa and both Indies; but as the plants cannot, by any art yet known, be cultivated in the ground, it would be to little purpose the enumerating of them here; though could the plants be brought to thrive by culture, many of them produce very fine flowers of uncommon forms. I had three species of them sent me from America, which were stripped from the trees on which they grew; these I planted with care in pots, which were placed in a stove, where they came so far as to shew their flowers, but the plants soon after perished.

EPIGÆA. Lin. Gen. Plant. 486. *Menecylum*. Mitch. 13. *Trailing Arbutus*.

The CHARACTERS are,

The flower hath a double empalement, which is permanent; the outer is composed of three, and the inner of one leaf, divided at the top into five parts. The flower is of the salver shape, with one petal, having a cylindrical tube, which is longer than the empalement, and hairy within. The brim is cut into five parts, which spread open. It hath ten slender stamina the length of the tube, which are fixed to the base of the petal, and are terminated by oblong summits. In the center is situated a globular hairy germen, crowned by an obtuse quinquedid stigma. The germen afterward becomes a depressed, half globular, five-cornered fruit, having five cells, opening with five valves, containing several seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flowers having ten stamina and one style.

We know but one SPECIES of this genus, viz.

EPIGÆA. Lin. Gen. Plant. 486. *Trailing Arbutus*.

This plant grows naturally in North America, from whence it has been introduced to the English gardens. It is a low plant, with a trailing shrubby stalk, which puts out roots at the joints, and when in a proper soil and situation, multiplies very fast. The stalks are garnished with oblong rough leaves which are waved on their edges. The flowers are produced at the end of these branches in loose bunches; these are white, and divided at the top into five acute segments, which spread open in form of a star. It flowers in July, but doth not produce fruit in England.

The plants are easily propagated by their trailing stalks, which put out roots at the joints, so may be cut off from the old plant, and placed in a shady situation and a moist soil: the best time for this is in autumn, that the plants may be well rooted before the spring. If the winter should prove very severe, it will be proper to lay a few dried leaves, or some such light covering over them, which will prevent their being injured by frost; and after they are well rooted, they will require no farther care but to keep them clean from weeds.

EPILOBIUM. Lin. Gen. Plant. 426. *Chamaenerion*. Tourn. R. H. 302. tab. 157. *Willow Herb*, or *French Willow*.

The CHARACTERS are,

The empalement of the flower is composed of four oblong pointed leaves, which are coloured. The flower hath four bordered petals which spread open, and eight stamina which are alternately shorter, terminated by oval compressed summits. Below the flower is situated a long cylindrical germen, supporting a slender style, crowned by an obtuse quadrifid stigma. The germen afterward becomes a long, cylindrical, furrowed capsule with five cells, filled with oblong seeds, crowned with down.

This genus of plants is ranged in the first section of Linnæus's eighth class, intitled Octandria Monogynia, the flower having eight stamina and one style.

E P I

The SPECIES are,

1. **EPILOBIUM** (*Angustifolium*) foliis sparsis lineari-lanceolatis, floribus inæqualibus. Lin. Sp. 493. *Epilobium with linear spear-shaped leaves which are placed thinly, and unequal flowers.* Chamænerion latifolium vulgare. Tourn. Inst. R. H. 302. *Common broad-leaved Willow Herb, or French Willow.*
2. **EPILOBIUM** (*Hirsutum*) foliis oppositis lanceolatis serratis decurrenti-amplexicaulibus. Lin. Hort. Cliff. 145. *Epilobium with opposite spear-shaped leaves, which are sawed on their edges.* Chamænerion villosum, magno flore purpureo. Tourn. Inst. R. H. 303. *Hoary Willow Herb with a large flower, commonly called Codlins and Cream.*

There are several other species of this genus, some of which grow naturally in shady woods and moist places in most parts of England, where they are often very troublesome weeds, therefore are seldom admitted into gardens, so I shall not trouble the reader with their distinctions.

The first sort here mentioned was formerly planted in gardens for the beauty of its flowers; but as it usually spreads far by the creeping roots, whereby it over-runs all the neighbouring plants, it has been generally cast out of most gardens: however, in some low moist places, or in great shade, if there was a place assigned for this plant, it will make a good appearance when it is in flower, and these flowers are very proper to cut for basons to adorn chimnies in the summer season. This usually grows about four feet high, with slender stiff branches, which are beset with leaves, resembling those of the Willow, from whence it had the name of Willow Herb, or French Willow. On the upper part of the stalks the flowers are produced in a long spike or thyse, which are of a fine Peach colour, and, if the season is not very hot, they will continue near a month in beauty. This sort is found growing wild in divers parts of England, but several botanists have supposed it was only found in such places where the plants had been cast out of gardens; however, I think it must be allowed to be a native of this country, since it is found in great plenty in woods at a great distance from any habitation, particularly in Charlton forest, and several other woods in Suffex. It is a great creeper at the root, so may be easily propagated.

There is a variety of this with white flowers, which is planted in gardens, but differs from it only in the colour of the flower; however, some persons are fond of propagating these varieties, for which reason I mentioned it here.

The second sort is found wild by the side of ditches and rivers in many parts of England. This plant grows about three feet high, and produces its flowers on the top of the stalks; but these are much less beautiful than those of the first, and the plant being a great Rambler at the root, is seldom admitted into gardens. The leaves of this plant being rubbed, emit a scent like scalded Apples, from whence some have given the name of Codlins and Cream to this plant.

EPIEDIUM. Lin. Sp. Plant. 138. Tourn. Inst. R. H. 232. tab. 117. Raii Meth. Plant. 129. Barrenwort.

The CHARACTERS are,

The flower hath a three-leaved empalement which falls off. It hath four obtuse oval fruit, which are concave, and spread open, and four nectariums which are cup-shaped, obtuse at the bottom, and as large as the petals. It hath four stamina, terminated by oblong, erect, bilocular summits. The oblong germen is situated at the bottom, supporting a short style, crowned by a single stigma. The germen afterward becomes an oblong pointed pod, with one cell, opening with two valves, inclosing many oblong seeds.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

We know but one SPECIES of this genus, viz.

1. **EPIEDIUM** (*Alpinum*.) Hort. Cliff. 37. *Alpine Barrenwort.*

E R I

This plant hath a creeping root, from which arise many stalks about nine inches high, divided at the top into three, each of which is again divided into three smaller; upon each of these stands a stiff heart-shaped leaf, ending in a point, of a pale green on the upper side, but gray on the under. A little below the first division of the stalk comes out the foot-stalk of the flowers, which is near six inches long, dividing into smaller, each of these sustaining three flowers; these are composed of four leaves, placed in form of a cross; they are of a reddish colour, with yellow stripes on the border. In the center of the flower arises the style, situated upon the germen, which afterward turns to a slender pod, containing many oblong seeds. It flowers in May, and the leaves decay in autumn. The roots, if planted in a shady border, should be every year reduced, so as to keep them within bounds; otherwise it will spread its roots and interfere with the neighbouring plants. It grows naturally on the Alps, but I received some plants of it which were found growing naturally in a wood in the North of England.

EPIPHYLLOSPERMOUS PLANTS [of ἐπι, upon, φύλλον, a leaf, and σπέρμα, Gr. seed,] such plants as bear their seeds on the back of their leaves, the same as capillaries.

EQUINOCTIAL, ÆQUINOCTIAL [of equus, equal, and nox, Lat. night.] A great and immoveable circle of the sphere, under which the equator moves in its diurnal motion.

The equinoctial, or equinoctial line, is ordinarily confounded with the equator; but there is a difference, the equator being moveable, and the equinoctial unmoveable, and the equator drawn about the convex surface of the sphere, but the equinoctial on the concave surface of the Magnus Orbis.

The equinoctial is conceived, by supposing a semi-diameter of the sphere, produced through a point of the equator, and there describing a circle on the immoveable surface of the Primum Mobile, by the rotation of the sphere about its axis.

Whenever the sun comes to this circle, in his progress through the ecliptic, it makes equal day and night all round the globe; as then arising due east, and setting due west, which he never does at any other times of the year.

The people who live under this circle, have their days and nights constantly equal; and the sun is in their zenith at noon, and casts no shadow.

EQUINOXES are the times when the sun enters into the equinoctial points, which are the two points where the equator and ecliptic intersect each other; the one being in the first point of Aries, called the vernal equinox; and the other in the first point of Libra, called the autumnal equinox.

So the equinoxes happen when the sun is in the equinoctial circle, when, of consequence, the days are equal to the nights throughout the world, which is the case twice a year, viz. about the 21st of March, and the 22d of September; the first of which is the vernal, and the second the autumnal equinox.

EQUISETUM [of equus, a horse, and seta, a bristle, because the leaves and branches represent the bristles or hair of a horse's main or tail. It is by the Greeks called ἵππουρις, of ἵππος, a horse, and οὐρά, a tail; and hippoſeta, of ἵππος and seta.] Horse-Tail.

There are several species of this plant, which are found in England, on the sides of ditches, or in shady woods; but as they are plants which are never cultivated in gardens, I shall pass them over in this place.

ERANTHEMUM. See ADONIS.

ERICA. Lin. Gen. Plant. 435. Tourn. Inst. R. H. 602. tab. 373. [Ἐρίκη, of ἐρίκω, or ἐρίκω, Gr. to break, because this plant is said to have the virtue of breaking the stone in the bladder.] Heath; in French, *Bruyere*.

The CHARACTERS are,

The flower hath a coloured permanent empalement of four oval

oval erect leaves. It hath one swelling petal, which is erect and quadrifid, and eight hairy stamina, which are fixed to the receptacle, and terminated by bifid summits. In the bottom is situated the roundish germen, supporting a declining style, which is longer than the stamina, crowned by a four-cornered stigma. The germen afterward becomes a round capsule, having four cells, which are filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's eighth class, intitled Octandria Monogynia, the flower having eight stamina and one style.

The SPECIES are,

1. ERICA (*Vulgaris*) antheris bicornibus inclusis, corollis inæqualibus, campanulatis mediocribus foliis oppositis sagittatis. Lin. Sp. Plant. 352. Heath with two horns including the summits, bell-shaped unequal petals, and middling arrow-pointed leaves placed opposite. Erica vulgaris glabra. C. B. 485. Common smooth Heath.
2. ERICA (*Herbacea*) antheris bicornibus inclusis campanulatis mediocribus secundis, foliis ternis triquetris parulis. Lin. Sp. Plant. 500. Heath with a horned summit, a bell-shaped petal, and five narrow spreading leaves. Erica foliis coridis, multiflora. J. B. vol. 1. p. 356. Pine-leaved Heath with many flowers.
3. ERICA (*Cinerea*) antheris bicornibus inclusis, corollis ovatis racemosis, foliis ternis glabris linearibus. Lin. Sp. Plant. 352. Heath with two horns including the summits, oval branchy petals, and three long, narrow, smooth leaves. Erica humilis, cortice cinereo, arbuti flore. C. B. P. 486. Dwarf Heath with an Ash-coloured bark, and Strawberry-tree flower.
4. ERICA (*Ciliaria*) antheris simplicibus inclusis, corollis ovatis irregularibus, floribus ternoracemosis, foliis ternis ciliatis. Læff. Epist. 2. p. 9. Lin. Sp. Plant. 354. Heath with single summits, oval irregular petals, triple branching flowers, and hairy leaves placed by threes.
5. ERICA (*Arborea*) antheris bicornibus inclusis, corollis campanulatis longioribus, foliis quaternis patentissimis, caule subarboreo tomentoso. Lin. Sp. 502. Tree Heath, whose antheræ are included in two horns, a longer bell-shaped flower, and four spreading leaves at each joint.

The four first sorts grow wild upon barren uncultivated places in divers parts of England; but notwithstanding their commonness, yet they deserve a place in small quarters of humble flowering shrubs, where, by the beauty and long continuance of their flowers, together with the diversity of their leaves, they make an agreeable variety.

These are seldom propagated in gardens, and so not to be had from the nurseries, but may be taken up, with a ball of earth to their roots, from the natural place of their growth in autumn, and may be transplanted into the garden. The soil where they are planted should not be dunged, nor should you bestow any other culture on them than clearing them from weeds; for the less the ground is dug, the better these will thrive, for they commonly shoot their roots near the surface, which, in digging, are subject to be hurt, whereby the plant is often destroyed; these may also be propagated by seeds, but this being a tedious method, the other is much preferable to it.

The fifth sort grows naturally at the Cape of Good Hope, and also in great plenty in Portugal, where it rises with a strong ligneous stem to the height of eight or ten feet, sending out many branches the whole length, garnished with narrow leaves, four coming out from the same point; the flowers are produced between the leaves on the upper part of the branches; they are white, with a blush of red on their outside; these appear in May, but are not succeeded by seeds in England.

This plant will live in the open air in England, provided it is planted in a dry soil and a warm situation, but is generally kept in pots and housed in winter; however, the plants so managed, do not thrive or flower so well as those in the full ground, therefore it is much better to be at the trouble of sheltering the plants in the ground in winter, than to keep them in pots.

It is with difficulty propagated here, which is done by laying down the young shoots, though these are often two years before they put out roots: others plant the young slips or cuttings into pots filled with light earth, covering them close with a bell-glass, and shading them from the sun; where this is skilfully practised, the cuttings will put out roots, and make better plants than the layers.

ERICA BACCIFERA. See EMPETRUM.

ERIGERON. Lin. Gen. Plant. 855. Senecionis. Sp. Dill. Conyzella. Dill. Groundsel.

The CHARACTERS are,

It hath a compound radiated flower, composed of many hermaphrodite florets which form the disk, and female half florets which make the rays; these are contained in one oblong scaly empalement. The hermaphrodite florets are funnel-shaped, and cut at the top into five parts; these have five short hairy stamina, terminated by cylindrical summits; they have a small germen, crowned with down, which is longer than the petal. Upon the germen sits a slender style the length of the down, crowned by two oblong stigmas; the germen afterward becomes a small oblong seed, crowned with long down. The female half florets, which compose the rays, have one side of their petals stretched out like a tongue; these have no stamina, but a small downy germen, supporting a slender style, which is hairy, crowned by two slender stigmas. The germen afterward becomes a seed like the hermaphrodite florets.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, which includes the plants with a compound flower, composed of hermaphrodite and female flowers, which are both fruitful. To this genus Dr. Linnæus has added several species of Conyza and Aster of former botanists.

The SPECIES are,

1. ERIGERON (*Viscosum*) pedunculis unifloris lateralibus foliis lanceolatis denticulatis calycibus squarrosis, corollis radiatis. Hort. Upsal. 258. Groundsel with one flower on a foot-stalk, proceeding from the side of the stalk, spear-shaped leaves, and a rough empalement. Conyza mas Theophrasti, major Dioscoridis. C. B. P. 265. Male Fleabane of Theophrastus, and greater Fleabane of Dioscorides.
2. ERIGERON (*Acre*) pedunculis alternis unifloris. Hort. Cliff. 407. Groundsel with alternate foot-stalks having one flower. Conyza cærulea acris. C. B. P. 265. Blue acrid Fleabane.
3. ERIGERON (*Bonariense*) foliis basi revolutis. Lin. Sp. Plant. 863. Groundsel whose leaves are curved at their base. Senecio Bonariensis purpurascens, foliis imis coronopi. Hort. Elth. 344. tab. 257. Purplish Groundsel of Buenos Ayres, with under leaves like Hartshorn Plantain.
4. ERIGERON (*Canadense*) caule floribusque paniculatis. Hort. Cliff. 407. Groundsel with a paniculated stalk and flowers. Virga aurea Virginiana annua. Zan. Hist. 205. Annual Virginia Golden Rod.
5. ERIGERON (*Alpinum*) caule subbifloro, calyce subhirsuto. Lin. Sp. Plant. 864. Groundsel with two flowers on a stalk, and hairy empalements. Conyza cærulea Alpina. C. B. P. 265. Blue Alpine Fleabane.
6. ERIGERON (*Graveolens*) ramis lateralibus multifloris, foliis lanceolatis integerrimis, calycibus squarrosis. Amœn. Acad. 4. p. 290. Groundsel with many flowers on the side of the stalks, entire spear-shaped leaves, and rough empalements. Virga aurea minor, foliis glutinosi & graveolentibus.
7. ERIGERON (*Fetidum*) foliis lanceolato-linearibus retusis, floribus corymbosis. Lin. Sp. 1213. Groundsel with linear spear-shaped leaves, and flowers in a corymbus. Senecio Africanus folio retuso. Herm. 661.

The first sort grows naturally in the south of France, and in Italy. This hath a perennial root, from which arise several upright stalks near three feet high, garnished with oblong oval leaves which are hairy, and sit close to the stalk; they are placed alternate, and are four inches long, and two broad in the middle; these in warm weather sweat out a clammy juice. The flowers are produced single upon pretty long foot-stalks; some arising from the side of the stalk, and others

others terminate it; they are yellow, and have an agreeable odour. They flower in July, and the seeds ripen in autumn.

This plant is propagated by seeds, which, if sown in autumn, will more certainly succeed than those which are sown in the spring. When the plants come up, they should be thinned if they are too close, and kept clean from weeds till autumn, when they should be transplanted where they are to remain. They delight in a dry soil and a sunny exposure. The second year the plants will flower and perfect their seeds, but the roots will continue several years, and annually produce their flowers and seeds.

The next four sorts are preserved in botanic gardens for the sake of variety, but are seldom admitted into gardens for pleasure. The fifth sort is a perennial plant, which grows naturally on the Alps, and may be propagated by seeds in the same manner as the first sort, but should have a shady situation and a moist soil.

The others are annual plants, which, if once admitted into a garden, and suffered to scatter their seeds, will become very troublesome weeds there.

The sixth sort rises with stiff stalks three feet high, garnished with narrow spear-shaped leaves; the flowers are yellow, and are produced in close bunches from the side of the stalk toward the top; these appear in July, and in warm seasons are succeeded by seeds in England.

It may be propagated by cutting the stalk in proper lengths, which, if planted in a shady border, and duly watered, will put out roots; and the following autumn, these may be taken up and planted in the borders of the flower-garden.

The seventh sort grows naturally in Africa: the roots of this send up five or six upright stalks near four feet high, closely garnished with linear spear-shaped leaves which are hairy; the stalks are terminated by pretty large bunches of yellow flowers, formed in a corymbus. These appear in October, and frequently continue more than two months, which renders the plant more valuable.

This is too tender to thrive in the open air in this country, so the plants should be kept in pots; and if in the winter they are placed in a common frame, where they may have a large share of free air in mild weather, and screened from hard frosts, they will thrive better than with tender treatment. It is easily propagated by cuttings, which, if planted in May, will readily put out roots, and the young plants will flower the autumn following.

ERINUS. Lin. Gen. Plant. 689. Ageratum. Tourn. Infl. R. H. 651. tab. 422.

The CHARACTERS are,

The flower hath a permanent empalement, composed of five leaves, which are equal; it hath one petal which is tubulous, and of the ringent kind; cut into five equal segments, which spread open, three standing upward from the upper lip, and two turn downward. It hath four stamina situated within the tube, two of which are a little longer than the other, terminated by small summits. In the bottom of the tube is situated the oval germen, supporting a short style, crowned by a head-shaped stigma. The germen afterward becomes an oval capsule, covered by the empalement, having two cells filled with small seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, which includes those plants whose flowers have two long and two short stamina, and their seeds growing in a capsule. Tournefort has it in his appendix, but it should be placed in his third class, and the fifth section, which contains the plants with an anomalous tubulous flower of one leaf.

The SPECIES are,

1. ERINUS (*Alpinus*) floribus racemosis. Lin. Sp. Plant. 630. *Erinus with branching flowers.* Ageratum serratum, Alpinum, glabrum, flore purpureo. Tourn. R. H. 651. *Smooth sawed Alpine Ageratum, having a purplish flower.*
2. ERINUS (*Tomentosus*) tomentosus, caulibus procum-

bentibus, floribus sessilibus axillaribus. *Woolly Erinus with trailing stalks, and flowers sitting close to their sides.* Ageratum Americanum procumbens, gnaphalii facie, floribus ad foliorum nodos. Houst. MSS. *Trailing American Ageratum with the appearance of Cudweed, and flowers growing at the knots of the leaves.*

3. ERINUS (*Americanus*) caule erecto, foliis lanceolatis oppositis, floribus laxè spicatis terminalibus. *Erinus with an upright stalk, spear-shaped leaves placed opposite, and flowers growing in loose spikes, terminating the stalks.* Ageratum Americanum erectum spicatum, flore purpureo. Houst. MSS. *Upright American Ageratum with spikes of purple flowers.*

4. ERINUS (*Frutescens*) caule erecto fruticoso, foliis ovato-lanceolatis serratis, alternis, floribus axillaribus. *Erinus with a shrubby erect stalk, oval, spear-shaped, sawed leaves placed alternate, and flowers on the sides of the stalk.* Ageratum frutescens, foliis dentatis latioribus, villosum. Houst. MSS. *Shrubby hoary American Ageratum with broad indented leaves.*

5. ERINUS (*Verticillatus*) caule ramoso procumbente, foliis ovatis serratis glabris oppositis, floribus verticillatis. *Erinus with a branching trailing stalk, oval, smooth, sawed leaves placed opposite, and flowers growing in whorls round the stalks.* Ageratum Americanum procumbens, foliis subrotundis serratis glabris. Houst. MSS. *Trailing American Ageratum with roundish, smooth, sawed leaves.*

6. ERINUS (*Procumbens*) caulibus procumbentibus, foliis ovatis glabris, floribus singulis alaribus, pedunculis longioribus. *Erinus with trailing stalks, oval smooth leaves, and single flowers on the sides of the stalks, having longer foot-stalks.* Ageratum Americanum, procumbens, glabrum, floribus luteis, longis pediculis insidentibus. Houst. MSS. *Smooth trailing American Ageratum, with yellow flowers sitting upon long foot-stalks.*

The first sort grows naturally upon the Alps and Helvetian mountains: this is a very low plant, whose leaves lie close to the ground, growing in close tufts; they are about half an inch long, and one eighth of an inch broad, sawed on their edges, and of a dark green; between these arises the flower-stalk, which is scarce two inches high, supporting a loose bunch of purple flowers, which stand erect. These appear in May, and sometimes are succeeded by ripe seeds in July.

It is propagated by parting the roots; the best time for this is in autumn; they must have a shady situation and a loamy soil without dung, for in rich earth these plants are very subject to rot.

The second sort was sent me by the late Dr. Houstoun from La Vera Cruz, where he found it growing naturally. This sends out several trailing stalks about six inches long, which are closely garnished with small oval leaves, placed on every side; they are very white and woolly, and at the joints just above the leaves come out the flowers, sitting very close to the stalks; these are white, and are succeeded by round capsules, having two cells, filled with small seeds: this plant has great resemblance at a distance to the Sea Cudweed.

The third sort was discovered by Dr. Houstoun, in the same country with the former: this hath an upright stalk two feet high, garnished with spear-shaped leaves placed opposite; and toward the top of the stalk is produced two smaller branches placed opposite, which stand erect; and these, as also the middle stalk, are terminated by loose spikes of purple flowers, which are succeeded by oval seed-vessels, filled with small seeds.

The fourth sort rises with a shrubby stalk about four feet high, dividing into several small branches, which are hairy; these are garnished with oval spear-shaped leaves, deeply sawed on their edges; they are placed alternate, and have pretty long foot-stalks. The flowers come out from the side of the stalks, sometimes single, at other times two or three at a joint, sitting close to the stalks; they are white, and are succeeded by round seed-vessels, filled with small seeds.

The

ERI

The fifth sort sends out many trailing smooth stalks, which branch out very much on every side; they grow about seven or eight inches long, and are garnished with small oval leaves placed opposite. The flowers come out in whorls, sitting very close to the stalks; they are white, and make but little appearance; these are succeeded by round capsules, filled with small seeds.

The sixth sort sends out several trailing stalks about six inches long, which divide into many smaller branches; these are garnished with small oval leaves, standing opposite. The flowers come out singly from the side of the stalk; they are of a bright yellow, and stand on long slender foot-stalks; these are succeeded by oval seed-vessels, filled with small seeds.

The fourth sort is a perennial shrubby plant, which will continue several years, if kept in a warm stove; but the second, third, fifth, and sixth sorts are annual, decaying soon after they have perfected their seeds.

These are propagated by seeds, which should be sown in pots filled with light earth, and plunged into a moderate hot-bed, where sometimes the plants will come up in five or six weeks, and at other times the seeds do not vegetate till the following spring; this happens frequently when the seeds have been kept long after they were gathered. When the plants are fit to remove, they should be each planted in a separate small pot filled with light earth, not too rich with dung, and then plunged into a hot-bed of tanners bark. When they have taken new root, they should be treated in the same way as other plants from those countries, by admitting proper air to them at all times when the weather is warm, and frequently refreshing them with water: with this management the annual sorts will flower in July and August, and frequently ripen their seeds in autumn, if the plants are brought forward early in the spring, otherwise the winter will come on before their seeds ripen.

The shrubby kind must be placed in the bark-stove in autumn, and during the winter the plants should be frequently refreshed with water, but it must not be given them in large quantities, nor too often repeated in cold weather, for moisture will then destroy them; the second year the plants will flower and perfect their seeds.

ERIOCEPHALUS. Dill. Hort. Elth. 110. Lin. Gen. Plant. 890.

The CHARACTERS are,

It hath a radiated flower, composed of female half florets which form the rays, and hermaphrodite florets, which form the disk; these are included in one common scaly empalement. The hermaphrodite florets are funnel-shaped, and cut into five parts at the brim, which spread open; these have five short hairy stamina, terminated by cylindrical summits; they have a small naked germen, supporting a single style, crowned by a pointed stigma; these are barren. The female florets have their petals stretched out on one side like a tongue, which is divided at the end into three small lobes; these have no stamina, but an oval naked germen, with a single style, crowned by an inflexed stigma; these have one naked seed, sitting on the naked plain receptacle.

This genus of plants is ranged in the fourth section of Linnæus's nineteenth class, which includes those plants with compound flowers, whose hermaphrodite florets are barren, and the female half florets are fruitful.

We know but one SPECIES of this genus, viz.

ERIOCEPHALUS (Africanus.) Lin. Sp. Plant. 926. We have no proper title for this in English. *Eriocephalus sempervirens, foliis fasciculatis & digitatis.* Hort. Elth. 132. *Evergreen Eriocephalus with fingered leaves growing in bunches.*

This plant hath a shrubby stalk, which rises from four to six feet high, putting out many side branches the whole length, closely garnished with woolly leaves, which come out in clusters; some of these are taper and entire, others are divided into three or five parts, which spread open like a hand; they have a strong smell when bruised, approaching to that of

ERU

Lavender Cotton, but not quite so rank. The flowers are produced in small clusters at the extremity of the branches, standing erect; they are tubulous. The female florets which compose the rays, form a hollow, in the middle of which the hermaphrodite flowers are situated which form the disk. The border is white, with a little reddish cast on the inside, and the disk is of a purplish colour. The flowers appear in autumn, but are not succeeded by seeds in this country.

This plant is propagated by cuttings, which may be planted any time from May to the middle of August; for if they are planted later in the season, there will not be time for them to get good root before the winter; these cuttings should be planted in small pots filled with light earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun till they have taken root; these must be refreshed with water two or three times a week, but they should not have too much at each time, for much moisture is very hurtful to these plants. When the cuttings have taken root, they should be gradually inured to the open air, to prevent their shoots from being drawn up weak; afterward they should be removed into the open air, and placed in a sheltered situation, where they may remain till October, when they must be removed into an airy glass-case, that they may have as much sun as possible, and enjoy the free air in mild weather, but secured from frost and damp air, either of which will soon destroy them. During the winter they must be sparingly watered, for the reason before given; but, in the summer, when the plants are placed in the open air, they will require to be frequently refreshed with water in hot weather.

These plants retain their leaves all the year, so they add to the variety of exotics in the winter season.

ERUCA. Tourn. Inst. R. H. 226. tab. 111. Brassica. Lin. Gen. 734. Rocket; in French, *Roquette*.

The CHARACTERS are,

The empalement of the flower is composed of four oblong leaves, which stand erect, forming a tube. The flower hath four oblong petals, placed in form of a cross, which are rounded at their ends, where they are broad, but narrow at their base, and are much longer than the empalement. It hath six stamina, four of which are a little longer than the empalement; the other two are shorter, terminated by acute segments. It hath an oblong taper germen, supporting a short style, crowned by an obtuse bifid stigma. The germen afterward becomes a taper-cornered pod with two cells, filled with roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, which includes the plants whose flowers have four long and two short stamina, and their seeds are contained in long pods. Dr. Linnæus has joined the common Rocket to his genus of Brassica, and some of the other species he has distributed under his other genera; but as the common Rocket has been long established as an officinal plant, I chuse to continue this genus by its old title.

The SPECIES are,

1. **ERUCA (Sativa)** foliis pinnato-laciniatis, laciniis exterioribus majoribus. *Rocket with wing-shaped jagged leaves, whose outer segments are the largest.* *Eruca sativa* major annua, flore albo striato. J. B. 2. 859. *Greater Garden annual Rocket with a white striped flower.*
2. **ERUCA (Bellidis folia)** foliis lanceolatis, pinnato-dentatis, caule nudo simplici. *Rocket with spear-shaped leaves which are indented, and a naked single stalk.* *Eruca bellidis-folio.* Mor. Hist. 2. 231. *Rocket with a Daify leaf.*
3. **ERUCA (Perennis)** foliis pinnatis glabris, caule ramoso, floribus terminalibus. *Rocket with winged smooth leaves, and a branching stalk terminated by flowers.* *Eruca tenuifolia perennis,* flore luteo. J. B. 2. 861. *Narrow-leaved perennial Rocket with a yellow flower.*

ERU

4. ERUCA (*Aspera*) foliis dentato-pinnatifidis hirsutis, caule hispido, siliquis lævibus. *Rocket with indented, wing-pointed, hairy leaves, a rough stalk, and smooth pods.* Eruca sylvestris, major, lutea, caule aspero. C. B. P. 98. *Greater wild Saffron-coloured Rocket with a rough stalk.*
5. ERUCA (*Tenacetifolia*) foliis pinnatis, foliolis lanceolatis pinnatifidis. Prod. Leyd. 342. *Rocket with winged leaves, whose lobes are spear-shaped and wing-pointed.* Eruca Tenacetifolia. H. R. Par. *Rocket with a Tansey leaf.*
6. ERUCA (*Viminia*) foliis sinuato-pinnatis, sessilibus, caule ramoso. *Rocket with wing-shaped sinuated leaves sitting close to the stalks, which are branching.* Eruca Sicula bursæ pastoris folio. C. B. P. 98. *Sicilian Rocket with a Shepherd's Purse leaf.*

The first sort is an annual plant, which was formerly much cultivated in the gardens as a salad herb, but at present is little known here, for it has been long rejected on account of its strong ungrateful smell. It stands in the list of medicinal plants, but at present is seldom used, though it is reckoned a provocative and a good diuretic. If it is propagated for salads, the seeds should be sown in drills, in the same manner as is usually practised for other small salad herbs; for it must be eaten young, otherwise it will be too strong for most palates. The winter and spring seasons are the times when this herb is used; for when it is sown in the summer, the plants soon run up to seed, and are then too rank. Where it is cultivated for the seed, which is sometimes used in medicine, they should be sown in March, on an open spot of ground; and when the plants have put out four leaves, the ground should be hoed to destroy the weeds, and the plants must be thinned, so as to leave them three or four inches asunder; and in about five or six weeks after, the ground should be a second time hoed to destroy the weeds, which, if well performed, will prevent them from growing to injure the plants, till the seeds are ripe; when the plants should be drawn up, and spread upon a cloth in the sun for two or three days to dry, then the seeds may be beaten out of the pods, and put up for use.

The second sort grows naturally in the south of France and Italy, where it is often eaten as a salad herb; this hath many spear-shaped leaves arising from the root, which are four or five inches long, and one inch broad in the middle, regularly indented on their edges, and spread on the ground; the stalks are single, and rise about a foot high; they are naked, seldom having more than one leaf, which is situated at the bottom; the flowers grow in loose bunches on the top of the stalks, which are succeeded by pods two inches long, having two cells filled with small round seeds. This is an annual plant, which may be propagated by seeds in the same manner as the former. The third sort grows naturally about Paris, and in many other parts of Europe; the leaves of this are narrow, and regularly divided like a winged leaf; the stalks branch out upward, and are terminated by loose spikes of yellow flowers. This hath a perennial root, and an annual stalk.

The fourth sort grows naturally upon old walls and buildings in many parts of England, where it continues flowering all the summer, but is rarely admitted into gardens. It is sometimes used in medicine, for which reason I have here mentioned it.

The fifth sort grows naturally about Turin, from whence I received the seeds. This hath fine divided leaves, somewhat like those of Tansey, but are of a hoary green colour; the stalks rise a foot and a half high, which are fully garnished with leaves of the same form, but gradually diminish in their size upward; the flowers are produced in clusters at the top of the stalks, they are small, and of a pale yellow colour; these are succeeded by slender taper pods two inches long, which contain two rows of small round seeds.

The sixth sort grows naturally in Italy and Spain; this is an annual plant, with many oblong leaves, which are smooth and regularly sinuated on their sides,

ERV

in form of a winged leaf; they are five or six inches long, and one inch and a half broad, of a light green, having a hot biting taste; the stalks rise about a foot high, they are strong, and divide into several branches; these are garnished with a single leaf at each joint, shaped like those below, but smaller. The flowers are produced in loose clusters at the end of the branches; these are white, and near as large as those of the Garden Rocket, and are succeeded by taper pods three inches long, containing two rows of round seeds. These plants are preserved in some gardens for the sake of variety, therefore they are here mentioned; and those who are inclined to cultivate them, may do it by sowing their seeds on a bed of light earth in an open situation; and when the plants come up, they will require no other culture but to thin them, and keep them clear from weeds. They flower in June and July, and their seeds ripen in August.

ERUCAGO. See BUNIAS.

ERVUM. Lin. Gen. Plant. 784. Tourn. Inst. R. H. 398. tab. 221. *Bitter Vetch.*

The CHARACTERS are,

The empalement of the flower is divided into five equal parts, which end in acute points; the flower is of the butterfly kind, having a large, roundish, plain standard, two obtuse wings half the length of the standard, and a shorter keel which is pointed. It hath ten stamina, nine joined, and one standing separate, terminated by single summits. It hath an oblong germen, supporting a rising style, crowned by an obtuse stigma. The germen afterward becomes an oblong taper pod, jointed between each seed.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes those plants with a butterfly flower, with ten stamina separated in two bodies. To this genus Dr. Linnæus has joined the Lens of Tournefort, and some species of Vicia. The difference which he makes between Vicia and Ervum is only in their stigmas, that of Vicia having an obtuse stigma, bearded on the under side, and that of the Ervum is smooth.

The SPECIES are,

1. ERVUM (*Ervilia*) germinibus undato-plicatis foliis impari pinnatis. Hort. Upsal. 224. *Ervum whose germen are waved and folded, and unequal winged leaves.* Ervum verum. Camer. Hort. *The true Bitter Vetch.*
 2. ERVUM (*Lens*) pedunculis subbifloris seminibus compressis convexis. Lin. Sp. Plant. 738. *Ervum with foot-stalks having two flowers, and compressed seeds which are convex.* Lens vulgaris. C. B. P. 346. *Common Lentils.*
 3. ERVUM (*Monanthos*) pedunculis unifloris. Lin. Sp. Plant. 738. *Ervum with one flower on each foot-stalk.* Lens monanthos. H. L. 360. *One flowered Lentil.*
 4. ERVUM (*Tetraspermum*) pedunculis subbifloris, seminibus globosis quaternis. Flor. Suec. 606. *Ervum with two flowers on each foot-stalk, and four globular seeds in each pod.* Vicia segetum singularibus siliquis glabris. C. B. P. 345. *Corn Vetch with single smooth pods.*
 5. ERVUM (*Hirsutum*) pedunculis multifloris, seminibus globosis binis. Lin. Sp. Plant. 738. *Ervum having many flowers on a foot-stalk, and two globular seeds in each pod.* Vicia segetum, cum siliquis plurimis hirsutis. C. B. P. 345. *Corn-Vetch having many hairy pods.*
- The first sort grows naturally in Italy and Spain: it is an annual plant, which rises with angular weak stalks a foot and a half high, garnished at each joint with one winged leaf, composed of fourteen or fifteen pair of lobes, very like those of the Vetch, but narrower; the flowers come out from the side of the stalks, on foot-stalks an inch long, each sustaining two pale-coloured flowers, which are succeeded by short pods a little compressed, each having three or four round seeds; the pods swell at the place where each seed is lodged, so that it is called a jointed pod by many. The seeds of this plant ground to flour is sometimes used in medicine; and the green herb is used for feeding of cattle in some countries, but it is not worth cultivating for that purpose in England. The second sort is the common Lentil, which is cultivated in many parts of England, either as fodder

for cattle, or for the seeds, which are frequently used for meagre soups. This is also an annual plant, and is one of the least of the pulse kind, which is cultivated: it rises with weak stalks a foot and a half high, garnished with winged leaves at each joint, composed of several pair of narrow lobes, terminated by a tendril or clasper, which fastens to any neighbouring plant, and is thereby supported; the flowers come out upon short foot-stalks from the side of the branches; they are small, of a pale purple colour, three or four standing upon a foot-stalk; these are succeeded by short flat pods, containing two or three seeds, which are flat, round, and a little convex in the middle. The flowers appear in May, and the seeds ripen in July. The seeds of this plant are commonly sown in March, where the land is dry, but in moist ground the best time is in April. The usual quantity of seed allowed to an acre of land, is from one bushel and a half to two bushels. If these are sown in drills in the same manner as Peas, they will succeed better than when they are sown in broad cast: the drills should be a foot and a half asunder, to allow room for the Dutch hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the Lentils and starve them. The seeds of these will ripen in July, when the plants should be cut and dried, and afterward the seeds should be threshed out for use.

The seeds of Lentils are frequently the common food of the poorer sort of people in some of the islands of the Archipelago, and other warm countries, when they can meet with no better fare; for these they loath, when they have better food, from whence came the proverb, *Dives factus jam dist gaudere lente*; which is applied to those who spurn at those things in easy circumstances, which they were glad of in a low condition.

There is another sort of Lentil which has been cultivated of late years in England, by the title of French Lentil. This is the *Lens major* of Caspar Bauhin, and is undoubtedly a different species from the common, being twice the size, both in plant and seed, and constantly produces the same from seeds, though they do not differ much in their characters, but this is much better worth cultivating than the other. This pulse is frequently called Tills in many parts of England.

The third sort is very like the common Lentil, but differs from it, in having but one flower on each foot-stalk, whereas the other has three or four, but in other respects is the same, so may be cultivated in the same manner.

The fourth and fifth sorts are small annual Vetches, which grow naturally among the Wheat and Rye in many parts of England, so are not admitted into gardens; they are only mentioned here as weeds, which may be easily rooted out of the fields, if they are cut up when they begin to flower, and not permitted to ripen their seeds; for as they have annual roots, so if they do not scatter their seeds, they may be soon destroyed.

ERYNGIUM ORIENTALE. See SOPHORA.

ERYNGIUM. Lin. Gen. Plant. 287. Tourn. Inst. R. H. 327. tab. 173. Sea Holly, or Eryngo.

The CHARACTERS are,

It hath many small flowers sitting upon one common conical receptacle; whose involucre is composed of several plain leaves; the flowers have a five-leaved erect empalemt, coloured on the upper side, sitting upon the germen; these form a roundish general umbel, which is uniform. The flowers have five oblong petals, which are turned inward at top and bottom, and five erect hairy stamina, standing above the flowers; terminated by oblong summits; under the empalemt is situated a prickly germen, supporting two slender styles, crowned by single stigmas. The germen afterward becomes an oval fruit divided in two parts, each having one oblong taper seed.

This genus of plants is ranged in the second section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and two styles.

The SPECIES are,

1. ERYNGIUM (*Maritimum*) foliis radicalibus subrotundis plicatis spinosis, capitulis pedunculatis. Hort. Cliff. 87. *Sea Holly whose lower leaves are folded, roundish, and prickly, and flower-heads having foot-stalks.* Eryngium maritimum. C. B. P. 386. *Sea Holly, or Eryngo.*
2. ERYNGIUM (*Campestre*) foliis amplexicaulibus pinnato laciniatis. Hort. Cliff. 87. *Sea Holly whose leaves embrace the stalks, and are cut like winged leaves.* Eryngium vulgare. C. B. P. 386. *Common Eryngo.*
3. ERYNGIUM (*Planum*) foliis radicalibus ovalibus planis crenatis, capitulis pedunculatis. Hort. Cliff. 87. *Sea Holly whose lower leaves are plain, oval, and crenated, with flower-heads having foot-stalks.* Eryngium latifolium planum. C. B. P. 386. *Broad-leaved plain Eryngo.*
4. ERYNGIUM (*Amethystinum*) foliis trifidis basi subpinnatis. Lin. Sp. Plant. 337. *Eryngo with trifid leaves, and those at the base winged.* Eryngium montanum amethystinum. C. B. P. 386. *Purple Violet-coloured Mountain Eryngo.*
5. ERYNGIUM (*Pallescente*) foliis radicalibus rotundato-multifidis, capitulis pedunculatis. *Eryngo whose lower leaves are roundish and multifid, having foot-stalks to the heads of flowers.* Eryngium Alpinum amethystinum, capitulo majore pallescente. Tourn. Inst. 328. *Alpine Eryngo with a large pale-coloured head.*
6. ERYNGIUM (*Orientale*) foliis radicalibus pinnatis, serrato-spinosis, foliolis trifidis. *Eryngo whose lower leaves are winged, spiny indented, and the smaller ones trifid.* Eryngium Orientale, foliis trifidis. T. Cor. 23. *Oriental Eryngo with trifid leaves.*
7. ERYNGIUM (*Aquaticum*) foliis gladiatis serrato-spinosis, floralibus indivisis caule simplici. Lin. Sp. Plant. 336. *Eryngo with sword-shaped leaves which are spiny and indented, and the upper ones entire.* Eryngium foliis gladiolatis utrinque laxè serratis, denticulis subulatis. Lin. Hort. Cliff. 88. *American Sea Holly with leaves like the Aloe, lightly sawed, commonly called Rattlesnake Weed in America.*
8. ERYNGIUM (*Pusillum*) foliis radicalibus oblongis incisis, caule dichotomo, capitulis sessilibus. Hort. Cliff. 87. *Eryngo with oblong lower leaves which are cut, a stalk divided by pairs, and heads sitting close.* Eryngium planum minus. C. B. P. 386. *Lesser plain Eryngo.*
9. ERYNGIUM (*Alpinum*) foliis radicalibus cordatis oblongis, caulinis pinnatifidis, capitulo subcylindrico. Lin. Sp. Plant. 233. *Eryngo with oblong, heart-shaped, lower leaves, those upon the stalks wing-pointed, and cylindrical heads.* Eryngium Alpinum cæruleum, capitulis dispati. C. B. P. 386. *Blue Alpine Eryngo with heads like the Teasel.*
10. ERYNGIUM (*Fetidum*) foliis radicalibus subensiformibus serratis floralibus multifidis caule dichotomo. Lin. Sp. Plant. 336. *Eryngo with sword-shaped lower leaves having spiny saws, the upper leaves ending in many points.* Eryngium foliis angustis serratis foetidum. Sloan. Cat. Jam. 127. *Stinking Eryngo having narrow sawed leaves, commonly called Feverweed.*

The first of these species grows in great plenty on the sandy and gravelly shores in divers parts of England, the roots of which are candied, and sent to London for medicinal use, and is the true Eryngo. This hath creeping roots, which run deep into the ground; the leaves are roundish, stiff, and of a gray colour, set with sharp spines on the edges. The stalks rise a foot high, and divide upward into two or three smaller branches; they are smooth, and garnished at each joint with leaves of the same form as the lower, but smaller, which embrace the stalks with their base; at the end of the branches come out the flowers in roundish prickly heads; under each is situated a range of narrow, stiff, prickly leaves, spreading like the rays of a star; the flowers are of a whitish blue colour. They appear in July, and the stalks decay in autumn.

This sort will grow in a garden, if the roots are planted in a gravelly soil, and produce their flowers annually; but the roots will not grow near so large or fleshy as those which grow on the sea-shore, where they are flowed with salt water. The best time to transplant the roots is in autumn, when their leaves decay;

decay; the young roots are much better to remove than the old, because they are furnished with fibres, so will readily take root: when these are fixed in the ground, they should remain unremoved; and if they are kept clean from weeds, it is all the culture they will require.

The second sort grows naturally in several parts of England, where it is a very troublesome weed, for the roots run deep into the ground, so are not easily destroyed by the plough; and they spread and multiply greatly in the ground, to the prejudice of whatever is sown or planted on the land, therefore it is not admitted into gardens.

The third sort makes a very pretty appearance when it is in flower, especially that with the blue stalks and flowers, for there is a variety of this with white flowers and stalks; but as this doth not spread at the root, but keeps within bounds, so a few of the plants should be allowed a place in the pleasure-garden. This is propagated by seeds, which, if sown in the autumn, will more certainly succeed than when it is sown in the spring, for the latter commonly remains in the ground a year before they vegetate; and if the seeds are sown where the plants are to remain, they will flower stronger than those which are transplanted; for as they have long downright roots, so these are commonly broken in taking out of the ground, which greatly weaken the plants. The culture they require is to thin them where they are too near, keep them clean from weeds, and dig the ground about them every spring before they shoot.

The stalks of this sort will rise from two to three feet high, the lower leaves are oval and plain; those of the white sort are of a lighter green than those of the blue; the upper part of the stalks of the white are of that colour, those of the blue are of the colour of amethyst; the stalks divide upward, where they are garnished with leaves divided into many points ending with spines; the flowers are produced in oval heads at the top of the stalk, standing upon separate foot-stalks. The flowers come out in July, and the seeds ripen in September.

The fourth sort grows naturally upon the mountains of Syria, and also upon the Apennines. The lower leaves of this sort are divided like the fingers of a hand, into five or six segments, which are very much cut at their extremities into many parts, and have small spines; the stalk rises about two feet high, garnished with smaller and more divided leaves; the upper part of the stalk, and also the heads of flowers, are of the finest amethyst colour, so that they make a very fine appearance. This sort flowers in July, and when the autumn proves dry, their seeds will ripen in September, but in wet seasons the seeds never ripen in England. This is propagated by seeds in the same manner as the former sort.

The fifth sort has been supposed by many, to be only a variety of the fourth; but I have propagated it by seeds more than thirty years, without finding the least alteration, so that I make no doubt of its being a distinct species. The lower leaves of this are very much divided, and the extremity of the segments form an oval or circle; these are divided into many fine parts, which end in spines; they are of a whitish gray in the middle, and green on the borders. The stalks rise about two feet high, garnished at the joints with smaller leaves which are finely cut; the flowers terminate the stalk, they are of a light blue colour, and grow in larger heads than either of the former sorts. It flowers in June and July, and the seeds ripen in autumn. This grows naturally on the Alps; it is a perennial plant, and may be propagated by seeds in the same manner as the former.

The sixth sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the royal garden at Paris. This hath a perennial root, the lower leaves are regularly divided into seven or nine parts to the midrib, as the other winged leaves; these segments are sawed on their edges, which end in sharp thorns. The stalks rise two feet high,

sending out side branches, garnished with stiff leaves, which are divided into narrower segments than the lower, and are terminated by three points. The flowers terminate the stalks, sitting close among the leaves, and are of a fine blue, as are also the leaves on the upper part of the stalks, so they make a pretty appearance. This flowers in July, but seldom ripens seeds in England. It is propagated in the same manner as the three former sorts, and the plants require the same treatment.

The seventh sort grows naturally in Virginia and Carolina, where it is titled Rattlesnake Weed, from its virtues of curing the bite of that venomous reptile. This hath a perennial root, from which arise several long leaves, which are sawed on their edges, ending in spines; these leaves are disposed round the root, after the same form of the Aloe or Yucca; they are of a gray colour, a foot long or more, and one inch and a half broad, stiff, and end in spines. The stalk is strong, grows two feet high, dividing upward into several foot-stalks, each being terminated by an oval head of flowers, shaped like those of the former sorts; they are white, with a little cast of pale blue. This sort flowers in July, but unless the season is very warm, the seeds will not ripen in England.

This sort is propagated by seeds, which, if sown in pots and plunged into a moderate hot-bed, the plants will come up much sooner than those which are sown in the full ground, whereby they will be much stronger before the winter. When the plants are fit to remove, they should be each planted in a separate small pot, filled with light earth; and if they are plunged into a moderate hot-bed, it will forward their taking root; then they must be gradually inured to bear the open air, into which they may be removed toward the latter end of May, and placed among other hardy exotic plants. When the plants have filled these pots with their roots, some of them may be shaken out, and planted in a warm border; the others may be put into larger pots, and in the autumn placed under a common frame, where they may be exposed to the free air in mild weather, but sheltered from severe frost: the following spring these may be turned out of the pots, and planted in a warm situation, where they will endure the cold of our ordinary winters very well; and if in severe frost they are covered with Straw, Peas-haulm, or any such light covering, it will secure them from injury.

The eighth sort grows naturally in Spain and Italy. This puts out oblong plain leaves from the root, which are cut on their edges; the stalks rise about a foot high, and branch out into many forked divisions, which are regular, and at each of these divisions is situated a small head of flowers, sitting very close between the branches. These have no great beauty, so the plants are seldom cultivated in gardens, except for the sake of variety.

The ninth sort grows naturally on the mountains of Helvetia and Italy. The root is perennial, the lower leaves are oblong, heart-shaped, and plain; the stalks rise from two to three feet high, branching out on their sides upward; these are garnished with stiff leaves, which are deeply divided, ending in many points with sharp spines; the flowers terminate the stalks, they are collected into conical heads, and are of a light blue colour, as are also the upper part of the stalks. This flowers in July, and the seeds are ripe in September; it is propagated by seeds in the same manner as the other sorts.

The tenth sort grows naturally in the West-Indies, where it is much used in medicine, being accounted of great service in the cure of fevers, from whence it hath the appellation of Feverweed in those countries. The roots of this plant are composed of many small fibres, which spread near the surface; the lower leaves are six or seven inches long; they are narrow at their base, and enlarge upward to an inch in breadth near the top, where they are rounded off on one side like a scymitar; they are finely sawed on their edges, and are of a light green colour; the stalk rises about a foot

foot high, and spreads out into many branches, garnished with small leaves, which end in many points; the flowers are produced in small heads which sit close to the stalks, coming out at every division of the stalks, and at the end of the branches; these are of a dull white colour, so make little appearance. They appear in June and July, and the seeds ripen in autumn. As this plant is a native of hot countries, so it will not thrive in England, but in a warm stove. It is propagated by seeds, which must be sown on a hot-bed; and when the plants are fit to remove, they should be each planted into a small pot, and plunged into the bark-bed, and afterward treated like other tender plants from the same country; the second year they will produce flowers and seeds, soon after which they commonly decay.

ERYSIMUM. Lin. Gen. Plant. 729. Tourn. Inst. R. H. 228. tab. 111. [*Ἐρύσιμον*, of *ἐρύω*, Gr. to draw out, because this plant, by means of its hot quality, has the quality of drawing any thing out of the body in which it lies hid.] Hedge-Mustard; in French, *Velar*, or *Tortelle*.

The CHARACTERS are,

The empalement of the flower is composed of four oblong, oval, coloured leaves; the flower hath four petals, placed in form of a cross; these are oblong, plain, and obtuse; it hath two nectarious glands, situated between the stamina. It hath six stamina, four of which are the length of the empalement, the other two are a little shorter, terminated by single summits. It hath a very narrow four-cornered germen as long as the stamina, with a short style, crowned by a small permanent stigma; the germen afterward becomes a long, narrow, four-cornered pod with two cells, filled with small round seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, which includes those plants whose flowers have four long and two short stamina, and the seeds are included in long pods.

The SPECIES are,

1. **ERYSIMUM (Officinale)** siliquis spicæ adpressis foliis runcinatis. Hort. Cliff. 337. *Hedge Mustard whose pods are pressed close to the spikes. Erysimum vulgare.* C. B. P. 100. *Common Hedge Mustard.*
2. **ERYSIMUM (Barbarea)** foliis lyratis extimo subrotundo. Flor. Suec. 557. *Hedge Mustard with harp-shaped leaves, the outer segment being roundish. Sisymbrium erucæ folio glabro flore.* Tourn. Inst. 226. *Winter Cress with a Rocket leaf and yellow flower.*
3. **ERYSIMUM (Vernum)** foliis radicalibus lyratis, caulinis pinnato-sinuatis, floribus laxè spicatis. *Hedge Mustard with lower leaves shaped like a harp, those on the stalks sinuated and winged, and flowers growing in loose spikes. Sisymbrium erucæ folio glabro minus & præcocius.* Tourn. Inst. 226. *Smaller early Winter-Cress with a smooth Rocket leaf.*
4. **ERYSIMUM (Orientale)** foliis radicalibus ovatis integerrimis, petiolis decurrentibus, caulinis oblongis dentatis sessilibus. *Hedge Mustard with lower leaves oval and entire, a winged foot-stalk, and the leaves upon the stalks oblong, indented, and sitting close. Sisymbrium Orientale barbæræ facie, plantaginis folio.* Tourn. Cor. 16. *Oriental Sisymbrium with the appearance of Water-Cress and a Plantain Leaf.*
5. **ERYSIMUM (Minus)** foliis inferioribus pinnato-sinuatis, superioribus oblongis dentatis, floribus solitariis alaribus. *Hedge Mustard whose lower leaves are winged and sinuated, the upper oblong and indented, and single flowers proceeding from the sides of the stalks. Sisymbrium minus erucæ folio glabro nigro, crasso lucido.* Boerh. Ind. alt. 2. 16. *Smaller Winter Cress, with a smooth, dark, thick, shining Rocket leaf.*
6. **ERYSIMUM (Alliaria)** foliis cordatis. Hort. Cliff. 338. *Hedge Mustard with heart-shaped leaves. Hesperis alium redolens.* Mor. Hist. 2. 252. *Dames Violet smelling like Garlick, commonly called Alliaria, Sauce alone, or Jack by the Hedge.*
7. **ERYSIMUM (Cheiranthoides)** foliis lanceolatis integerrimis. Flor. Lapp. 263. *Hedge Mustard with entire spear-shaped leaves. Leucoium hesperidis folio.* Tourn. Inst. 221. *Gilliflower with a Dames Violet leaf.*

The first sort is used in medicine; this grows naturally on the side of foot-paths, and upon old walls in most parts of England, so is rarely cultivated in gardens, where, if it is once admitted, will soon become a troublesome weed.

The second and third sorts also grow naturally on the banks in most parts of England; these were formerly eaten in winter sallads, before the English gardens were furnished with better plants; since when they have been rejected, for they have a rank smell, and are disagreeable to the palate.

The fourth and fifth sorts are not natives of this country, but since they have been introduced into some English gardens, they have propagated themselves by their scattered seeds in so plentiful a manner, as to become troublesome weeds. These have a resemblance of the common Winter Cress, but the lower leaves of the fourth sort are entire, and of an oblong form; the upper leaves are oblong and indented, in which this differs.

The fifth sort hath thicker leaves, which are of a dark lucid green colour, and the flowers come out single from the wings of the stalk the whole length. These differences are lasting, and do not alter.

The sixth sort grows naturally on the sides of banks in many parts of England, so is not suffered to have a place in gardens. This was formerly eaten as a sallad herb by the poorer sort of people, who gave it the title of Sauce alone. This hath a rank smell and taste of Garlick, and is very biting and hot on the palate; it is frequently prescribed in medicine.

The seventh sort is sometimes found growing naturally upon old walls in some parts of England, particularly at Cambridge and Ely, at both which places I have observed it. This hath pretty long, hairy, soft leaves at the root; the stalks rise near a foot high, their upper part being garnished with small greenish white flowers in loose spikes; these are succeeded by long compressed pods which hang downward. It flowers in May, and the seeds ripen in July and August; but the roots will abide several years, if they have a dry lean soil, or grow upon a wall, for in rich land they soon decay.

The other sorts are sometimes kept in botanic gardens for the sake of variety; they are biennial plants, which perish after they have perfected their seeds. These may be propagated by sowing their seeds in the autumn, in the places where they are to remain, and require no other culture but to thin them, and keep them clear from weeds.

ERYTHRINA. Lin. Gen. Plant. 762. Corallodendron. Tourn. Inst. R. H. 661. tab. 446. Coral-tree.

The CHARACTERS are,

The flower hath a tubulous empalement of one leaf, which is entire and indented at the brim. The flower is of the butterfly kind, composed of five petals; the standard is spear-shaped, and deflexed on the styles; it is very long, and rises upward; the two wings are scarce longer than the empalement, and are oval; the keel is composed of two petals which are no longer than the wings, and are indented at the top; it hath ten stamina which are joined below, and are a little curved, about half as long as the standard, and are unequal in their length, terminated by arrow-pointed summits; it hath an awl-shaped germen with a foot-stalk, narrowed at the style, which is the length of the stamina, terminated by a single stigma. The germen afterward becomes a long swelling pod ending in an acute point, having one cell, filled with kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes the plants with a butterfly flower, having ten stamina joined in two bodies.

The SPECIES are,

1. **ERYTHRINA (Herbacea)** foliis ternatis, caule simplicissimo inermi. Hort. Cliff. 354. *Erythrina with trifoliate leaves, and a single smooth stalk. Corallodendron humile, spicâ florum longissimâ, radice crassissimâ.* Cateeb. Carol. 49. tab. 49. *Low Coral-tree with a very*

long spike of flowers and thick root, commonly called the Carolina Coral-tree.

2. ERYTHRINA (*Corallodendron*) inermis, foliis ternatis, caule arboreo. Smooth Erythrina with trifoliate leaves, and a tree-like stalk. Coral arbor Americana. Hort. Amst. 1. p. 211. Smooth American Coral-tree.
3. ERYTHRINA (*Spinosa*) foliis ternatis, caule arboreo aculeato. Hort. Cliff. 354. Erythrina with trifoliate leaves, and a tree-like prickly stalk. Corallodendron triphyllum Americanum, spinosum, flore ruberrimo. Tourn. Inst. R. H. 661. Prickly three-leaved American Coral-tree, with a very red flower.
4. ERYTHRINA (*Pista*) foliis ternatis aculeatis caule arboreo aculeato. Lin. Sp. 993. Erythrina with trifoliate prickly leaves, and a prickly tree-like stalk. Corallodendron triphyllum Americanum, minus spinis & seminibus nigricantibus. Tourn. Inst. R. H. 661. Smaller three-leaved American Coral-tree, with blacker spines and seeds.
5. ERYTHRINA (*Americana*) foliis ternatis acutis, caule arboreo aculeato, floribus spicatis longissimis. Erythrina with trifoliate acute-pointed leaves, a prickly tree-like stalk, and very long spikes of flowers. Corallodendron triphyllum Americanum, foliis mucronatis, seminibus coccineis. Houst. MSS. Three-leaved American Coral-tree, with acute-pointed leaves and scarlet seeds.
6. ERYTHRINA (*Inermis*) foliis ternatis acutis, caule fruticoso inermi, corollis longioribus clausis. Erythrina with acute trifoliate leaves, a shrubby unarmed stalk, and longer flowers which are closed. Coral arbor non spinosa, flore longiore & magis clauso. Sloan. Cat. Jam. 142. Coral-tree without spines, having a longer closer flower.

The first sort grows naturally in South Carolina, from whence Mr. Catesby sent the seeds in the year 1724, and many of the plants were then raised in several curious gardens. This hath a very large woody root, which seldom rises more than a foot and a half high, from which come out fresh shoots every spring; these grow about two feet high, their lower part being garnished with trifoliate leaves, of a deep green colour, which are shaped like the point of an arrow; the upper part of the stalks are terminated by a long spike of scarlet flowers, composed of five petals, the upper petal being much longer than the other, so that at a small distance the flowers appear to have but one petal. After the flowers are past, the germen turns to a taper pod five or six inches long, swelling in every part where the seeds are lodged, opening in one cell, containing five or six kidney-shaped scarlet seeds. These plants flower in England, but they never produce seeds here.

The second sort hath a thick woody stem, which rises about ten or twelve feet high in this country, but in its native country grows to twice that height, sending out many strong irregular branches, which are covered with a brown bark, garnished with trifoliate leaves standing upon long foot-stalks, the middle lobe which terminates the leaf, being much larger than the other two; they are all heart-shaped, smooth, and of a deep green colour; the flowers come out at the end of the branches, in short, thick, close spikes; they are of a deep scarlet colour, and make a fine appearance. These commonly are in beauty in May and June in this country, but are not succeeded by pods here; but in America, where the trees grow naturally, they have thick, swelling, crooked pods, which contain large kidney-shaped seeds, of a reddish purple colour. The leaves of this tree decay in the spring and fall off, so that in summer they appear to have no life; but in the autumn it puts out new leaves, which continue green all the winter. The flowers do not appear till the leaves drop, so that the branches are often naked at the time when the flowers are out.

The third sort chiefly differs from the second, in having its trunk, branches, and the foot-stalks of the leaves, armed with short crooked spines, the leaves and flowers being very like those of the second sort.

The fourth sort hath shrubby stalks, which divide into branches, and seldom rise above eight or nine

feet high; these are armed in every part with strong, crooked, black spines; the leaves are smaller than those of the two last sorts, and have a nearer resemblance of the first; the foot-stalks of the leaves are armed with the same sort of spines, and the midrib of the leaves have also some which are smaller and not so black; the flowers are of a paler scarlet, and grow in looser spikes. The seeds are as large as those of the second sort, but are of a dark purple colour.

This tree is generally planted in the East-Indies for a support to the Pepper plants, which twine round the stem and branches, whereby they are prevented trailing on the ground; and as the branches of this tree will put out roots and grow, so they are preferable to any dead props, which in those hot countries, where there is much rain, would soon rot.

The seeds of the fifth sort were sent me from La Vera Cruz, where the plants grow naturally; and since I have received seeds of the same sort from the Cape of Good Hope, so that it is a native of both countries. The seeds of this are not half so large as those of the second or third sorts, and are of a bright scarlet colour; the leaves are also much smaller, and have long acute points; the branches are very closely armed with crooked greenish spines, as are also the ribs and foot-stalks of the leaves. The flowers grow in very long close spikes, and are of a beautiful scarlet colour.

I have also raised a variety of this with paler flowers and seeds, and the plants were less thorny; but as I was doubtful of its being a distinct species, so I only mention it here.

The sixth sort grows in Jamaica, and some of the other islands in America, from whence I have received the seeds. The pods of this sort are longer, and not more than half so thick as those of the second sort; the seeds are of a bright scarlet colour, they are longer and slenderer than those of the other sorts; the leaves are small and acute-pointed, and the stalks are smooth and without spines: this doth not grow very large, but shoots out into branches at a little distance from the ground, which grow erect, so form a bushy shrub. The flowers come out at the end of the branches in short spikes; the standard of the flower is long, and the sides turn down over the wings, which are also longer than those of the other species, and the whole flower is more closed.

I have also received specimens of a variety of the third sort from the island of Barbuda, with very short flowers and pods; they came by the title of Bean-tree, which is the common appellation given to these trees in America; but the flowers were separated from the stalks, so that I can give no account in what manner they grow, whether in long or short spikes; but the stamina of these are much longer than the petals, in which it differs from all the other; the pods are very short and crooked, but are rather thicker than those of the third sort; the leaves have the same appearance, and are armed with spines, as are also the stalks and branches, but the plants have not as yet produced any flowers here.

A few years ago I received a few very small seeds of a Coral-tree from the Cape of Good Hope, which were of a bright scarlet colour; the plants have no spines on them, the leaves are much larger than the other sorts, their stems are strong, and have the appearance of growing to large trees; but as they are young, so there is no determining how they may differ from the other species.

There are two other sorts of Coral-tree mentioned by Sir Hans Sloane, in his History of Jamaica: one of which is by its characters a Sophora, under which genus we shall place it; and the other will be put under Robinia, to which genus it properly belongs.

These plants when they produce their flowers, are some of the greatest ornaments to the stoves we yet know; for their flowers are produced in large spikes, and are of a beautiful scarlet, so they make a fine appearance; but it is seldom they flower here, or in any of the northern parts of Europe; yet in the countries

countries where they naturally grow, they produce flowers in great plenty every year; so that it is very common there to see most of their branches terminated by large spikes of flowers, when they have no leaves upon them; and the first sort, which grows in Carolina, is equally productive of flowers there, tho' here they do not flower oftener than once in two or three years, and the other sorts not so frequent. I have tried by various methods to get them to flower; some I have treated hardily, by exposing them to the open air during the summer season, and in the winter kept them in a very moderate temperature of warmth; others I have kept plunged all the year in the tan-bed of the stove, and some have remained in a dry stove all the year, where in warm weather they had a large share of air admitted to them, and in winter the air was kept to the temperate point. In this last place the plants have succeeded best, yet with this treatment they seldom flower; and this is the general complaint of every one who is possessed of these plants, not only in England, but also in Holland and France.

The first sort may be kept through the winter in a warm green-house, but the plants so kept rarely flower; and the two sorts which I have received from the Cape of Good Hope, have lived through the winter in a warm glass-case, without fire; but these have not made so good progress, as those plants which were kept in a temperate warmth; so that in this country, it is much the best method of treating these plants, especially while they are young.

These plants are best propagated by seeds, when they can be procured from the countries where they naturally grow, for they do not produce any here, tho' they are annually brought to England in plenty. The seeds should be sown in small pots, and plunged into a moderate hot-bed; where, if the seeds are good, the plants will come up in a month or five weeks; when they are two inches high, they should be carefully shaken out of the pots, and each planted in a separate small pot, filled with light earth, and plunged into a moderate hot-bed of tanners bark, where they must be shaded from the sun till they have taken new root; then they should have a large share of air admitted to them at all times when the weather is warm, to prevent their being drawn up weak; and as the plants increase in strength, so they must have a larger share of air. They must be frequently refreshed with water, but not given to them in great plenty, for too much moisture will rot the fibres of their roots. In the autumn the plants should be removed into the stove; and for the two or three first winters, while the plants are young, they will require more warmth than when they have acquired more strength. During the time the leaves continue in vigour, the plants will require to have water two or three times a week; but when they are destitute of leaves, it must be sparingly given, for moisture then is very hurtful to them. As the plants grow in strength, so they must be more hardily treated; and by managing them differently, there will be a greater chance of getting them to flower. The third sort is frequently planted in the gardens near Lisbon, where they annually flower and ripen their seeds, which have been brought me by persons who gathered the pods from the trees.

These plants may also be propagated by cuttings, which, if planted in pots during the summer months, and plunged into a hot-bed, will take root, but the seedling plants are best.

ERYTHRONIUM. Lin. Gen. Plant. 375. *Dens canis*. Tourn. Inst. R. H. 378. tab. 202. Dog's Tooth, or Dog's Tooth Violet.

The CHARACTERS are,

The flower has no empalement; it is bell-shaped, and composed of six oblong petals, which spread open to their base. It hath six stamina joined to the style, terminated by oblong, erect, quadrangular summits. In the center is situated an oblong, obtuse, three-cornered germen, supporting a single style which is longer than the stamina, crowned by a triple, obtuse, spreading stigma. The germen

afterward becomes an oblong obtuse capsule with three cells, filled with flat seed.

This genus of plants is ranged in the first section of Linnæus's sixth class, in which he places those plants whose flowers have six stamina and one style.

The SPECIES are,

1. **ERYTHRONIUM** (*Dens Canis*) foliis ovatis. *Erythronium* with oval leaves. *Dens canis* latiore rotundioreque folio, flore ex purpurâ rubente. C. B. P. 87. *Dog's Tooth Violet* with a broader and rounder leaf, and a purple red flower.
2. **ERYTHRONIUM** (*Longifolium*) foliis lanceolatis. *Erythronium* with spear-shaped leaves. *Dens canis* angustiore longioreque folio, flore ex albo purpurascente. C. B. P. 87. *Dog's Tooth Violet*, with a longer and narrower leaf, and a purplish white flower.

These are the only distinct species which I have seen, but there are some varieties of them, which are preserved in curious gardens. Of the first sort there is a white flower, which is pretty common in the gardens; another with a pale purple, and a third with yellow flowers, which are rare in England; and of the second sort there is one with a white, and another with a soft red flower, both which are now very rare in the gardens.

The first sort sends out two oval leaves, which are joined at their base: they are three inches long and one and a half broad in the middle, gradually lessening toward the end; these at first embrace each other inclosing the flower, but afterward they spread flat upon the ground; they are spotted with purple and white spots all over their surface; between these rises a single naked stalk about four inches high, which is smooth, of a purple colour; this sustains one flower, composed of six spear-shaped petals, which in this are purple, but in some they are white; the flower hangs downward, and the petals reflex and spread open to their base. In the center is situated the oblong three-cornered germen, supporting a single style which is longer than the stamina, crowned by a triple stigma; the purple stamina stand close about the style, and the stigma stands farther out. This plant flowers early in April, but seldom produces seeds in England. The root of this plant is white, oblong, and fleshy, and shaped like a tooth; from whence it had the title of Dog's Tooth.

The second sort differs from the first in the shape of its leaves, which are longer and narrower, and the flowers are a little larger but not so well coloured. They grow naturally in Hungary, and in some parts of Italy. They are propagated by offsets from their roots, which they do not send out very plentifully, so they are not so commonly seen in the gardens, as most other flowers of the same season: they love a shady situation and a gentle loamy soil, but should not be too often removed. They may be transplanted any time after the beginning of June, when their leaves will be quite decayed, till the middle of September; but the roots should not be kept very long out of the ground, for if they shrink, it will often cause them to rot. The roots of these flowers should not be planted scattering in the borders of the flower-garden, but in patches near each other, where they will make a good appearance.

ESCHYNOMENE. See *ÆSCHYNOMENÆ*.

ESCHYNOMENOUS, ÆSCHYNOMENOUS PLANTS [*Αἰσχυνόμενοι*, of *αἰσχύνωμαι*, Gr. to be ashamed,] the sensitive plants; which, when one touches them, will shrink in, or let their leaves fall down.

ESCULENT PLANTS [of *esculentus*, Lat. eatable,] such plants, or the roots of them, as may be eaten; as Beets, Carrots, Leeks, Onions, Parsneps, Potatoes, Radishes, Horse-radish, Scorzoneræ, &c.

ESPALIERS, are either rows of trees planted about a whole garden or plantation, or in hedges, so as to inclose quarters or separate parts of a garden, which are trained up flat in a close hedge, for the defence of tender plants against the violence and injury of wind and weather.

The

ESP

The most commonly received notion of Espaliers are hedges of fruit-trees, which are trained up regularly to a lattice of wood work, formed either of Ash-poles, or square long timbers cut out of Fir, &c. and it is of this sort of Espalier that I shall treat in this place.

Espaliers of fruit-trees are commonly planted to surround the quarters of a kitchen-garden, for which purpose they are of admirable use and beauty; for by laying out the walks of this garden regularly, which are bounded on each side by these hedges, when they are handsomely managed, they have a wonderful effect in sheltering the kitchen-plants in the quarters, and also screening them from the sight of persons in the walks; so that a kitchen-garden well laid out in this manner, and properly managed, will be equal to the finest regular parterre for beauty.

The trees chiefly planted for Espaliers are Apples, Pears, and some Plums; but the two former are mostly used: some plant Espaliers of Apples grafted upon Paradise-stocks; but these being of humble growth, and a short duration, are not so proper for this purpose, unless for very small gardens; therefore I should rather advise the having them upon Crab-stocks, or (if in smaller gardens, where the trees cannot be allowed to grow so high) upon what the gardeners call the Dutch-stock; which will cause them to bear sooner, and prevent their growing too luxuriantly, and these will continue many years in vigour.

In chusing the trees for an Espalier, endeavour as near as possible, to plant the several sorts which are nearly of the same growth in one line, that the Espalier may be the more regular, and of an equal height, which greatly adds to their beauty; for if you plant trees which shoot very unequally in the same line, it will be impossible to make the Espalier regular: besides, the distance of the trees must be in proportion to their growth; for some trees, viz. those of a larger growth, should be planted thirty or thirty-five feet asunder; whereas those of smaller growth, need not be above twenty-five feet distance from each other.

The width of the walks and borders between these Espaliers should (in a large garden) be fourteen or sixteen feet at least; and if the trees are designed to be carried up pretty high, the distance should be greater, that each side may receive the advantage of the sun and air, which is absolutely necessary, if you would have the fruit well tasted. And if your ground is so situated, that you are at full liberty which way to make the Espaliers, I would advise the placing the lines from the east a little inclining to the south, and toward the west a little inclining to the north, that the sun may shine between the rows in the morning and evening when it is low; for in the middle of the day, when the sun is advanced far above the horizon, it will shine over the tops of the Espaliers, and reach the surface of the earth about their roots, which is a matter of more consequence than many people are aware of.

The sorts of Apples proper for Espaliers, are the Golden Pippin, Nonpareil, Renette Grise, Aromatic Pippin, Holland Pippin, French Pippin, Wheeler's Russet, Pile's Russet, with some others. The season for planting, and the method of pruning and training these trees, you will see under the articles of APPLES and PRUNING.

The sorts of Pears proper for an Espalier, are chiefly the summer and autumn fruits, for some of the winter Pears seldom succeed well in an Espalier. These trees, if designed for a strong moist soil, should be upon Quince-stocks; but if for a dry soil upon free-stocks. Their distance of planting must also be regulated by the growth of the trees, which are more unequal in Pears than Apples, and should therefore be more carefully examined before they are planted. As for those Pears upon free-stocks, the distance should never be less than thirty feet for moderate growing trees; but for vigorous shooters, the space of forty feet is little enough; especially if the soil be strong, in which case they should be planted at a greater distance. The particular sorts of Pears I would recommend for an Espalier, are the Jargonelle, Blanquette, Poire fans

ESP

Peau, Summer Boncretien, Hamden's Bergamot, Autumn Bergamot, L'ambrette, Gros Roufflet, Chaumontelle, Beurre du Roy, Le Marquis, Cressane, with some others of less note; always remembering, that those Pears which are of the melting kind, will do better in Espalier than the breaking Pears, which seldom ripen well on an Espalier; as also that many sorts of Pears will ripen well on an Espalier in a warm soil and situation, which require a wall in other places; you should also be careful of the stocks these are grafted on; for if the breaking Pears are grafted upon Quince-stocks, the fruit will be stony, but the melting Pears will be improved by them. As to the method of planting, see the article PEAR; and for pruning and managing, see PRUNING.

I shall now give directions for making the Espalier, to which the trees are to be trained; but this should not be done until the third year after the trees are planted; for while they are young, it will be sufficient to drive a few short stakes into the ground on each side of the trees, in a strait line, to which the branches should be fastened in an horizontal position, as they are produced, in order to train them properly for the Espalier; which stakes may be placed nearer, or at a farther distance, according as the shoots produced may require; and these will be sufficient for the three first years; for should you frame the Espalier the first year the trees are planted, many of the stakes would rot before the Espalier is covered. The cheapest method to make these Espaliers is with Ash-poles, of which you should have two sorts; one of the largest size, which contains thirteen poles in a bundle, and the other size those of half a hundred. The first or largest size poles, should be cut about seven feet and a half long; these are intended for upright stakes, and must be sharpened at the largest end, that they may, with more ease, be driven into the ground; and if their bottoms are burred, or rubbed over with that composition mentioned in the article of COVERINGS, they may be preserved a long time sound; these should be placed at a foot distance from each other in a direct line, and of an equal height, about six feet above ground; then you should nail a row of strait slender poles along upon the tops of the upright stakes, which will keep them exactly even, and continue to cross the stakes with the smaller poles, and also with the tops which were cut off from the larger stakes, at about nine inches distance, row from row, from the top to the bottom of the stakes. These rows of poles should be fastened with wire to the stakes, which if made of Fir, and painted over, will last a long time; and the largest end of the poles should be cut flat, and nailed to the upright stakes, which will secure the Espalier almost as long as the poles will endure; whereas, if your fastening is not strong, the poles will be continually displaced with every strong wind.

When your Espalier is thus framed, you must fasten the branches of the trees thereto either with small Osier-twigs, rope-yarn, or some such binding, observing to train them in a horizontal position, and at equal distances; being careful not to cross any of the branches, nor to lay them in too thick. The distance which should be allowed for the branches of Pears and Apples, must be proportioned according to the size of their fruit; such of them whose fruit is large, as the Summer Boncretien, Monsieur John, and Beurre du Roy Pears, and the Renet Grise, Holland Pippin, French Pippin, and other large Apples, should have their branches six or eight inches distance at least; and to those of lesser growth, four or five inches will be sufficient. But for farther directions, I shall refer to the articles of the several fruits: as also that of PRUNING, where these particulars will be sufficiently explained.

But besides this sort of Espalier made with Ash-poles, there is another sort that is by many people preferred; which is framed with square timbers cut to a proper size, according to the strength thereof, or the expence the owner is willing to go to. These, though they appear more slightly, when well fixed and painted, are not of longer duration than one of the former, provided

E U G

vided it is well made, and the poles are strong which are set upright; nor will they answer the purpose better, though they are vastly more expensive; for the greatest beauty consists in the disposing of the branches of tree; which, especially in summer, when the leaves are on, will entirely hide from the sight the frame of the Espalier; therefore all expence in erecting these is needless, farther than making provision to secure the branches of the trees in a regular order.

Fruit-trees thus planted, and well managed, are much preferable to those trained up in any other figure, upon several accounts; as first, these take up very little room in a garden, so as not to be hurtful to the plants which grow in the quarters; and, secondly, the fruit upon these are better tasted than those which grow upon dwarfs, the sun and air having freer access to every part of the tree; whereby the dampness arising from the ground is sooner dissipated, which is of singular advantage to fruit-trees (as hath been already shewn.) And as the trees against an Espalier are kept low, and the branches being fastened to the Espalier, the fruit will not be blown down so soon by the wind; so that upon the whole, Espaliers must be allowed to be of great use and beauty.

EVER-GREEN THORN. See PYRACANTHA.

EVERLASTING PEA. See LATHYRUS.

EUGENIA. Michel. 108.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into four segments: the flower hath four oblong obtuse petals, twice as large as the empalement. It hath many stamina which are inserted in the empalement, terminated by small summits, and a turbinate germen situated under the flower, supporting a simple style the length of the stamina, crowned by a single stigma. The germen afterward becomes a quadrangular plumb-shaped fruit crowned, having one cell inclosing one smooth roundish nut.

This genus of plants is ranged in the first section of Linnæus's twelfth class, intitled Icosandria Monogynia, the flower having many stamina inserted in the empalement, and one style.

The SPECIES are,

1. EUGENIA (*Malaccensis*) foliis integerrimis, pedunculis racemosis lateralibus. Flor. Zeyl. 187. *Eugenia with entire leaves and branching foot-stalks of flowers. Jambosa domestica. Rump. Amb. 1. p. 121.*
2. EUGENIA (*Jamboo*) foliis integerrimis, pedunculis racemosis terminalibus. Flor. Zeyl. 188. *Eugenia with entire leaves, and branching foot-stalks of flowers terminating the branches. Jambosa sylvestris alba. Rump. Amb. 1. 127.*

There are some other species of this genus which grow naturally in India, but those here mentioned are the only sorts which I have seen in the English gardens. Some plants of the first sort I received from Dr. Heberden with some other plants, which were sent by his brother from the Brasils, where it is cultivated for the table; so that the plants of this kind are common in most parts of the East-Indies.

This rises with a tree-like stem, covered with a brown bark, which, in the countries where it grows naturally, rises from twenty to thirty feet high, sending out many branches, garnished with oblong entire leaves, ending in acute points: these are placed opposite, and when young, are of a bright purple colour; but as they grow older, become of a light green. The flowers are produced on the side of the branches, each foot-stalk branching into three or four others, each supporting one flower. These are succeeded by irregular-shaped succulent fruit, inclosing one nut.

The second sort rises to the same height as the first, but the leaves are longer and narrower. The flowers do, for the most part, terminate the branches, though there are some which come on their sides. The fruit of this is smaller, rounder, and not so much esteemed as those of the first.

These plants are preserved in the gardens of the cu-

E U O

rious for the sake of variety, though there is little hopes of their producing fruit in England. They may be propagated by their stones, if they can be obtained fresh from the countries of their natural growth. The stones should be planted in small pots filled with light earth, and plunged into a hot-bed, observing to keep the earth moist but not wet; in about six weeks the plants will appear; and when grown four inches high, they should be carefully separated, planting each into a small pot, plunging them into the hot-bed again, being careful to shade them till they have taken new root; after which, they should be treated in the same way as other tender plants from the same country, always plunging them into the tan-bed in the stove; and in winter be sparing in water to them, for much wet will kill them.

EUONYMUS. Lin. Gen. Plant. 240. Tourn. Inst. R. H. 617. tab. 388. [Εὐώνυμος, of *eu*, good, and *onyma*, a name; so called by way of antiphrasis, because it is hurtful to animals.] The Spindle-tree, or Prickwood; in French, *Fusain*.

The CHARACTERS are,

It hath a short empalement to the flower of one leaf, which is divided into four or five segments. The flower hath four or five oval petals, which spread open. It hath five short stamina, which are joined at their base to the germen, terminated by twin summits. In the center is situated a large oval germen, supporting a short style, crowned by an obtuse stigma. The germen afterward becomes a succulent four-cornered coloured capsule, having as many cells as angles, each containing one oval seed.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. EUONYMUS (*Vulgaris*) foliis lanceolatis, floribus tetrandriis, fructu tetragono. *Spindle-tree with spear-shaped leaves, flowers having four stamina, and quadrangular fruit. Euonymus vulgaris, granis rubentibus. C. B. P. 428. The common Spindle-tree.*
2. EUONYMUS (*Latifolius*) foliis ovato-lanceolatis, floribus pentandris, fructu pentagono, pedunculis longissimis. *Spindle-tree with oval spear-shaped leaves, flowers having five stamina, a five-cornered fruit, and very long foot-stalks. Euonymus latifolius. C. B. P. 428. Broad-leaved Spindle-tree.*
3. EUONYMUS (*Americanus*) floribus omnibus quinquefidis. Lin. Sp. Plant. 197. *Spindle-tree whose flowers are all divided into five points. Euonymus Virginianus, pyracanthæ foliis, sempervirens, capsulâ verrucarum instar asperatâ rubente. Pluk. Phyt. 115. f. 5. Virginian evergreen Spindle-tree with rough, warted, red seed-vessels.*
4. EUONYMUS (*Pinnatis*) foliis pinnatis, fructu racemoso trigono. *Spindle-tree with winged leaves, and three-cornered fruit growing in bunches. Euonymus caudice non ramoso, folio alato, fructu rotundo tripyreno. Sloan. Cat. Jam. 171. Spindle-tree with an unbranching stalk, a winged leaf, and a round fruit having three seeds. The first sort grows naturally in England. It is very common in hedges, and is sometimes found growing in woods. This, when growing in hedges, is seldom seen of any considerable size, but rather appears like a shrub; but if planted single, and trained up like other trees, will have a strong woody stem, and rise more than twenty feet high, dividing into many branches, garnished with spear-shaped leaves about three inches long, and one inch and a quarter broad in the middle, gradually diminishing to both ends; they are entire, of a deep green colour, and are placed opposite. The flowers come out in small bunches from the side of the stalks, standing upon slender foot-stalks; they are composed of four whitish petals, which are expanded in form of a cross. The empalement is divided into four parts. The flowers have four stamina, and the fruit is four-cornered, and opens into four cells. This tree flowers the latter part of May and the beginning of June, and the fruit ripens in October, at which time the seed-vessels spread open*

E U O

and expose the seeds, which are of a beautiful red colour; so that when the branches are well stored with them, the trees make a good appearance at that season, when growing among other sorts. The wood of this tree is used by the musical instrument-makers for tooting of organs and virginal keys; the branches are cut into tooth-pickers, and for making of skewers; and spindles are made of the wood, from whence the tree was titled Spindle-tree; but in some counties it is called Dogwood.

The second sort grows naturally in Austria and Hungary; this was very seldom seen in England till of late years, since I procured it from France, and from the seeds of those plants great numbers have been since raised, so it is now pretty common in several of the nurseries near London; this rises with a stronger stem than the first, and grows to a larger size. The leaves are oval and spear-shaped, about four inches long, and two inches broad in the middle, of a light green colour, and entire; they are placed opposite on the branches, with short foot-stalks. The flowers come out from the side of the branches, upon very slender foot-stalks, which are two inches and a half long; these branch out into a loose bunch, so that the flowers stand upon separate foot-stalks. The flowers have five petals, which at first are white, but afterward change to a purple colour; the empalement of the flower is divided into five parts. It hath five stamina, and the fruit is frequently five-cornered; the fruit is much larger than that of the common sort, and the foot-stalks being weak, the fruit always hang down. Dr. Linnæus has supposed these to be but one species, and has taken the characters of this genus from the second sort, whose flowers have five stamina and five petals, and the fruit five corners; but all those of the common sort which I have examined have but four, and these differences are permanent in those plants which rise from seeds; for I have raised many of both sorts from seeds, but have never found either of them alter.

The third sort grows naturally in Virginia, Carolina, and other parts of North America; this rises with a shrubby stalk to the height of eight or ten feet, dividing into many branches, which come out opposite from the joints of the stem; these are garnished with spear-shaped leaves, which are two inches long, and about three quarters of an inch broad in the middle, ending in acute points; they are placed opposite, and continue green all the year. The flowers are produced at the end of the branches, and also from the sides, in small clusters, which are succeeded by round capsules, which are closely armed by rough protuberances. This flowers in July, but seldom produces ripe fruit in England.

As this is an evergreen shrub, so it merits a place in every curious garden, and particularly in all plantations of evergreen trees and shrubs; there is a variety of this with variegated leaves, which is preserved in the nursery-gardens.

The fourth sort grows naturally in Jamaica, and some of the other islands in the West-Indies; this rises with an upright woody stalk, to the height of ten or twelve feet; at the top it divides into two or three short branches, which are garnished by winged leaves, composed of six or seven pair of small leaves (or lobes) about two inches long, and one inch broad; these leaves come out without order, standing upon long foot-stalks. The flowers come out in clusters from the side of the branches, toward their end; these are succeeded by roundish capsules, having a thick brown cover, which open in three cells, each containing a single hard seed.

The two first sorts may be propagated either by seeds, or layers; if by seeds, they should be sown in autumn, soon after they are ripe; then the plants will come up the spring following; but if the seeds are not sown till spring, the plants will not appear till the following spring, whereby a whole year is lost. The seeds should be sown upon a shady border, where they will succeed better than when they are more exposed to the sun.

E U P

When the plants come up, they will require no other care but to keep them clean from weeds till the following autumn, when, as soon as their leaves decay, the plants should be taken up and transplanted into a nursery, in rows two feet distant, and the plants one foot asunder in the rows; in this place they may remain two years, and then they may be removed to the places where they are to remain.

When these are propagated by layers, the young shoots should be laid down in autumn; and if the joint which is laid deepest in the ground is slit, as is practised for Carnations, it will cause them to put out roots much sooner than they otherwise would do; these layers will be sufficiently rooted in one year to bear transplanting, when they should be taken from the old plants, and treated in the same way as the seedlings. The cuttings of these sorts, planted in a shady border, will take root, but they should be planted in autumn, as soon as their leaves begin to fall; they should be the shoots of the same year, with a knot of the former year at bottom.

The third sort, which grows naturally in North America, is so hardy as rarely to suffer by cold in England, provided it is not planted in places very much exposed. This may be propagated by laying down the young branches in the autumn, observing to tongue them in the same manner as is practised in laying of Carnations: these will have made good roots in one year, when they may be cut from the old plants, and planted in a nursery for two years to get strength; after which, they should be planted where they are designed to remain.

The fourth sort is a native of warmer countries, so cannot be preserved in England, unless it is placed in a stove in winter: this is generally propagated by seeds, which must be sown in pots, and plunged into a hot-bed; and when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into the hot-bed again, being careful to shade them until they have taken new root; after which they must be treated in the same way as other tender plants of the same countries. This sort may also be propagated by cuttings during any of the summer months.

EUPATORIO PHALACRON. See VERBESINA.

EUPATORIUM. Lin. Gen. Plant. 842. Tourn. Inst. R. H. 455. tab. 259. [Εὐπατόριον, of king Eupator, who first brought this plant into use.] Hemp Agrimony; in French, *Eupatoire*.

The CHARACTERS are,

It hath a compound flower, composed of several hermaphrodite florets, which are funnel-shaped, cut into five parts at the brim, which spread open; these are included in one common scaly empalement, whose scales are narrow, erect, and unequal. The florets have each five short hairy stamina, terminated by cylindrical summits. In the bottom is situated a small germen, supporting a long slender style, which is bifid, crowned by a narrow stigma. The germen afterward becomes an oblong seed, crowned with down, sitting in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, which includes those plants with compound flowers, which have only hermaphrodite fruitful flowers.

The SPECIES are,

1. EUPATORIUM (*Cannabinum*) foliis digitatis. Hort. Cliff. 396. *Eupatorium with fingered leaves.* Eupatorium cannabinum. C. B. P. 320. *Common Hemp Agrimony.*
2. EUPATORIUM (*Maculatum*) foliis lanceolato-ovatis, serratis, petiolatis, caule erecto. Hort. Cliff. 396. *Eupatorium with spear-shaped oval leaves which are sawed, having foot-stalks, and an upright stalk.* Eupatorium Novæ Angliæ, urticæ foliis, floribus purpurascens, maculato caule. H. L. *New England Hemp Agrimony with Nettle leaves, purplish flowers, and spotted stalks.*
3. EUPATORIUM (*Purpureum*) foliis subverticillatis, lanceolatis serratis petiolatis rugosis. Lin. Sp. Plant. 838. *Eupatorium with leaves placed in whorls, which are spear-*

- spear-shaped, sawed, rough, and have foot-stalks. *Eupatorium folio oblongo rugoso, caule purpurascete.* Tourn. Inst. 456. *Canada Hemp Agrimony with a long rough leaf, and purplish stalk.*
4. *EUPATORIUM (Scandens)* caule volubili, foliis cordatis dentatis acutis. Hort. Cliff. 396. *Eupatorium with a twining stalk and heart-shaped leaves, which are sharply indented. Eupatorium Americanum scandens, hastato magis acuminato folio.* Vaill. Mem. 1719. *Climbing American Hemp Agrimony, with a spear-like sharp-pointed leaf.*
 5. *EUPATORIUM (Rotundifolium)* foliis sessilibus distinctis subrotundo-cordatis. Lin. Sp. Plant. 837. *Eupatorium with roundish heart-shaped leaves sitting close to the stalks, and are distinct. Eupatorium Americanum, foliis rotundioribus absque pediculis.* Vaill. Mem. 1719. *American Hemp Agrimony with round leaves, having no foot-stalks.*
 6. *EUPATORIUM (Fruticosum)* foliis oblongo-cordatis, floribus paniculatis, caule fruticoso scandente. *Eupatorium with oblong heart-shaped leaves, paniculated flowers, and a climbing shrubby stalk. Eupatorium scandens, foliis subrotundis lucidis, floribus spicatis albis.* Houst. MSS. *Climbing Hemp Agrimony with roundish shining leaves, and white flowers growing in spikes.*
 7. *EUPATORIUM (Odoratum)* foliis ovatis, obtusè ferratis petiolatis trinerviis, calycibus simplicibus. Lin. Sp. Plant. 839. *Eupatorium with oval, obtuse, sawed, three-veined leaves, having foot-stalks, and single empalements to the flowers. Eupatorium Americanum, teucris folio, flore niveo.* Vaill. Mem. Acad. Scien. *American Hemp Agrimony with a Tree Germander leaf, and a white flower.*
 8. *EUPATORIUM (Perfoliatum)* foliis connatis tomentosis. Hort. Cliff. 396. *Eupatorium with woolly leaves joined at their base. Eupatorium Virginianum, salviae foliis longissimis acuminatis, perfoliatum.* Pluk. Alm. *Virginian perfoliate Hemp Agrimony, with long Sage-like leaves closely surrounding the stalk.*
 9. *EUPATORIUM (Betonicefolium)* foliis oblongis, obtusis, crenatis, glabris, calycibus simplicibus. *Eupatorium with oblong, obtuse, smooth, crenated leaves, and single empalements to the flowers. Eupatorium betonicæ folio glabro & carnofo, flore cœruleo.* Houst. MSS. *Hemp Agrimony with a fleshy smooth Betony leaf, and a blue flower.*
 10. *EUPATORIUM (Morifolium)* foliis cordatis serratis caule erecto arboreo. *Eupatorium with heart-shaped sawed leaves, and an upright tree-like stalk. Eupatorium Americanum arborecens, mori folio, floribus albicantibus.* Houst. MSS. *Tree-like American Hemp Agrimony, with a Mulberry leaf and white flowers.*
 11. *EUPATORIUM (Punctatum)* foliis ovatis petiolatis integris, caule fruticoso ramoso, calycibus simplicibus. *Eupatorium with oval entire leaves having foot-stalks, a branching shrubby stalk, and single empalements to the flowers. Eupatorium Americanum frutescens, balsaminæ lutæ foliis, nigris maculis punctatis.* Houst. MSS. *American shrubby Hemp Agrimony, with yellow Balsamine leaves spotted with black.*
 12. *EUPATORIUM (Hyssofolium)* foliis lanceolato-linearibus trinerviis sub integerrimis. Lin. Sp. Plant. 836. *Eupatorium with narrow, spear-shaped, entire leaves, having three nerves. Eupatorium Virginianum, folio angusto floribus albis.* Hort. Elth. 141. tab. 115. f. 140. *Virginia Hemp Agrimony, with a narrow leaf, and white flowers.*
 13. *EUPATORIUM (Ramosum)* foliis lanceolato-linearibus acutis, supernè serratis caule ramoso. *Hemp Agrimony with narrow, spear-shaped, pointed leaves, sawed on their upper part, and a branching stalk.*
 14. *EUPATORIUM (Conyzoides)* foliis cordatis acutis, dentatis, trinerviis, caule fruticoso ramoso. *Eupatorium with pointed, heart-shaped, sawed leaves, having three veins, and a branching shrubby stalk. Conyza fruticosa, folio hastato, flore pallide purpureo.* Sloan. Cat. Jam. 124. *Shrubby Fleabane with a spear-shaped leaf, and a pale purple flower.*
 15. *EUPATORIUM (Paniculatum)* foliis cordatis rugosis crenatis, caule paniculato. *Eupatorium with rough, heart-shaped, crenated leaves, and a paniculated stalk.*

- Conyza Salviae foliis conjugatis, floribus spicatis rubentibus.* Houst. MSS. *Fleabane with Sage leaves placed opposite, and red flowers growing in spikes.*
16. *EUPATORIUM (Houstonia)* foliis cordatis acuminatis, caule volubili, floribus spicatis racemosis. *Eupatorium with heart-shaped pointed leaves, a twining stalk, and branching spiked flowers. Eupatorium Americanum, scandens, folio hastato glabro, floribus spicatis.* Houst. MSS. *Climbing American Hemp Agrimony with a smooth spear-shaped leaf, and spiked flowers.*
 17. *EUPATORIUM (Trifoliatum)* foliis ternis. Flor. Virg. 119. Lin. Sp. Plant 838. *Hemp Agrimony with trifoliate leaves.*
 18. *EUPATORIUM (Alissimum)* foliis lanceolatis nervosis, inferioribus extimo sub serratis, caule fruticoso. Hort. Upsal. 152. *Eupatorium with nervous spear-shaped leaves, whose lower leaves are sawed on their edges, and stand in whorls round the stalks. Eupatorium folio oblongo, rugoso, ampliori, caule virescente.* Tourn. Inst. R. H. 456. *Hemp Agrimony with a large, oblong, rough leaf, and a green stalk.*
 19. *EUPATORIUM (Cælestinum)* foliis cordato-ovatis, obtusè ferratis petiolatis, calycibus multifloris. Lin. Sp. Plant. 838. *Eupatorium with heart-shaped oval leaves obtusely sawed, having foot-stalks, and many flowers to the empalements. Eupatorium scorodoniæ folio, flore cœruleo.* Hort. Elth. 140. tab. 114. *Hemp Agrimony with a Wood Sage leaf, and a blue flower.*

The last grows naturally in Carolina, from whence the late Dr. Dale sent me the seeds; these plants flowered very finely the year after they were raised, but never have flowered since, for the roots creep greatly in the ground, but never send up any stalks.

The first sort grows naturally by the side of rivers and ditches in most parts of England, and is the only species of this genus, which is known to grow naturally in Europe; this is esteemed as a very good vulnerary herb, so stands in the list of medicinal plants. It is seldom admitted into gardens, because, wherever it is suffered to seed, the ground will be well stored with the plants to a great distance.

The second sort grows naturally in several parts of North America, from whence it has been introduced to the gardens in Europe; this hath a perennial root, but an annual stalk, which rises about two feet and a half high; it is purple, and has many dark spots upon it. The leaves are rough, oval and spear-shaped, having foot-stalks; they are placed by threes round the stalk toward the bottom, but upward by pairs opposite at each joint. The stalks are terminated by clusters of purple flowers, growing in a sort of corymbus; these come out in July and August, and in warm seasons will ripen its seeds in autumn.

The third sort grows naturally in North America; this rises with an upright stalk near four feet high, garnished with long, narrow, spear-shaped leaves at each joint; these are deeply sawed on their edges, and the midrib is oblique to the foot-stalk; they are placed by fours round the stalk in whorls, and are of a dark green colour. The stalks are terminated by bunches of purple flowers like the last, which appear at the same time. This hath a perennial root and an annual stalk.

The fourth sort grows naturally in Virginia and Carolina; this hath a perennial root, which sends out many twining stalks in the spring; these twist about any neighbouring support, and rise to the height of five or six feet, garnished at each joint with two heart-shaped leaves, which are indented on their edges, and terminate in acute points; at each joint there are two small side branches come out, which are terminated by clusters of white flowers, so that the stalks seem covered with them most part of their length; but as these come pretty late in the season, so unless the summers prove warm, the plants do not flower well in England.

There is another of these plants with purple flowers, standing upon longer foot-stalks, which was sent me from Campeachy; but the stalks and leaves are very like

like those of this sort, so that I doubt whether it be a distinct species.

The fifth sort grows naturally in New England and Virginia, from both of these counties I have received the seeds; this hath a perennial root and an annual stalk; it rises with upright stalks about a foot high; these have their joints pretty near each other, where they are garnished with roundish heart-shaped leaves, sitting close to the stalks; they are sawed on their edges, and are of a light green colour. The flowers are produced in small loose panicles at the top of the stalks; they are white, and have two small green leaves immediately under the flowers. These flowers appear the latter end of June, but the seeds seldom ripen in England.

The sixth sort grows naturally at La Vera Cruz in America, from whence the late Dr. Houston sent me the seeds; this hath a shrubby climbing stalk, which rises to the height of ten or twelve feet, fastening itself to any neighbouring prop for support, and is garnished with heart-shaped leaves, placed opposite; they are about three inches long, and one and a half broad, of a lucid green; the flowers come out in long branching panicles, which proceed from the side of the stalks, and are terminated by a branching panicle of white flowers. This sort is tender, so will not live in this country without artificial heat.

The seventh sort rises with upright stalks three feet high, garnished with oval leaves at each joint, which are placed opposite; they have very short foot-stalks, and are sawed on their edges; from the sides of the stalks, at every joint, is produced two slender branches, which stand erect; these, and the principal stalks also, are terminated by clusters of white flowers; they appear in August and September, and the stalks decay in winter, but the root is perennial. This grows naturally in Pennsylvania, and other parts of America.

The eighth sort grows naturally in Virginia and Philadelphia; this hath a perennial root and an annual stalk. The stalks rise from two to three feet high; they are hairy, and garnished with rough leaves at each joint, which are from three to four inches long, and about an inch broad at their base, gradually lessening to a very acute point; the two leaves are joined at their base, so the stalks seem to grow through them; they are of a dark green, and are covered with short hairs. The upper part of the stalk divides into many slender foot-stalks, each sustaining a close cluster of white flowers. These come out in July, and in warm seasons the seeds will sometimes ripen in England.

The ninth sort grows naturally at La Vera Cruz, from whence the late Dr. Houston sent me the seeds; this rises with an upright stalk near two feet high, garnished toward the bottom with oblong obtuse leaves, which are of a thick substance, and crenated on their edges; the upper part of the stalk is naked to the top, where the flowers come out in a thick panicle; they are blue, and have single empalements. This flowers late in autumn, but never ripens seeds here; the root is biennial, and perishes soon after it has flowered.

The tenth sort was sent me by the late Dr. Houston from La Vera Cruz, where he found it growing naturally; this hath a thick woody stalk, which rises twelve or fourteen feet high, sending out many branches, which are channelled, and covered with a brown bark, garnished with regular heart-shaped leaves as large as those of the Mulberry-tree; they are of a light green colour, and sawed on their edges, placed opposite upon foot-stalks, near two inches long; the upper part of the branches are terminated by four or five pair of foot-stalks, which come out opposite from the joints, and the top is terminated by an odd one; these sustain branching panicles of white flowers, which together form a long loose pyramidal thyrse, and make a fine appearance, for there are no leaves intermixed with the flowers, but so far as the spike reaches the stalks are naked. This sort has flowered in the Chelsea garden, but did not produce seeds.

The eleventh sort grows naturally at La Vera Cruz, from whence the late Dr. Houston sent it me; this rises with many shrubby stalks near five feet high, which divide into many slender branches, whose joints are three or four inches asunder; at each of these come out two oval leaves about three quarters of an inch long, and half an inch broad, standing upon long slender foot-stalks; they have several black spots on their surface. The branches come out horizontal, and are terminated by small bunches of white flowers, whose empalements are single, and composed of seven narrow spear-shaped leaves, which are divided to the bottom.

The twelfth sort rises with an upright round stalk to the height of three feet, sending out several branches toward the top, which come out regularly by pairs; they are garnished with leaves, placed by pairs; these are two inches and a half long, and about one third of an inch broad, having three longitudinal veins; they are of a light green colour, and entire. The flowers stand upon long foot-stalks at the end of the branches, some sustaining one, some two, and others three or four flowers; they are white, and appear late in autumn. This grows naturally in Carolina.

The thirteenth sort grows naturally in Maryland; this hath a perennial root and an annual stalk, which rises three feet high, dividing upward into many branches, which are closely garnished with narrow spear-shaped leaves, which are from two to three inches long, and a quarter of an inch broad, of a deep green, sitting close to the branches; they have three longitudinal veins, and their upper part sharply sawed on their edges, ending in acute points. The branches are terminated by roundish clusters of white flowers, which appear in August, and continue till October; and in warm seasons they are succeeded by seeds, which ripen here.

The fourteenth sort grows naturally in Jamaica, and in most of the other islands in the West-Indies; this rises with shrubby stalks about six or seven feet high, dividing into many branches, which are garnished with heart-shaped leaves, ending in acute points, indented on their edges, having three longitudinal veins; the upper part of the branches are terminated by slender foot-stalks, each sustaining a small cluster of white flowers, included in oblong scaly empalements of a silvery colour.

The fifteenth sort was sent me from La Vera Cruz by the late Dr. Houston; this rises with an upright branching stalk three feet high, sending out two side branches from every joint, almost the whole length, which are terminated by loose spikes of red flowers, as is also the principal stalk. The leaves are heart-shaped, rough, and are crenated on their edges, sitting close to the stalks; they are of a light green, and a little hoary.

The sixteenth sort was sent me from Jamaica by the late Dr. Houston; this hath slender twining stalks, which fasten themselves to any neighbouring support, and rise eight or ten feet high, sending out small branches opposite, at most of the upper joints. The leaves on the lower part of the stalk are heart-shaped, ending in acute points; the upper leaves are almost triangular, they are smooth, and of a lucid green; the upper part of the stalks have long branching spikes of white flowers, which are small, and sit close to the foot-stalks.

The seventeenth sort grows naturally in Pennsylvania; this hath a perennial root, from which arise several upright stalks, which grow to the height of seven or eight feet, in a moist soil, or where they are supplied with water in dry weather, and are garnished with oval, rough, spear-shaped leaves, which are a little sawed on their edges; they are placed in whorls round the stalks, sometimes seven, at other places four or five of these stand at each joint; they are about three inches long, and two inches broad. The stalks are terminated by a loose corymbus of purple flowers, which appear in August and continue till October, but are not succeeded by seeds in England.

The

E U P

The eighteenth sort rises with a single, upright, green stalk, about four feet high, garnished at each joint by four spear-shaped leaves, placed in whorls round the stalks; they are six inches long, and two inches broad in the middle, lessening to both ends, terminating in acute points; they are rough, sawed on their edges, and stand on short foot-stalks; the stalk is terminated by a close corymbus of purple flowers, which appear in July, and continue till September. The root is perennial, but the stalks decay every winter; it grows naturally in North America.

The nineteenth sort grows naturally in Carolina; this hath a creeping root, which spreads and multiplies very fast. The stalks rise about two feet high; they are garnished with oval heart-shaped leaves, which have foot-stalks, and are sawed on their edges. The flowers are produced at the top of the stalks in a sort of corymbus; they are of a fine blue colour, but the roots spread so much as to cause barrenness of flowers after the first year.

All these sorts may be propagated by seeds; several of them ripen their seeds in England; these should be sown in autumn as soon as they are ripe, for then the plants will come up the following spring; but if they are kept out of the ground till spring, the plants will not come up till the year after; and those seeds which are procured from America should be sown as soon as they arrive, for though they may not grow the first year, yet there will be a greater certainty of their succeeding, than when they are kept longer out of the ground.

The second, third, fifth, seventh, eighth, twelfth, thirteenth, seventeenth, eighteenth, and nineteenth sorts are hardy plants, so the seeds of these may be sown in the full ground, but there must be care taken in the sowing to keep the sorts separate; for as the seeds of these plants have a light down adhering to them, they are easily displaced by the least wind; so that the best way will be to sow them in drills, but these should be but shallow, for if the seeds are buried too deep they will not grow. The bed in which these are sown should not be too much exposed to the sun, but rather have an east aspect, where the morning sun only reaches it; but where it is more exposed, it should be shaded with mats in the heat of the day, and the ground should be kept pretty moist; for as these plants generally grow in moist shady situations in their native countries, they will succeed better when they have a soil and situation somewhat like that; though as we want their heat in summer, the plants will thrive here when exposed to the sun, provided they have a moist soil, or are supplied with water in dry weather.

When the young plants come up, they must be kept clean from weeds; and where they are too close, some of them should be drawn out, to give room for the others to grow; and if these are wanted, they may be planted in another bed, where, if they are shaded and watered, they will soon take root; after which they will require no farther care but to keep them clean from weeds till the following autumn, when they may be transplanted to the places where they are to remain. As the roots of these plants spread out to a considerable distance, they should not be allowed less than three feet from any other plants, and some of the largest growing should be allowed four feet. If the soil in which they are planted is a soft gentle loam, they will thrive much better, and flower stronger than in light dry ground; in which, if they are not duly watered in dry summers, their leaves will shrink, and their stalks will not grow to half their usual height.

All these sorts have perennial roots, by which they may be propagated; for as some of them do not perfect their seeds in England, so that is the only way of increasing the plants here; some of the sorts have creeping roots, sending out offsets in great plenty, so these are easily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing of which there should be care

E U P

taken not to cut or injure the old plants too much, which would cause them to flower weak the following year. The best time to remove these plants is in autumn, as soon as they have done growing, that they may get fresh roots before the frost comes on; but if that should happen soon after their removal, if the surface of the ground is covered with tan, or dried leaves, to keep out the frost, it will effectually secure them; and if this is done to the old plants in very severe winters, it will always preserve them; but the nineteenth sort is the only one which I have known killed by frost: however, it may not be amiss to practise this on the young seedling plants, which have not so good roots, nor are so well established in the ground; the future culture will be only to dig the ground about them every spring, and keep them clean. The fourth sort sends out many weak twining stalks, which require support; so there should be some stakes fixed down by their roots in the spring when they begin to shoot, to which the young stalks should be led and fastened, and afterward they will naturally twine round them and rise four or five feet high if they are supplied with water, and in warm seasons they will produce plenty of white flowers in August. This sort is sometimes killed in very severe winters, if they are not covered; but if, when the stalks decay in the autumn, the ground about them is covered with some old tanners bark, it will effectually secure the roots. This sort multiplies very fast by its creeping roots, which may be parted every other year.

The sixth and sixteenth sorts have twining slender stalks, which require to be supported in the like manner; but these are natives of warm countries, so they will not thrive in England, unless they are placed in a warm stove; therefore they should be planted in pots and plunged into the tan-bed in the stove, where, if they are supplied with wet in hot weather, they will thrive and produce flowers. The sixth sort hath shrubby stalks, and does not propagate by the root, so there should be layers made of the young branches, which will put out roots if they are properly supplied with water; but the sixteenth sort may be propagated by parting the roots, in the same manner as the fourth sort.

The ninth and fifteenth sorts have perennial roots, but their stalks decay every winter. These are tender plants, so should be planted in pots, and kept constantly plunged in the tan-bed in the stove, where they will thrive and flower. These may be propagated by cutting off some of their young shoots about the middle of June, when they have strength, and planted into pots filled with light earth, and plunged into a moderate hot-bed, where, if they are shaded from the sun, and gently watered as they may require it, they will put out roots in six weeks, and may then be transplanted into separate pots, and treated as the old plants.

The tenth, eleventh, and fourteenth sorts have shrubby stalks, which are perennial. These are natives of warm countries, so will not thrive in England out of a stove; therefore they should be planted in pots and kept plunged in the tan-bed of the stove, and treated as the former sorts. These will sometimes take root from cuttings, but not very freely, so that the best way is from seeds when they can be procured. When the seeds of these tender sorts can be had from their native countries, the plants raised that way are much preferable to those which are obtained by any other method, and will flower much stronger, therefore should be preferred; but as these seeds seldom grow the first year, few persons have patience enough to wait for the plants coming up. When any of these seeds are brought over, they should be sown as soon as they arrive in pots, that they may be removed at any time; the pots should be plunged into a moderate hot-bed, and the earth kept tolerably moist; the glasses should also be shaded in the heat of the day, to prevent the earth from drying; in this hot-bed the pots may remain till autumn, when, if the plants are not up, they should be plunged between

the plants in the bark-stove, and in the spring removed to a gentle hot-bed, which will bring up the plants soon after. When these are fit to remove they should be planted in separate small pots, and plunged into the hot-bed again, shading them from the sun till they have taken new root; then they should have a large share of free air admitted to them in warm weather, and frequently refreshed with water.

In the winter these plants should be more sparingly watered, especially those sorts whose stalks decay; and in the summer they should have a large share of free air admitted to them, with which management they will thrive and flower.

EUPHORBIA. Lin. Gen. Plant. 536. Euphorbium. Boer. Ind. alt. 1. 258. Tithymalus. Tourn. Inst. R. H. 85. tab. 18. The Burning Thorny Plant.

This plant was named Euphorbia by King Juba, the father of Ptolemy, who governed both the Mauritania; whose physician was named Euphorbus, and his brother Antonius Musa is said to have healed Augustus with this plant.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is swelling, rough, and divided into five parts at the brim. The flower hath four or five thick truncated petals, and twelve or more stamina which are inserted in the receptacle; they are longer than the petals, and are terminated by globular summits. In the center is situated a three-cornered germen, supporting three bifid styles, crowned by obtuse stigmas. The germen afterward becomes a roundish capsule with three cells, each containing one roundish seed.

This genus of plants is ranged in the third section of Linnæus's eleventh class, which includes the plants whose flowers have twelve stamina and three styles. To this genus he has added the Tithymalus and Tithymaloides of Tournefort and others. The difference between the Euphorbium and Tithymalus, consists more in their outward form, than in the characters of either flower or fruit, so may be properly enough joined together; but the flower of Tithymaloides being very different in its form, should be separated from them, therefore I shall place them under the title of Tithymalus; and as the number of Tithymali is very great, many of which are common weeds, I shall select only the more rare or useful kinds to enumerate here.

The SPECIES are,

1. **EUPHORBIA** (*Antiquorum*) aculeata triangularis subnuda articulata, ramis patentibus. Lin. Hort. Cliff. 196. *Euphorbia with triangular jointed stalks which are naked, and have spines and spreading branches. Euphorbium verum antiquorum.* Hort. Amst. 1. p. 23. *Prickly triangular-pointed Euphorbia, with spreading branches, commonly called the true Euphorbium of the ancients.*
2. **EUPHORBIA** (*Canariensis*) aculeata nuda subquadrangularis, aculeis geminatis. Hort. Cliff. 196. *Euphorbia with naked stalks, which have four angles and double spines. Euphorbium tetragonum & pentagonum spinosum Canarium.* Boerh. Ind. alt. 1. 258. *Canary Euphorbium with four or five angles which have spines.*
3. **EUPHORBIA** (*Trigonum*) aculeata nuda triangularis articulata, ramis erectis. *Thorny-jointed triangular Euphorbia with upright naked branches. Euphorbium trigonum & tetragonum spinosum, ramis compressis.* D'Isnard. Act. Par. 1720. *Prickly Euphorbium having three and four angles with compressed branches.*
4. **EUPHORBIA** (*Officinarum*) aculeata nuda multangularis, aculeis geminatis. Lin. Hort. Cliff. 196. *Thorny Euphorbia having many angles and spines growing by pairs. Euphorbium cerei effigie caulibus crassioribus, spinis validioribus armatum.* Hort. Amst. 1. p. 21. *Torch-shaped Euphorbium, with thick stalks armed with strong spines.*
5. **EUPHORBIA** (*Neriifolia*) aculeata seminuda, angulis oblique tuberculatis. Lin. Hort. Cliff. 196. *Thorny half-naked Euphorbia with oblique tubercular angles, commonly called the Oleander-leaved Euphorbium. Euphorbium angulosum, foliis nerii latioribus.* Boerh. Ind.

alt. 1. 258. *Angular Euphorbium, with broad Oleander leaves.*

6. **EUPHORBIA** (*Heptagona*) aculeata nuda, septem-angularis, spinis solitariis subulatis floriferis. Lin. Hort. Cliff. 196. *Naked septangular thorny Euphorbia, with single awl-shaped spines, producing flowers at their extremities. Euphorbium heptagonum, spinis longissimis in apice fructiferis.* Boerh. Ind. alt. 1. 258. *Euphorbium with seven angles and very long spines, bearing fruit at their tops.*
7. **EUPHORBIA** (*Caput Medusæ*) inermis tuberculis imbricatis, foliolo lineari instructis. Lin. Hort. Cliff. 197. *Euphorbia without thorns, closely covered with tubercles lying over each other like tiles, and narrow leaves, commonly called Medusa's Head. Euphorbium Afrum, caule crasso squamoso, ramis in capitis Medusæ speciem cincto.* Boerh. Ind. alt. 258. *African Euphorbium with a thick scaly stalk, and branches disposed like Medusa's head.*
8. **EUPHORBIA** (*Mamillaris*) aculeata nuda, angulis tuberosis, spinis interstinctis. Lin. Sp. Plant. 451. *Naked prickly Euphorbia, with tuberos angles having spines growing between them. Euphorbium polygonum aculeis longioribus ex tuberculorum internodiis prodeuntibus.* D'Isnard. Act. Par. 1720. *Euphorbium with many angles, and long spines growing out from between the knots.*
9. **EUPHORBIA** (*Cerciformis*) aculeata nuda, multangularis, spinis solitariis subulatis. Prod. Leyd. 195. *Naked thorny Euphorbia with many angles, and single awl-shaped spines. Euphorbium cerei effigie, caulibus gracilioribus.* Boerh. Ind. alt. 1. 258. *Euphorbium with the appearance of Torch Thistle, and a slender stalk.*
10. **EUPHORBIA** (*Fruetus Pini*) inermis imbricata tuberculis foliolo lineari instructis. Hort. Cliff. 197. *Imbricated Euphorbia without spines, having tubercles furnished with very narrow leaves. Euphorbium Afrum, facie fructus pini.* Boerh. Ind. alt. 1. 258. *African Euphorbium with the appearance of Pine fruit, commonly called Little Medusa's Head.*
11. **EUPHORBIA** (*Patula*) inermis, ramis patulis simplicibus teretibus, foliolis linearibus instructis. *Euphorbia without spines, having single spreading branches which are taper, terminated with very narrow leaves.*
12. **EUPHORBIA** (*Procumbens*) inermis ramis teretibus procumbentibus tuberculis quadrangulis. *Euphorbia without spines, having trailing branches with quadrangular tubercles.*
13. **EUPHORBIA** (*Inermis*) inermis, ramis plurimis procumbentibus, squamosis, foliolis deciduis. *Euphorbia without spines, having many trailing branches which are scaly, and deciduous leaves.*
14. **EUPHORBIA** (*Tiruaculii*) inermis fruticosa subnuda filiformis erecta, ramis patulis determinatè confertis. Lin. Hort. Cliff. 197. *Shrubby erect Euphorbia without spines, and slender spreading branches terminating in clusters, commonly called Indian-tree Spurge. Tithymalus Indicus frutescens.* Hort. Amst. 1. p. 27. *Indian shrubby Spurge.*
15. **EUPHORBIA** (*Viminalis*) inermis fruticosa nuda filiformis volubilis, cicatricibus oppositis. Hort. Cliff. 197. *Shrubby naked Euphorbia without spines, and slender twining branches, commonly called Indian Climbing Spurge. Tithymalus Indicus vimineus penitus aphyllus. Indian Spurge with slender branches, entirely without leaves.*
16. **EUPHORBIA** (*Mauritanica*) inermis fruticosa feminuda filiformis flaccida, foliis alternis. Lin. Hort. Cliff. 197. *Naked shrubby Euphorbia without spines, taper flaccid branches, and leaves placed alternately. Tithymalus aphyllus Mauritania.* Hort. Elth. 384. *Mauritanian Spurge without leaves.*
17. **EUPHORBIA** (*Cotinifolia*) foliis oppositis subcordatis petiolatis emarginatis integerrimis, caule fruticoso. Lin. Sp. Plant. 453. *Euphorbia with heart-shaped leaves placed opposite upon foot-stalks, which are indented at the top, entire, and a shrubby stalk. Tithymalus arboreus Americanus cotini folio.* Hort. Amst. 1. p. 29. *Tree American Spurge with a Venice Smeach leaf.*
18. **EUPHORBIA** (*Lathyris*) umbellâ quadrifidâ, dichotomâ, foliis oppositis integerrimis. Lin. Sp. Plant.

457. *Euphorbia* with a quadrifid umbel, a forked stalk, and entire leaves placed opposite. *Tithymalus latifolius* Cataputia dictus. H. L. *Broad-leaved Spurge*, called *Cataputia*.
19. EUPHORBIA (*Myrsinites*) umbellâ suboctifidâ, bifidâ, involuclis subovatis, foliis spathulatio patentibus carnosius mucronatis margine scabris. Lin. Sp. Plant. 461. *Euphorbia* with an umbel divided into eight points, whose small involuclums are oval, and spreading fleshy-pointed leaves shaped like a spatula, having rough borders. *Tithymalus myrsinites latifolius*. C. B. P. 296. *Broad-leaved Myrtle Spurge*.
20. EUPHORBIA (*Dendroides*) umbellâ multifidâ, dichotomâ, involuclis subcordatis, primariis triphyllis, caule arboreo. Lin. Sp. Plant. 462. *Euphorbia* with a multifid forked umbel, heart-shaped small involuclums, the first three-leaved, and a tree-like stalk. *Tithymalus myrtifolius arboreus*. C. B. P. 290. *Myrtle-leaved Tree Spurge*.
21. EUPHORBIA (*Amygdaloides*) umbellâ multifidâ, dichotomâ, involuclis perfoliatis emarginatis, orbiculatis foliis obtusis. Lin. Sp. Plant. 662. *Euphorbia* with a multifid umbel divided by pairs, orbicular perfoliate involuclums, and obtuse leaves. *Tithymalus characias amygdaloides*. C. B. P. 290. *Wood Spurge*.
22. EUPHORBIA (*Palustris*) umbellâ multifidâ, subtrifidâ, bifidâ, involuclis ovatis, foliis lanceolatis, ramis sterilibus. Lin. Sp. Plant. 462. *Euphorbia* with a multifid umbel, which is subtrifid and bifid, the small involuclums oval, spear-shaped leaves, and sterile branches. *Tithymalus palustris fruticosus*. C. B. P. 292. *Skrubby Marsh Spurge*.
23. EUPHORBIA (*Orientalis*) umbellâ quinquefidâ, quadrifidâ, dichotomâ, involuclis subrotundis acutis, foliis lanceolatis. Lin. Sp. Plant. 460. *Euphorbia* with a quinquefid and quadrifid forked umbel, a pointed roundish involuclum, and spear-shaped leaves. *Tithymalus Orientalis*, foliis folio, caule purpureo, flore magno. Tourn. Cor. 2. *Eastern Spurge* with a Willow leaf, a purple stalk, and large flower.
24. EUPHORBIA (*Characias*) umbellâ quinquefidâ, trifidâ dichotomâ, involuclis ovatis, foliis lanceolatis, capsulis lanatis. Lin. Sp. Plant. 460. *Euphorbia* with a quinquefid trifid umbel, dividing by pairs, an oval involuclum, spear-shaped leaves and woolly capsules. *Tithymalus arboreus*, caule corallino, folio Hyperici, pericarpio barbato. Boerh. Ind. alt. 1. p. 256. *Tree Spurge* with a red stalk, a St. John's Wort leaf, and bearded capsule.
25. EUPHORBIA (*Hiberna*) umbellâ sextifidâ, dichotomâ, involuclis ovalibus, foliis integerrimis, ramis nullis capsulis verrucosis. Lin. Sp. Plant. 462. *Euphorbia* with a six-pointed forked umbel, oval involuclums, entire leaves, no branches, and warted capsules. *Tithymalus Hibernicus Machingboy dictus*. Mer. Pin. *Irish Spurge*, called *Machingboy*.
26. EUPHORBIA (*Apios*) umbellâ quinquefidâ, bifidâ, involuclis obcordatis. Lin. Sp. Plant. 457. *Euphorbia* with a quinquefid bifid umbel, and heart-shaped involuclums. *Tithymalus tuberosâ pyriformi radice*. C. B. P. 292. *Spurge* with a tuberous Pear-shaped root.
27. EUPHORBIA (*Aleppica*) umbellâ quinquefidâ, dichotomâ, involuclis ovato-lanceolatis mucronatis, foliis inferioribus setaceis. Lin. Sp. Plant. 458. *Euphorbia* with a quinquefid forked umbel, oval spear-shaped involuclums which are pointed, and the lower leaves bristly. *Tithymalus Cyparissius*. Alp. Exot. 65. *Cypress Spurge*.
28. EUPHORBIA (*Cretica*) umbellâ multifidâ, bifidâ, involuclis orbiculatis, foliis lineari-lanceolatis villosis. *Euphorbia* with a multifid bifid umbel, orbicular involuclums, and narrow, spear-shaped, hairy leaves. *Tithymalus Creticus characias*, angustifolius, villosus & incanus. Tourn. Cor. 1. *Cretan Wood Spurge*, with narrow, hairy, and hoary leaves.
29. EUPHORBIA (*Sylvatica*) umbellâ multifidâ, dichotomâ, involuclis perfoliatis, subcordatis, foliis lanceolatis integerrimis. Lin. Sp. Plant. 463. *Euphorbia* with a multifid forked umbel, heart-shaped perfoliate involuclums, and entire spear-shaped leaves. *Tithymalus*

- sylvaticus lunato flore*. C. B. P. 290. *Wood-Spurge* with a moon-shaped flower.
30. EUPHORBIA (*Heterophylla*) inermis foliis serratis petiolatis difformibus ovatis lanceolatis panduriformibus. Lin. Sp. Plant. 453. *Euphorbia* without spines, having sawed leaves with foot-stalks which are deformed, oval, spear-shaped, and like a fiddle. *Tithymalus Curallavicus*, foliis & atriplicis foliis variis, caulibus viridantibus. Pluk. Alm. 396. *Spurge* from Curassao, with variable leaves like Willow and Orach, and a green stalk.
31. EUPHORBIA (*Hypericifolia*) dichotomâ, foliis serratis ovali-oblongis glabris, corymbis terminalibus, ramis divaricatis. Lin. Sp. Plant. 454. *Forked Euphorbia* with oblong, oval, smooth, sawed leaves, and divaricated branches terminated by umbels. *Tithymalus erectus acris*, parietariæ foliis glabris, floribus ad caulum nodos conglomeratis. Sloan. Cat. Jam. 82. *Upright acrid Spurge*, with smooth Pellitory leaves, and flowers growing in clusters from the joints of the stalk.
32. EUPHORBIA (*Ocymoides*) inermis, herbacea, ramosa, foliis subcordatis integerrimis petiolatis floribus solitariis. Lin. Sp. Plant. 453. *Branching herbaceous Euphorbia* without spines, having entire heart-shaped leaves with foot-stalks, and single flowers. *Tithymalus Americanus*, erectus, annuus, ramosissimus ocymi caryophyllati foliis. Houst. MSS. *Upright, annual, branching Spurge of America*, with leaves like small Basil.
- The first sort has been generally taken for the true Euphorbium of the ancients, and as such hath been directed for medicinal use; but it is from the second sort, that the drug now imported under that title in England is taken. Dr. Linnæus supposes the fourth to be the sort which should be used, though as they are all nearly of the same quality, it may be indifferent which of them that drug is taken from, which is the inspissated juice of the plant.
- The first sort hath a triangular, compressed, succulent stalk, which is jointed, and rises to the height of eight or ten feet, sending out many irregular twisting branches, which are for the most part three-cornered, but have sometimes only two, and at others four angles; they are compressed, succulent, and spread out on every side the stalk; these have at the extremity of the branches a few short roundish leaves, which soon fall off; and near these come out now and then a few flowers, which have five thick whitish petals, with a large three-cornered germen in the center; these soon drop off without having any seeds. It grows naturally in India, from whence the plants were brought to the gardens in Holland, and have since been communicated to most of the curious gardens in Europe.
- The second sort grows naturally in the Canary Islands, from whence I have been credibly informed, the Euphorbium which is imported in England, is now brought, and is the inspissated juice of this plant. In its native country this grows to the height of twenty feet or more, but in England it is rarely seen more than six or seven; nor is it of any advantage to have them so tall here, because they send out many branches which are large and succulent, so render the plants too heavy to be easily removed. This hath a very thick, green, succulent stalk, which has four or five large angles or corners, closely armed with black crooked spines, which come out by pairs at every indenture: the stalks send out from every side large succulent branches of the same form, which extend to the distance of two or three feet, then turn their ends upwards, so that when the plants are well grown, they have some resemblance to a branched chandelier; these have no leaves, but are closely armed with black spines like the stalks; at the end of the branches come out the flowers, which are shaped like those of the first sort.
- The third sort hath a naked three-cornered stalk which is compressed, sending out a great number of branches which grow erect, and join up to the main stalk; these are generally three-cornered, but some vary to four; they are jointed and armed with short crooked spines, but have no leaves, nor do the plants

plants produce flowers here. This grows naturally in India.

The fourth sort puts out many stalks just above the surface of the ground, which are thick, succulent, and roundish, having eight or ten angles while they are young, but as they grow old they lose their angles and become round; the branches grow distorted and irregular, first horizontal, and afterward turn upward; they are armed with small crooked spines on their angles, and on the upper part of the branches come out the flowers, which are small, and of a greenish white, shaped like those of the second sort. This grows naturally in India.

The fifth sort grows naturally in India; this rises with a strong upright stalk five or six feet high, which hath irregular angles, and protuberances which are oblique to the angles; the lower part of the stalk is naked, the upper part is branching, and the branches are armed with crooked spines; at every protuberance, and at the top, they are garnished with oblong leaves of a lucid green, which are very smooth, entire, and rounded at their ends; these fall off, and the plants remain naked for some months; and then the flowers come out, which sit close to the branches, and are of a greenish white colour; the leaves come out in the autumn, and fall off in the spring.

The sixth sort rises with a roundish, upright, succulent stalk about three feet high, putting out several branches on the side of the same form; these have seven angles or furrows, which are armed with long, single, black thorns; at the end of which come out small flowers, of the same form with those of the other sorts, and are sometimes succeeded by small fruit.

The seventh sort hath thick, roundish, succulent stalks, which are scaly; these send out many branches from their sides of the same form, which are twisted, and run one over another, so as to appear like a parcel of serpents coming out from the stalks, from whence it had the appellation of Medusa's Head. The ends of the branches are garnished with narrow, thick, succulent leaves, which drop off, and round the upper part of the branches the flowers come out; these are white, and of the same form with those of the other species, but larger, and are frequently succeeded by round smooth capsules with three cells, each including a single roundish seed.

The eighth sort hath roundish stalks, which swell out like a belly in the middle, and have knobbed angles, between which come out long spines which are strait; these stalks rise two feet high, and put out a few branches on their side of the same form; the flowers are produced at the end of the branches, sitting close upon the angles; they are small, of a yellowish green colour, and shaped like those of the other species.

The ninth sort hath stalks and branches very like those of the fourth, but much slenderer; the spines of this are single, and those of the other double; and the ends of the branches are closely garnished with flowers on every angle, in which it differs from the fourth sort.

The tenth sort hath a thick short stalk, which seldom rises more than eight or ten inches high, from which come out a great number of trailing branches which are slender, and grow about a foot in length; these intermix with each other like those of the seventh sort, but they are much smaller, and do not grow near so long, but have the same appearance, from whence it is called Little Medusa's Head: the ends of these branches are beset with narrow leaves, between which the flowers come out, which are white, and shaped like those of the other species.

The eleventh sort rises with a taper stalk six or seven inches high, sending out from the top a few taper branches, which spread out on every side; these are not scaly, like those of the last sort, but taper, and garnished at their ends with several small narrow leaves which drop off. This sort hath not yet flowered here, having been but a short time in England.

The twelfth sort hath a short thick stalk, which never rises three inches high, so that the branches spread on the surface of the ground; these seldom grow more than six inches long, and their scales swell into a sort of protuberances which are square; they have no leaves, and very rarely produce flowers in England, but has been long an inhabitant in the gardens.

The thirteenth sort is very like the seventh, but the stalks never rise more than a foot or fifteen inches high, so that the branches spread out near the ground; these are also much shorter than those of the seventh, but have the same appearance, and are garnished with narrow leaves at their end, which fall off as the branches are extended in length: this produces a great number of small white flowers at the end of the branches, which are shaped like those of the other species, and are frequently succeeded by round smooth capsules with three cells, including one or two roundish seeds which ripen here.

These sorts have been by most of the modern botanists ranged under the title of Euphorbium, and have been distinguished from the Tithymali, more from the structure and outward appearance of the plants, than any real difference in their characters, as hath been before observed; but as the number of species of those commonly called Spurge was very great, so many of the writers were willing to separate the Euphorbia from that genus, to lessen the number of species.

These plants are preserved in many curious gardens, more for the oddness of their structure, than any real beauty; but being so extremely different in their form, from almost any plants of European production, many curious persons have been induced to preserve the several sorts in their gardens.

They are all of them full of a milky acrid juice, which flows out on their being wounded in any part; this juice will blister the flesh, if it happen to lie upon any tender part for a short time, and will burn linen almost as bad as aqua fortis, therefore the plants should be handled with great caution; nor should the ends of their branches be ever bruised or injured; for if they are, it frequently occasions their rotting down to the next joint, and sometimes will destroy the whole plant, if those injured branches are not cut off in time; so that whenever the branches appear to have been injured, the sooner they are cut from the plants, the less danger there will be of their suffering from it; nor should any of the branches be cut between the joints, for the same reason.

Most of these plants were first brought to Europe by the Dutch, who have been very curious to introduce great numbers of plants from India, and also from the Cape of Good Hope: from the latter there hath been a very great variety of curious plants of late years brought to Europe, many of which produce very elegant flowers, and are the greatest ornaments of the conservatory in the winter and spring seasons. These have been brought over in seeds, but the different kinds of Euphorbia came over most of them in plants or cuttings; for these may be easily transported to any distance, if either of them are put up in boxes, with any soft dry package, to prevent their being bruised, or their spines from wounding each other, and kept from moisture and cold; with this care they may be kept six months out of the ground, and if carefully planted will take root, and thrive as well as if they had been newly taken from the old plants, or out of the ground but a short time; which is a much more expeditious method of obtaining the plants than from seeds, when they can be procured.

The greatest part of these succulent plants grow naturally upon barren rocky places, or in dry sandy soils, where few other plants will thrive; therefore they should never be planted in rich or loamy earth here, nor suffered to receive much wet, which will cause them to rot. The best mixture of earth for these plants is about a fourth part of screened lime-rubbish, a fourth part of sea-sand, and half of light fresh earth from a common; these should be mixed well

well together, and frequently turned over before it is used, that the parts may be incorporated, and the compost sweetened by being exposed to the air. If this mixture is prepared a year before it is wanted, it will be the better, that it may have the benefit of the winter's frost and the summer's heat to mellow it; and the oftener it is turned over, and the smaller the heaps are in which it is laid, the air will penetrate it better, and render it more fit for use.

These sorts are easily propagated by cuttings, which should be taken from the old plants in June; these must be cut at a joint, otherwise they will rot. When these cuttings are taken off, the milky juice of the old plants will flow out in plenty; therefore there should be some dry earth or sand applied upon the wounded part, which will harden and stop the sap; and the wounded part of the cuttings should also be rubbed in sand, or dry earth, for the same purpose; then the cuttings should be laid in a dry part of the stove, for ten days or a fortnight; and some of those whose branches are large and very succulent, may lie three weeks or more before they are planted, that their wounds may be healed and hardened, otherwise they will rot. When the cuttings are planted, they should be each put into a small halfpenny pot, laying stones or rubbish in the bottom, and filling the pots with the mixture before directed; then plunge the pots into a moderate hot-bed, and if the weather is very hot, the glasses of the hot-bed should be shaded in the middle of the day, and the cuttings should be gently watered once or twice a week, according as the earth may dry: in about six weeks or two months the cuttings will have put out roots, so if the bed is not very warm, the plants may continue there, provided they have free air admitted to them every day, otherwise it will be better to remove them into the stove, where they may be hardened before the winter; for if they are too much drawn in summer, they are very apt to decay in winter, unless they are very carefully managed. During the summer season, these plants should be gently watered two or three times a week, according to the warmth of the season; but in winter they must not be watered oftener than once a week, and it should be given more sparingly at that season, especially if the stove is not warm: the first sort will require more warmth in the winter than any of the other, as also less water at that season. This, if well managed, will grow seven or eight feet high; but the plants must constantly remain in the stove, giving them a large share of air in warm weather, and in winter the stove should be kept in a temperate degree of warmth.

The sixth sort is at present the most rare in England: the plants of this sort, which have been procured from Holland, have been most of them destroyed by placing them in stoves, where, by the heat, they have in one day turned black, and rotted immediately after. This sort will thrive well if placed in a dry airy glass-case with *Ficoides*, and other succulent plants in the winter, where they may have free air in mild weather, and be protected from frost; in summer the plants of this sort may be exposed in the open air, in a warm situation, but should be screened from much wet: with this treatment, the plants will thrive much better than when they are more tenderly nursed.

The seventh, eighth, tenth, eleventh, twelfth, and thirteenth sorts, are also pretty hardy, so will live in a good glass-case in winter without fire, provided the frost is kept entirely out, and in summer they may be placed abroad in a warm situation: as these are very succulent plants, they should not have too much wet; therefore, if the summer should prove very moist, it will be very proper to place these plants under some shelter, where they may enjoy the free air, and be screened from the rain, otherwise by receiving too much wet in summer they will rot in winter. The seventh sort will require to be supported, otherwise the weight of the branches will draw them upon the pots; and, by training of the stems up to stakes,

they will grow four or five feet high, and a great number of side branches will be produced; these, being very succulent and heavy, are very apt to draw down the stem if it hath not support.

The following sorts have been, by all the writers on botany, placed under the title of *Tithymalus*; but the fourteenth and fifteenth sorts should, according to their own distinction, have been placed in the genus of *Euphorbium*, because they are as destitute of leaves as most of the species which they have there placed.

The fourteenth sort rises with a taper succulent stalk to the height of eighteen or twenty feet, sending out many branches of the same form, which subdivide into many smaller; these are jointed but at a great distance: they are smooth, and of a deep green colour, having a few small leaves at their extremities, which soon fall off. As the plants grow older, their stalks become stronger and less succulent, especially toward the bottom, where they turn to a brown colour, and become a little woody. The branches grow diffused and intermix with each other, so form a sort of bush toward the top, but this doth not produce flowers here.

The fifteenth sort sends out a great number of slender taper stalks of a dark green colour, which are smooth, and twist about each other, or any neighbouring support, whereby they will rise to the height of ten or twelve feet, putting out smaller branches upward, which also twine and intermix with the other stalks; they are naked, having no leaves, nor do the plants flower in England. These grow in India.

The sixteenth sort sends out many taper succulent stalks from the root, which rise about four feet high; they are slender and weak, so require support to prevent their falling to the ground; these have a light green bark, and their lower parts are naked, but their upper parts are garnished with oblong leaves, which are smooth, entire, and placed alternate on every side the stalks: the flowers are produced in small clusters at the end of the branches, they are of a yellowish green colour, and are sometimes succeeded by smooth round fruit, but the seeds rarely ripen in England. This sort grows naturally on the African shore in the Mediterranean.

The seventeenth sort grows naturally in some of the islands of the West-Indies, and also upon the continent there. I received specimens of this sort from the island of Tobago, and also from Carthage, where the plants were growing in plenty; the Dutch gardens were furnished with it from Curassao, where it also grows naturally. This hath an upright stalk, which rises to the height of six or seven feet, covered with a light brown bark, and divides upward into many branches; these are garnished with roundish leaves, which are indented at their ends, and have foot-stalks: they are smooth and of a beautiful green, but fall away in winter, so that in the spring they are almost naked; the flowers come out from the end of the branches, they are yellow and small, soon falling away without having any fruit succeed them here.

These sorts are propagated by cuttings, in the same manner as the *Euphorbiums*, and the plants must be treated in the same way, as hath been directed for them.

The fourteenth, fifteenth, and seventeenth sorts, are tender, so require a stove; these must have the same treatment as the tender kinds of *Euphorbiums*, but the sixteenth sort will live in a common green-house in winter, and may be exposed abroad in the summer. The eighteenth sort stands in the list of medicinal plants, but is rarely used in England at present; this is a biennial plant, which perishes after the seeds are ripe. It grows naturally in Italy and the south of France, and where it is allowed to scatter its seeds in a garden, becomes a weed here. This rises with an upright succulent stalk from three to four feet high, garnished with oblong smooth leaves which are placed opposite, and sit close to the stalks; the upper part of the stalk divides by pairs into smaller forked

E U P

branches, and from the fork between these divisions come out the umbels of flowers, each fork having one; that which is situated in the first division being the largest, and those in the upper the smallest. The flowers are of a greenish yellow colour; they appear in June and July, and the fruit follows soon after, which is divided into three lobes, and has three cells, each containing one roundish seed, which is cast out at a distance by the elasticity of the pods. This sort will propagate itself fast enough when it is once introduced into gardens, so requires no care but to keep it clean from weeds.

The nineteenth sort grows naturally in the south of France, in Spain, and Italy. This sends out many trailing branches from the root, which grow about a foot long, lying upon the ground, which are closely garnished with thick succulent leaves; these are flat, short, and pointed; they spread open on every side the branches, and are placed alternate, sitting close to the stalks: the flowers are produced in large umbels at the end of the branches; the involucre of the principal umbel is composed of several oval-pointed leaves, but those of the small umbels have only two heart-shaped concave leaves, whose borders are rough; the flowers are yellow, and are succeeded by three seeds, inclosed in a roundish capsule with three cells. This plant will continue two or three years upon a dry warm soil, and will ripen seeds annually; which, if permitted to scatter, the plants will come up, and require no other care but to keep them clean from weeds.

The twentieth sort grows naturally in Crete, and in several islands of the Archipelago; this rises with an upright branching stem to the height of four feet; the leaves of this are oblong and pointed, and are placed alternate on the branches; the flowers come out in umbels from the fork between the branches; they are small and yellow, and are rarely succeeded by seeds in England. It is easily propagated by cuttings during any of the summer months, and requires a little protection from the frost in winter.

The twenty-first sort grows naturally in the woods in many parts of England; it rises with a shrubby stalk three feet high; the flowers are produced in umbels sitting close to the stalks, so form a long spike; the empalements are of a greenish yellow, and the petals black, so they make an odd appearance. It flowers in May, and the seeds ripen in July. If the seeds of this are sown under trees in the autumn, the plants will rise the following spring, and require no culture.

The twenty-second sort stands in the list of medicinal plants by the title of *Esula major*, but at present is seldom used: this grows naturally in France and Germany upon marshy places, where it rises three or four feet high. It hath a perennial root, by which it may be propagated better than by seeds, which seldom grow, unless they are sown soon after they are ripe.

The twenty-third sort was discovered in the Levant, by Dr. Tournefort, who sent the seeds to the royal garden at Paris; this hath a perennial root, from which arise many succulent stalks three feet high, covered with a purple bark, and garnished with oblong smooth leaves, shaped like those of Willow, of a dark green colour. The upper part of the stalks divide, and in the fork is situated an umbel of flowers of a greenish yellow colour, which are succeeded by round capsules with three cells, each containing a single seed. It flowers in June, and the seeds are ripe in August; this may be propagated by parting the roots, or by sowing the seeds in autumn. The plant is hardy, so will endure the greatest cold of this country, if it is planted in a dry soil.

The twenty-fourth sort grows naturally in Sicily, and on the borders of the Mediterranean Sea; this rises with several shrubby stalks to the height of five or six feet, having a red bark, and are garnished with oblong, smooth, blunt leaves, which are placed alternate. The flowers grow in small umbels from the

E U P

division of their branches; they are yellow, and are succeeded by roundish capsules, which are rough, having three cells like the other species. This is easily propagated by cuttings during any of the summer months, and requires protection from the frost in winter.

The twenty-fifth sort grows naturally in Ireland, from whence the roots have been brought to England; this hath thick fibrous roots, which send up several single unbranched stalks about a foot high, garnished with oblong leaves, placed alternate on every side. The flowers are produced in small umbels at the top of the stalks; they are yellow, and are succeeded by rough warted capsules with three cells; it flowers in June, and the seeds ripen in August. This may be propagated by the roots, which should be planted in a shady situation and a moist soil.

This plant was almost the only physic used by the native inhabitants of Ireland formerly; but since the use of mercury has been known to them, the other has been generally neglected.

The twenty-sixth sort grows naturally in the Levant; this hath a knobbed Pear-shaped root, from which arise two or three stalks about a foot and a half high, garnished with oblong leaves, which are hairy, placed alternate on every side the stalk. The flowers are produced in small umbels from the divisions of the stalk; they are small, of a greenish yellow colour, and are seldom succeeded by seeds here; it may be propagated by offsets, sent out from the main root; these may be taken off in autumn, and planted in a shady situation, where they will thrive better than in the full sun.

The twenty-seventh sort grows naturally at Aleppo, and in other parts of the Levant; this hath a perennial creeping root, by which it multiplies very fast where it is once established. The stalks of this rise a foot and a half high; the lower leaves are narrow, stiff, and bristly; but those on the upper part of the stalk are shaped like the narrow-leaved Myrtle. The flowers are produced in large umbels from the divisions of the stalk; they are yellow, and appear in June, but are rarely succeeded by seeds in this country. The roots of this should be confined in pots; for when they are planted in the full ground, they creep about to a great distance.

The twenty-eighth sort grows naturally in many parts of the Levant, and also in Spain and Portugal. The seeds of this were brought me from Scanderoon, by the late Mr. Robert Millar, who found the plants growing plentifully there; and he assured me, that he saw the inhabitants wounding of these plants, and collecting their milky juice, which they mixed up with the Scammony to send abroad.

The seeds of this plant were since sent me from Portugal, by Robert More, Esq; who found the plants growing there naturally, but this plant had been many years before an inhabitant in the English gardens; this rises with a purple shrubby stalk near three feet high, which is garnished with narrow, spear-shaped, hairy leaves, set closely on the stalk alternately on every side; the upper part of the stalk is terminated by umbels of flowers, which form a sort of spike. The greater umbels are multifid, but the small ones are bifid. The involucres of the flowers are yellow, and the petals of the flowers black; these appear in May, and are succeeded by seeds which ripen in July: the young plants which have been lately raised from seeds, are generally very fruitful, but the old ones, and those raised by cuttings are barren; this may be propagated by seeds, or from cuttings, and will live abroad if planted in a dry rubbishy soil and a warm situation, otherwise they are frequently killed by severe frost.

The twenty-ninth sort grows naturally in the south of France, in Spain, and Italy; this is a biennial plant, from whose root arise two or three stalks, which grow two or three feet high, garnished with spear-shaped leaves, which are entire. The umbels of flowers arise from the division of the branches; the involucres are

E U P

are heart-shaped, and surround the pedicle with their base. The flowers are yellow, and appear in June. The seeds ripen in August; which, if permitted to scatter, the plants will come up, and require no other care but to keep them clean from weeds; this must have a shady situation.

The thirtieth sort grows naturally at La Vera Cruz, from whence the late Dr. Houstoun sent me the seeds; this is an annual plant, which rises from two to three feet high. The leaves of these are sometimes narrow and entire, at other times oval, and divided in the middle, almost to the midrib, in shape of a fiddle; they also vary in their colour, some being inclinable to purple, others of a light green; they are sawed on their edges, and stand upon short foot-stalks. The flowers are produced in small umbels at the end of the branches; they are of a greenish white, and are succeeded by small round capsules with three cells.

The thirty-first sort grows naturally in most of the islands in the West-Indies; this is an annual plant, which rises with a branching stalk about two feet high, garnished with oblong, oval, smooth leaves, which are sawed on the edges. The flowers grow in small umbels at the foot-stalks of the leaves, gathered into close bunches; these are white, and are succeeded by small round capsules, inclosing three seeds.

The seeds of the thirty-second sort were sent me from La Vera Cruz, by the late Dr. Houstoun; this is an annual plant, which rises with an upright stalk

E X O

about a foot high, dividing into a great number of branches, which spread very wide on every side, garnished with roundish, heart-shaped leaves, which are entire, standing upon pretty long foot-stalks. The flowers come out singly from the divisions of the stalk; they are small, and of an herbaceous colour, and are succeeded by small round capsules, containing three seeds.

The last three sorts are annual; the seeds of these must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a small pot filled with light earth, and plunged into the hot-bed again, and must afterward be treated in the same manner as other tender annual plants from warm countries.

EUPHRASIA. Eyebright.

This is a medicinal plant, which grows naturally in the fields and commons in most parts of England, always among grass, heath, furz, or some other cover, and will not grow when these are cleared from about it; nor will the seeds grow when they are sown in a garden; for which reason I shall not trouble the reader with a description, or any farther account of it, than that the herb-women supply the markets with it in plenty from the fields.

EXCORTICATION [excortatio, *Lat.*] a pulling or peeling off the outward bark of trees.

EXOTICS [exotica, *Lat.*] Exotic plants are such as are natives of foreign countries.

F A B

FABA. Tourn. Inst. R. H. 391. tab. 212. Vicia. Lin. Gen. Plant. 782. The Bean; in French, *Fève*.

The CHARACTERS are,

The flower hath a tubulous empalement of one leaf, which is cut into five segments at the brim; the three lower segments being long, and the two upper are very short. The flower is of the butterfly kind. The standard is large, oval, and indented at the end; the two sides turn backward, after some time; it hath two oblong erect wings, which inclose the keel, being much longer. The keel is short, swelling, and closely covers the parts of generation; these are joined in one column, almost to the top where they are divided; the nine stamina are in three parts, and one stands separate; these are terminated by roundish reclined summits. At the bottom is situated an oblong compressed germen, supporting a short angular style, crowned by an obtuse stigma, which is bearded on the two sides. The germen afterward becomes a long, compressed, leathery pod, having one cell, filled with compressed kidney-shaped seeds.

Tournefort ranges this genus of plants in the second section of his tenth class, which includes the herbs with a butterfly flower, whose pointal turns to a long pod with one cell. This is in the third section of Linnæus's seventeenth class, in which he places those plants whose flowers have ten stamina, joined in two bodies; and he joins it to his genus of Vicia, so he makes only a specific difference between them; but as the Bean hath a compressed leathery pod and kidney-shaped seeds, and the Vetch a swelling pod with round seeds, they should be separated.

F A B

There are several varieties of the Garden Bean, which are known and distinguished by the gardeners, but do not essentially differ from each other; so I shall not enumerate them as distinct species, nor join these to the Horse Bean, as some have done, who have supposed them to be but one species; for, from having cultivated them more than forty years, without finding the Garden Bean degenerate to the Horse Bean, or the latter improving to the former, I conclude they are distinct species.

There is a great variety of the Garden Beans, now cultivated in the kitchen-gardens in England, which differ in size and shape; some of them producing their pods much earlier in the year than others, for which they are greatly esteemed by the gardeners, whose profit arises from their early crops of most esculent plants; therefore they are very careful to improve all those varieties which have a tendency to be fit for the markets first; but as many sorts of seeds, when cultivated long in the same land, are apt to degenerate, so new seeds should be annually procured, either from abroad, or some distant situation, where the soil is of a different nature, by which change many of the varieties may be continued in perfection.

I shall begin with the Garden Bean, called by the botanists, *Faba major* to distinguish it from the Horse Bean, which they have titled *Faba minor* seu *Equina*; and I shall only mention the names of each, by which they are known among the gardeners, placing them according to their time of ripening for the table.

The Mazagan Bean is the first and best sort of early Beans at present known; these are brought from a settlement

tlement of the Portuguese on the coast of Africa, just without the Straights of Gibraltar; the seeds of this sort are smaller than those of the Horse Bean; and as the Portuguese are but slovenly gardeners, there is commonly a great number of bad seeds among them. If this sort is sown in October, under a warm hedge, pale, or wall, and carefully earthed up when the plants are advanced, they will be fit for the table by the middle of May. The stems of this sort are very slender, therefore, if they are supported by strings close to the hedge, or pale, it will preserve them from the morning frosts, which are sometimes severe in the spring, and retard their growth; so by keeping them close to the fence it will cause them to come forwarder than if this is neglected; these Beans bear plentifully, but they ripen nearly together, so that there are never more than two gatherings from the same plants; if the seeds of this sort are saved two years in England, the Beans will become much larger, and not ripen so soon, which is called a degeneracy.

The next sort is the early Portugal Bean, which appears to be the Mazagan sort saved in Portugal, for it is very like those which are the first year saved in England; this is the most common sort used by the gardeners for their first crop, but they are not near so well tasted as the Mazagan; therefore when the Mazagan Bean can be procured, no person would plant the other.

The next is the small Spanish Bean; this will come in soon after the Portugal sort, and is rather a sweeter Bean, therefore should be preferred to it.

Then comes the broad Spanish, which is a little later than the other, but comes in before the common sorts, and is a good bearer, therefore is frequently planted.

The Sandwich Bean comes soon after the Spanish, and is almost as large as the Windsor Bean; but, being hardier, is commonly sown a month sooner; this is a plentiful bearer, but not very delicate for the table.

The Toker Bean, as it is generally called, comes about the same time with the Sandwich, and is a great bearer; therefore is now much planted, though it is a coarse Bean.

The white and black Blossom Beans are also by some persons much esteemed; the Beans of the former are, when boiled, almost as green as Peas; and being a tolerable sweet Bean, renders it more valuable; these sorts are very apt to degenerate, if their seeds are not saved with great care.

The Windsor Bean is allowed to be the best of all the sorts for the table; when these are planted on a good soil, and are allowed sufficient room, their seeds will be very large, and in great plenty; and when they are gathered young, are the sweetest and best tasted of all the sorts; but these should be carefully saved, by pulling out such of the plants as are not perfectly right, and afterward by sorting out all the good from the bad Beans.

This sort of Bean is seldom planted before Christmas, because it will not bear the frost so well as many of the other sorts; so it is generally planted for the great crop, to come in June and July.

All the early Beans are generally planted on warm borders under walls, pales, and hedges; and those which are designed to come first, are usually planted in a single row pretty close to the fence: and here I cannot help taking notice of a very bad custom, which too generally prevails in gentlemens kitchen-gardens, which is that of planting Beans close to the garden-walls, on the best aspects, immediately before the fruit-trees, which is certainly a greater prejudice to the trees, than the value of the Beans, or any other early crop; therefore this practice should be everywhere discouraged; for it is much better to run some low Reed hedges across the quarters of the kitchen-garden, where early Beans and Peas may be planted, in which places they may with more conveniency be covered in severe frost; and to these hedges they may both be closely fastened, as they advance in their growth; which, if practised against the walls where

good fruit-trees are planted, will greatly prejudice the trees, by overshadowing them, and the growth of these legumes will draw off the nourishment from the roots of the trees, whereby they will be greatly weakened.

But to return to the culture of the Beans. Those which are planted early in October, will come up by the beginning of November; and as soon as they are an inch above ground, the earth should be carefully drawn up with a hoe to their stems; and this must be two or three times repeated, as the Beans advance in height; which will protect their stems from the frost, and encourage their strength. If the winter should prove severe, it will be very proper to cover the Beans with Peas-haulm, Fern, or some other light covering, which will secure them from the injury of frost; but this covering must be constantly taken off in mild weather, otherwise they will draw up tall and weak, and come to little; and if the surface of the border is covered with tanners bark, it will prevent the frost penetrating the ground to the roots of both, and be of great service to protect them from the injury which they might otherwise receive.

In the spring, when the Beans are advanced to be a foot high, they should be fastened up to the hedge with packthread or a small line, so as to draw them as close as possible; which will secure them from being injured by the morning frosts, which are often so severe in March and April, as to lay those Beans flat on the ground, which are not thus guarded; at this time all suckers which come out from the roots should be very carefully taken off; for these will retard the growth of the Beans, and prevent their coming early; and when the blossoms begin to open toward the bottom of the stalks, the top of the stems should be pinched off, which will cause those first pods to stand, and thereby bring them forward. If these rules are observed, and the ground kept clean from weeds, or other plants, there will be little danger of their failing.

But lest this first crop should be destroyed by frost, it will be absolutely necessary to plant more about three weeks after the first, and so to repeat planting more every three weeks, or a month, till February; but those which are planted toward the end of November, or the beginning of December, may be planted on sloping banks, at a small distance from the hedges; for if the weather is mild, these will not appear above ground before Christmas; therefore will not be in so much danger as the first and second planting, especially if the surface of the ground is covered with tan to keep the frost out of the ground as is before directed; for the first planting will, by that time, be a considerable height: the same directions which are before given will be sufficient for the management of these; but only it must be observed, that the larger Beans should be planted at a greater distance than the small ones; as also, that those which are first planted must be put closer together, to allow for some miscarrying; therefore, when a single row is planted, the Beans may be put two inches asunder, and those of the third and fourth planting may be allowed three inches; and when they are planted in rows across a bank, the rows should be two feet and a half asunder; but the Windsor Beans should have a foot more space between the rows, and the Beans in the rows should be planted five or six inches asunder. This distance may, by some persons, be thought too great; but from many years experience, I can affirm, that the same space of ground will produce a greater quantity of Beans when planted at this distance, than if double the quantity of seeds are put on it. In the management of these later crops of Beans, the principal care should be to keep them clear from weeds, and any other plants which would draw away their nourishment; to keep earthing them up, and, when they are in blossom, to pinch off their tops; which, if suffered to grow, will draw the nourishment from the lower blossoms, which will prevent the pods from setting, and so only the upper parts of the stems will be fruitful,

fruitful; and another thing should be observed in planting of the succeeding crops, which is, to make choice of moist strong land for the later crops; for if they are planted on dry ground, they rarely produce a crop.

These after-crops should be planted at about a fortnight distance from each other, from the middle of February to the middle of May; after which time it is generally too late to plant, unless the land is very strong and moist; for in warm dry light land all the late crops of Beans are generally attacked by the black insects, which cover all the upper part of their stems, and soon cause them to decay.

Where the seeds of these Beans are designed to be saved, a sufficient number of rows should be set apart for that purpose, according to the quantity desired; these should be managed in the same way as those which are designed for the table; but none of the Beans should be gathered, though there are some covetous persons, who will gather all the first ripe for the table, and are contented to save the after-crop for seed, but these are never so large and fair as the first; so that if these are for sale, they will not bring near the price as the other; therefore, what is gained to the table is lost in the value of the seed; but those who are desirous to preserve the several varieties as pure as possible, should never suffer two of the varieties to grow for seeds in the same place; for by their farina mixing with each other they will not continue so pure, but be apt to vary; and in order to keep the early kinds perfect, those which come the earliest should be saved for seeds; but this is what few people chuse to do, because they are then the most valuable.

When the seed is ripe, the stalks should be pulled up, and set upright against a hedge to dry, observing to turn them every third day, that they may dry equally; then they may be threshed out, and cleaned for use, or otherwise stacked up in a barn, till there is more leisure for threshing them out; and afterward the seed should be drawn over to take out all those that are not fair, preserving the best for use or sale.

It is a very good method to change the seeds of all sorts of Beans, and not to sow and save the seeds long in the same ground, for they do not succeed so well; therefore, if the land is strong where they are to be planted, it will be the best way to procure the seeds from a lighter ground, and so vice versa; and by this method the crops will be larger, and the Beans fairer, and not so liable to degenerate.

Having given directions for the culture of the Garden Beans, I shall next proceed to that of the Horse Bean, which is cultivated in the fields: there are two or three varieties of these Beans, which differ in their size and colour; but that which is now in the greatest esteem, is called the Tick Bean; this doth not grow so high as the other, is a more plentiful bearer, and succeeds better on light land than the common Horse Bean, so preferred to it.

The Horse Bean delights in a strong moist soil, and an open exposure, for they never thrive well on dry warm land, or in small inclosures, where they are very subject to blight, and are frequently attacked by a black insect, which the farmers call the black dolphin; these insects are often in such quantities as to cover the stems of the Beans entirely, especially all the upper part of them; and whenever this happens, the Beans seldom come to good; but in the open fields, where the soil is strong, this rarely happens.

These Beans are usually sown on land which is fresh broken up, because they are of use to break and pulverize the ground, as also to destroy weeds; so that the land is rendered much better for corn, after a crop of Beans, than it would have been before, especially if they are sown and managed according to the new husbandry, with a drill plough, and the horse hoe, used to stir the ground between the rows of Beans, which will prevent the growth of weeds, and pulverize the ground, whereby a much greater crop

of Beans may, with more certainty, be expected, and the land will be better prepared for whatever crop it is designed for after.

The season for sowing of these Beans is from the middle of February to the end of March, according to the nature of the soil; the strongest and wet land should always be last sown; the usual quantity of Beans sown on an acre of land is about three bushels; but this is double the quantity which need be sown, especially according to the new husbandry; but I shall first set down the practice according to the old husbandry, and then give directions for their management according to the new. The method of sowing is after the plough, in the bottom of the furrows; but then the furrows should not be more than five, or at most six inches deep. If the land is new broken up, it is usual to plough it early in autumn, and let it lie in ridges till after Christmas; then plough it in small furrows, and lay the ground smooth; these two ploughings will break the ground fine enough for Beans, and the third ploughing is to sow the Beans, when the furrows should be made shallow, as was before mentioned.

Most people set their Beans too close; for, as some lay the Beans in the furrows after the plough, and others lay them before the plough, and plough them in; so, by both methods the Beans are set as close as the furrows are made, which is much too near; for when they are on strong good land, they generally are drawn up to a very great height, and are not so apt to pod as when they have more room, and are of lower growth; therefore I am convinced by many late trials, that the better way is to make the furrows two feet and a half asunder, or more; which will cause them to branch out into many stalks, and bear in greater plenty than when they are closer; by this method, half the quantity of Beans will be sufficient for an acre of land; and by the sun and air being admitted between the rows, the Beans will ripen much earlier and more equally than in the common way.

What has been mentioned must be understood as relating to the old husbandry; but where Beans are planted according to the new, the ground should be four times ploughed before the Beans are set, which will break the clods, and render it much better for planting; then with a drill plough, to which a hopper is fixed for setting of the Beans, the drills should be made at three feet asunder, and the spring of the hopper set so as to scatter the Beans at three inches distance in the drills. By this method less than one bushel of seed will plant an acre of land. When the Beans are up, if the ground is stirred between the rows with a horse plough, it will destroy all the young weeds; and when the Beans are advanced about three or four inches high, the ground should be again ploughed between the rows, and the earth laid up to the Beans; and if a third ploughing, at about five or six weeks after is given, the ground will be kept clean from weeds, and the Beans will stalk out, and produce a much greater crop than in the common way.

When the Beans are ripe, they are reaped with a hook, as is usually practised for Peas; and after having lain a few days on the ground they are turned, and this must be repeated several times, until they are dry enough to stack; but the best method is to tie them in small bundles, and set them upright; for then they will not be in so much danger to suffer by wet, as when they lie on the ground; and they will be more handy to carry and stack, than if they are loose. The common produce is from twenty to twenty-five bushels on an acre of land; but I have known thirty-six on an acre.

The Beans should lie in the mow to sweat, before they are threshed out; for as the haulm is very large and succulent, so it is very apt to give and grow moist; but there is no danger of the Beans receiving damage, if they are stacked tolerably dry, because the pods will preserve the Beans from injury; and they will be much easier to thresh after they have sweat in the

now than before; and after they have once sweated and are dry again, they never after give.

By the new husbandry, the produce has exceeded the old by more than ten bushels on an acre; and if the Beans which are cultivated in the common method are observed, it will be found that more than half their stems have no Beans on them; for by standing close, they are drawn up very tall; so the tops of the stalks only produce, and all the lower part is naked; whereas in the new method, they bear almost to the ground; and as the joints of the stems are shorter, so the Beans grow closer together on the stalks.

In the year 1745 I made the following experiment, in planting a piece of eleven acres of Beans in Berkshire, viz. the gentleman's bailiff, who was wedded to the old practice of husbandry, was very unwilling to depart from it; and having been an old servant in the family, his master was inclinable to hear all he could say in favour of his opinion: however, at last I prevailed on the gentleman to let his bailiff plant one half of the land in his way, giving him the choice which half he would have: accordingly the land was divided and planted; but the summer proving wet, the Beans on that part of the field he had chosen grew so tall and rank, that they produced no pods but on the upper part of the stalks; and when they were threshed out, there was no more than twenty-two bushels on an acre, whereas the other half produced near forty.

FABA ÆGYPTIACA, is the Arum Ægyptiacum.

FABA CRASSA, is Anacampseros.

FABAGO. See ZYGOPHYLLUM.

FAGARA. Brown. Hist. Jam. tab. 5. f. 1. Ironwood.

The CHARACTERS are,

It hath male and hermaphrodite flowers upon different plants; the male flowers have a small empalement, slightly cut into four segments, but have no petals, and six stamina, terminated by roundish summits: these are barren. The female flowers have a larger concave permanent empalement with four spreading petals, and four stamina, crowned with oval summits, and an oval germen, supporting a slender style, terminated by an obtuse stigma; the germen afterward becomes a globular capsule with two lobes, inclosing two seeds.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia; whereas it should be put into his sixth section of the twenty-third class, as the flowers are male and hermaphrodite on different plants, and the flowers have six stamina: but this mistake he was led into by Jacquin, who had seen and described the hermaphrodite flowers only.

The SPECIES are,

1. FAGARA (*Pterota*) foliolis emarginatis. Amoen. Acad. 5. p. 393. *Fagara*, whose lobes (or small leaves) are indented at the top. Lauro affinis jasmini alato folio, costa media membranulis utrinque extantibus alata, ligno duritie ferro vix cedens. Sloan. Hist. Jam. 2. p. 25. Ironwood.

2. FAGARA (*Tragodes*) articulis pinnarum subtus aculeatus. Jacq. Amer. 13. *Fagara* with spines under the leaves at the joints. Schinoides petiolis subtus aculeatis. Hort. Cliff. 489.

The first sort grows naturally in the warmest parts of America. The late Dr. Houstoun found it growing at Campeachy, from whence he sent me dried specimens of the plants in flower, by which I am convinced there are male trees which are barren. It rises with a woody stem upwards of twenty feet high, sending out branches great part of its length, garnished with small winged leaves, having three or five lobes to each. The flowers come from the side of the branches, standing four or five together upon short foot-stalks.

The second sort I have placed here after Linnæus, but am not sure it should be ranged with it; for although I have pretty strong plants of it growing in the Chelsea garden, they have not yet flowered; but by the external face of the plant, it seems to agree with the first.

These are both tender plants, so must be kept in the bark-stove constantly, and are propagated by seeds, and also by cuttings, if properly managed.

FAGONIA. Tourn. Int. R. H. 265. tab. 141. Lin. Gen. Plant. 475. This plant was so named by Dr. Tournefort, in honour of Dr. Fagon, who was superintendant of the royal garden at Paris.

The CHARACTERS are,

The flower hath a spreading empalement, composed of five small leaves; it hath five heart-shaped petals, which spread open, and are narrow at their base, where they are inserted in the empalement. It hath ten stamina which are erect, terminated by roundish summits. In the center is situated a five-cornered germen, supporting an awl-shaped style, crowned by a single stigma. The germen afterward becomes a roundish capsule having five lobes, ending in a point, and five cells, each having a single roundish seed.

Linnæus ranges this plant in the first section of his tenth class, intitled Decandria Monogynia, from the flower having ten stamina and one style.

The SPECIES are,

1. FAGONIA (*Erecta*) spinosa, foliolis lanceolatis planis lævibus. Hort. Uplal. 103. *Prickly Fagonia*, whose leaves are spear-shaped, plain, and smooth. Fagonia Cretica spinosa. Tourn. *Thorny Trefoil of Candia*.
2. FAGONIA (*Hispanica*) inermis. Lin. Sp. Plant. 386. *Fagonia* without spines. Fagonia Hispanica non spinosa. Tourn. *Spanish Fagonia without thorns*.
3. FAGONIA (*Arabica*) spinosa, foliolis linearibus convexis. Lin. Sp. Plant. 386. *Prickly Fagonia with narrow convex leaves*. Fagonia Arabica, longissimis aculeis armato. Shaw. Pl. Afr. 229. *Arabian Fagonia, armed with very long spines*.

The first sort is a native of the island of Candia: this has been described by some botanists under the title of Trifolium spinosum Creticum, which occasioned my giving it the English name of Thorny Trefoil of Crete; though there is no other affinity between this and the Trefoil, than that of this having three leaves or lobes on the same foot-stalk.

This is a low plant, which spreads its branches close to the ground, which are extended to the length of a foot or more every way, garnished with small trifoliate oval leaves, placed opposite; and at each joint, immediately below the leaves, come out two pair of spines, one on each side the stalk; and at the same places come out a single blue flower, standing upon a short foot-stalk, composed of five spear-shaped petals, which are narrow at their base, where they are inserted into the empalement; after these fall away, the germen turns to a roundish five-lobed capsule, ending in an acute point, having five cells, each containing one roundish seed. It flowers in July and August, but unless the season proves warm, the seeds do not ripen in England.

The second sort grows naturally in Spain; this differs from the first in being smooth, the branches of this having no thorns; and the plant will live two years, whereas the first is annual.

The third sort was discovered by the late Dr. Shaw in Arabia; this is a low plant with a shrubby stalk, from which come out several weak branches armed with long thorns; the leaves of this are thick, narrow, and convex on their lower side; the flowers come out in the same manner as in the first sort.

These plants are propagated by seeds, which should be sown upon a border of fresh light earth, where the plants are designed to remain, for they do not bear transplanting well; when the plants come up, they may be thinned out to the distance of ten inches or a foot; and if they are kept clean from weeds, they will require no other care.

The first sort is an annual plant, which seldom perfects its seeds in England, unless the seasons prove very warm; therefore the best way is to sow the seeds upon a warm border in the autumn, and in frosty weather shelter the plants with mats, or some covering to secure them; or if they are sown in pots

F A G

pots and placed under a frame in the winter, and the following spring shaken out of the pots, and planted in a warm border, they will come early to flower, and thereby ripe seeds may be more certainly obtained.

The other two sorts may be treated in the same way; for as these seldom flower the first year from seeds, so the plants should be either kept in pots, and sheltered under a frame in winter, or placed in a warm border, where they may be sheltered with mats, or some other covering, to preserve them from the frost; and the following summer the second sort will flower and produce ripe seeds, but the third has not perfected any seeds as yet in England.

FAGOPYRUM. See **HELXINE**.

FAGUS. Tourn. Inst. R. H. 584. tab. 351. Lin. Gen. Plant. 951. [so called from *φάγω*, Gr. because supposed to be the food of the first race of mankind.] The Beech-tree; in French, *Hêtre*.

The **CHARACTERS** are,

It hath male and female flowers on the same tree; the male flowers are collected into globular beads; these have no petals, but have several stamina included in an empalement of one leaf; which are terminated by oblong summits. The female flowers have a one-leaved empalement cut into four parts, but have no petals; the germen is fixed to the empalement, supporting three styles, crowned by reflexed stigmas. The germen afterward becomes a roundish capsule, armed with soft spines, opening in three cells, each containing a triangular nut.

This genus of plants is ranged in the eighth section of Linnæus's twenty-first class, which includes those plants that have male and female flowers on the same plant, and the male flowers have many stamina. To this genus he has joined the Chestnut; but as the male flowers of the Chestnut are collected in long katkins, and those of the Beech are globular, and the fruit of the latter being triangular, there is sufficient reason for keeping them separate.

We know but one **SPECIES** of this genus, viz.

FAGUS (*Sylvatica*) foliis ovatis obsolete serratis. Hort. Cliff. 447. *Fagus*. Dod. Pempt. 832. *The Beech-tree with oval sawed leaves.*

There are some planters, who suppose there are two distinct species of this tree; one they call the Mountain Beech, which they say is a whiter wood than the other, which they distinguish by the title of Wild Beech; but it is certain, that this difference in the colour of the wood arises from the difference of the soils in which they grew, for I have not seen any specific difference in the trees. There have been seeds of a Beech-tree brought from North-America, by the title of Broad-leaved Beech, but the plants which were raised from them proved to be the common sort; so that we know of no other variety, excepting those with striped leaves, which is accidental; and when the trees are in vigour, the leaves become plain again.

This tree is propagated by sowing the mast; the season for which is any time from October to February, only observing to secure the seeds from vermin when early sowed; which, if carefully done, the sooner they are sown the better, after they are full ripe: a small spot of ground will be sufficient for raising a great number of these trees from seed, but you must be very careful to keep them clear from weeds; and if the plants come up very thick, you should not fail to draw out the strongest of them the autumn following, that those left may have room to grow; so that if you husband a seed-bed carefully, it will afford a three years draught of young plants, which should be planted in a nursery; and, if designed for timber trees, at three feet distance row from row, and eighteen inches asunder in the rows.

But if they are designed for hedges (to which the tree is very well adapted) the distance need not be so great; two feet row from row, and one foot in the rows will be sufficient. In this nursery they may remain two or three years, observing to clear them from

F E N

weeds, as also to dig up the ground between the rows, at least once a year, that their tender roots may the better extend themselves each way: but be careful not to cut or bruise their roots, which is injurious to all young trees; and never dig the ground in summer, when the earth is hot and dry; which, by letting in the rays of the sun to the roots, is often the destruction of young trees.

This tree will grow to a considerable stature, though the soil be stony and barren; as also upon the declivities of hills, and chalky mountains, where they will resist the winds better than most other trees; but then the nurseries for the young plants ought to be upon the same soil; for if they are raised in good soil and a warm exposure, and afterwards transplanted into a bleak barren situation, they seldom thrive, which holds true in most other trees; therefore I would advise the nursery to be made upon the same soil where the plantation is intended, but of this I shall say more under the article of **NURSERY**.

The tree is very proper to form large hedges to surround plantations, or large wilderness quarters; and may be kept in a regular figure, if sheared twice a year, especially if they shoot strong; in which case, if they are neglected but a season or two, it will be difficult to reduce them again. The shade of this tree is very injurious to most sorts of plants which grow near it, but is generally believed to be very salubrious to human bodies.

The timber is of great use to turners for making trenchers, dishes, trays, buckets; and likewise to the joiner for stools, bedsteads, coffins, &c. The mast is very good to fat swine and deer; it also affords a sweet oil, and the nuts have in scarce times supported some families with bread.

This tree delights in a chalky or stony ground, where it generally grows very fast; and the bark of the trees in such land is clear and smooth; and although the timber is not so valuable as that of many other trees, yet as it will thrive on such soils and in such situations where few better trees will scarce grow, the planting of them should be encouraged; especially as the trees afford an agreeable shade, and the leaves make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees: therefore in parks, and other plantations for pleasure, this tree deserves to be cultivated among those of the first class, especially where the soil is adapted to it.

The two sorts with variegated leaves may be propagated by budding or grafting them upon the common Beech, observing not to plant them in a good earth; which will cause the buds or cyons to shoot vigorously, whereby the leaves will become plain, which often happens to most variegated plants.

FARINA FOECUNDANS is the impregnating meal or dust on the apices or summits of flowers; which, being conveyed into the uterus or vasculum feminine of plants, fecundates the rudiments of the seeds in the ovary, which otherwise would decay and come to nothing. See **GENERATION OF PLANTS**.

FEATHERFEW, or **FEAVERFEW**. See **MATRICARIA**.

FENCES. In hotter climates than England, where they have not occasion for walls to ripen their fruit, their gardens lie open, where they can have water fence and prospects; or else they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleasing to the sight than a dead wall: but in colder countries, and in England, we are obliged to have walls to shelter and ripen our fruit, although they take away much from the pleasant prospect of the garden.

Since therefore we are under a necessity to have walls to secure our gardens from the injury of winds, as well as for the convenience of partitions or inclosures, and also to ripen our fruit, brick walls are accounted the warmest and best for this purpose: and these walls being built pannel-ways, with pillars at equal distances, will save a great deal of charge, in that the

the walls may be built thinner, than if they were built plain without these pannels, for then it would be necessary to build them thicker every where: and besides, these pannels make the walls look the handsomer.

Stone walls are by some preferred to those of brick, especially those of square hewn stones; but where they are designed for fruit, they should be faced with brick. Those that are made of rough stones, though they are very dry and warm, yet, by reason of their unevenness, are inconvenient to nail up trees to, except pieces of timber be laid in them here and there for to fasten a trellis to them.

But in large gardens it is better to have the prospect open to the pleasure-garden, which should be surrounded with a fosse, that from the garden the adjacent country may be viewed, but this must depend on the situation of the place; for if the prospect from the garden is not good, it had better be shut out from the sight by a wall, or any other fence, than to be open.

As also, where a garden lies near a populous town, and the adjoining grounds are open to the inhabitants, if the garden is open, there will be no walking there in good weather, without being exposed to the view of all passengers, which is very disagreeable.

Where these fosses are made round a garden which is situated in a park, they are extremely proper; because hereby the prospect of the park will be obtained in the garden, which renders these gardens much more agreeable than those which are confined.

In the making these fosses there have been many inventions; but, upon the whole, I have not seen any which are in all respects preferable to those which have an upright wall next the garden; which (where the soil will admit of a deep trench) should be six or seven feet high, so as to be above the reach of boys; and from the foot of this wall, the ground on the outside should rise with a gradual easy slope to the distance of eighteen or twenty feet; and where it can be allowed, if it slopes much farther, it will be easier and less perceptible as a ditch to the eye, when viewed at a distance. But if the ground is naturally wet, so as not to admit of a deep fosse, then, in order to make a fence against cattle, if the wall be four feet high, and slight posts of three feet and a half high are placed just behind the wall, with a small chain carried on from post to post, no cattle or deer will ever attempt to jump against it, therefore it will be a secure fence against them; and if these are painted of a dark lead colour, they will not be discerned at a distance; and at the same time the chain will secure persons walking in the garden from tumbling over: and if another chain is carried through the posts at one foot from the ground, it will more effectually prevent cattle from creeping under.

In such places where there are no good prospects to be obtained from a garden, it is common to make the inclosure of park-paling; which, if well performed, will last many years, and has a much better appearance than a wall: and this pale may be hid from the sight within, by plantations of shrubs and Evergreens; or there may be a quick hedge planted within the pale, which may be trained up, so as to be an excellent fence by the time the pales begin to decay.

There are some persons who make stuckade fences round their gardens to keep out cattle, &c. which, when well made, will answer the purpose of a fence; but this being very expensive in the making, and not of very long duration, has occasioned their not being more commonly in use.

As to fences round parks, they are generally of paling; which, if well made of winter-fallen Oak, will last many years; but a principal thing to be observed in making these pales, is not to make them too heavy; for when they are so, their own weight will cause them to decay; therefore the pale should be cleft thin, and the rails should be cut triangular, to prevent the wet lodging upon them; and the posts should be good, and not placed too far asunder, burning that part of them as goes into the ground. If these things are ob-

served, one of these pales will last, with a little care, upward of forty years very well. The common way of making these fences is, to have every other pale nine or ten inches above the intermediate ones; so that the fence may be six feet and a half high, which is enough for fallow deer; but where there are red deer, the fence should be one foot higher, otherwise they will leap over.

Some inclose their parks with brick walls; and in countries where stone is cheap, the walls are built with this material; some with, and others without mortar.

A kitchen-garden, if rightly contrived, will contain walling enough to afford a supply of such fruits as require the assistance of a wall for any family; and this garden being situated on one side, and quite out of sight of the house, may be surrounded with walls, which will screen the kitchen-garden from the sight of persons in the pleasure-garden; and being locked up, the fruit will be much better preserved than it can be in the public garden: and the having too great a quantity of walling is often the occasion that so many scandalous trees are frequently to be seen in large gardens, where there is not due care observed in their management.

And besides, the borders of pleasure-gardens are generally too narrow for the roots of fruit-trees, as will be shewn in its proper place, therefore it is in vain to plant them there.

The height of garden-walls should be from ten to twelve feet, which is a moderate proportion; and if the soil be good, it may in time be well furnished with bearing wood in every part, especially those parts planted with Pears, notwithstanding the branches being trained horizontally from the bottom of the walls.

I would recommend the White Thorn, the Holly, the Black Thorn and Crab, for outward fences to a good ground, but I do not approve of the intermixing them.

The White Thorn is the best quick to plant, because it is the most common, and may be clipped so as to render it the closest and hardiest fence of any other tree; and being very durable, is preferred to all others for outward fences, or for the division of fields, where they are exposed to cattle, &c.

The Black Thorn and Crab make very good fences, and are to be raised as the White Thorn; but if the kernels of Apples or Crabs be sown, it is best to sow the pommace with them, and they will come up the sooner, i. e. the first year, if sown in the autumn, soon after the fruit is ripe.

If Crab-stocks be planted while young, in the same manner as quick, they make excellent hedges soon, and so will some sorts of Plumbs, I mean such as have thorns.

The Black Thorn is not accounted so good for fences as the White Thorn, because it is apt to run more into the ground, and is not certain as to the growing, especially if the plants are not set very young; but then on the other hand, the bushes are by much the better, and are also more lasting than the White Thorn, or any other, for dead hedges, or to mend gaps; nor are they subject to be crept by cattle, as the others are. The richer the mould is, the better they will prosper, but yet they will grow on the same sort of soil that the White Thorn does.

The Holly will make an excellent fence, and is preferable to all the rest, but is a slow grower; but when once it does grow, it makes amends by its height, strength, and thickness.

It is raised of young seedling plants or berries, as the White Thorn is, and the berries will lie as long in the ground before they come up. It delights most in strong grounds, but will grow upon the driest gravel, amongst rocks and stones.

The berries lie till the second spring before they come up, therefore they should be prepared before they are sown (for this see the article *AGRICULTURE*.) It will be best to sow them in the place where you design they

they should grow, but they should be well weeded both before they come up and afterwards.

French Furz will also do well upon dry sandy banks, where few other plants will grow; but they must be kept very clean at the bottom, and cut thin, and never suffered to grow too high: nor should they be cut in dry weather, or late in autumn, nor early in the spring; the doing either of which is subject to make it die in patches, which is irrecoverable; nor will it ever break out again from old wood, if cut close in, after it has been suffered long to grow out.

Fences may likewise be made of Elder: if the soil be any thing good, you may put sticks of Elder, or truncheons ten or twelve feet long, slopeways in your banks, so as to make a chequer-work; and they will make a fence for a garden the quickest of any thing, and be a good shelter. But these fences are improper for a fine garden, because they shoot very irregular, and are ungovernable; as likewise the roots of these trees spread very far, and draw away all the heart of the ground, so as to starve whatever plants grow near them: and add to this the scattering of the berries, which will fill the ground near them with young plants; which, if not timely weeded out, will get the better of whatever grows near them; therefore this sort of fence is seldom planted, where a hedge of White Thorn can be had.

Elder planted on a bank, the side of which is washed with a river or stream, will make an extraordinary fence, and will preserve the bank from being undermined by the water, because it is continually sending suckers from the roots and lower branches, which is of great advantage where the stream washes away the bank. For middle fences in a garden, the Yew is the most useful, governable, and durable plant.

For surrounding wilderness quarters, Elm, Lime, Hornbeam and Beech, are very proper.

FENNEL. See FOENICULUM.

FENNEL-FLOWER. See NIGELLA.

FERRUM EQUINUM. See HIPPOCREPIS.

FERULA. Lin. Gen. Plant. 305. Tourn. Inst. R. H. 321. tab. 170. [takes its name of Ferendo, Lat. because the stalks of this plant are made use of in supporting the branches of trees; or of Feriendo, because in old time sticks were made of them, with which school-masters used to correct their scholars.] Fennel Giant; in French, *Ferule*.

The CHARACTERS are,

It hath an umbellated flower; the principal umbel is globular, and is composed of several smaller called rays, of the same form; the involucre is composed of several narrow leaves which fall off; the principal umbel is uniform. The flowers have five oblong erect petals which are equal, and five stamina of the same length, terminated by single summits; under the flower is situated a turbinate germen, supporting two reflexed styles, crowned by obtuse stigmas. The germen afterwards becomes an elliptical, compressed, plain fruit, dividing in two parts, each having a large elliptical plain seed, marked with three lines on each side.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, which contains those plants whose flowers have five stamina and two styles.

The SPECIES are,

1. FERULA (*Communis*) foliolis linearibus longissimis simplicibus. Hort. Cliff. 95. *Ferula with the smaller leaves, very narrow, long, and single.* Ferula major, seu fœmina Plinii. M. Umb. Pliny's Female Fennel Giant.
2. FERULA (*Galbanifera*) foliolis multipartitis, laciniis linearibus planis. Hort. Cliff. 95. *Ferula whose smaller leaves are divided into many narrow parts which are plain.* Ferula galbanifera. Lob. Obs. Galbanum-bearing Fennel Giant.
3. FERULA (*Tingitana*) foliolis laciniatis, lacinulis tridentatis inæqualibus. Hort. Cliff. 95. *Ferula whose smaller leaves are cut, and segments ending in three unequal parts.* Ferula Tingitana, folio latissimo lucido. H. Edin. Broad-leaved shining Fennel Giant from Tangier.

4. FERULA (*Ferulago*) foliis pinnatifidis, pinnis linearibus planis trifidis. Hort. Cliff. 95. *Ferula with wing-pointed leaves, whose pinnæ are narrow, plain, and trifid.* Ferula latiore folio. Mor. Hist. 3. p. 309. Fennel Giant with a broader leaf.

5. FERULA (*Orientalis*) foliorum pinnis basi nudis, foliolis setaceis. Hort. Cliff. 95. *Ferula with the wings of the leaves naked at the base, and the smaller leaves bristly.* Ferula Orientalis, Cachyros folio & facie. Tourn. Cor. 22. Eastern Fennel Giant with the leaf and appearance of Cachyros.

6. FERULA (*Meoides*) foliorum pinnis utrinque basi acutis, foliolis setaceis. Hort. Cliff. 95. *Ferula with the wings of the leaves pointed at their base on every side.* Laserpitium Orientale mei folio, flore luteo. Tourn. Cor. 23. Eastern Laserwort with a Spignel leaf and yellow flower.

7. FERULA (*Nodiflora*) foliolis appendiculatis, umbellis subsessilibus. Lin. Sp. Plant. 247. *Ferula with appendages to the smaller leaves, and umbels sitting close to the stalks.* Libanotis ferulæ folio & semine. C. B. P. 158. Libanotis with a Fennel Giant leaf and seed.

8. FERULA (*Glaucæ*) foliis supradecompositis, foliolis lanceolato-linearibus planis. Hort. Cliff. 95. *Fennel Giant with linear, spear-shaped, decomposed leaves.* Ferula folio glaucæ, semine lato oblongo. J. B. 3. p. 45.

The first of these plants is pretty common in the English gardens: this, if planted in a good soil, will grow to a great height, and divide into many branches: the lower leaves of this sort spread more than two feet every way, and branch out into many divisions, which are again subdivided into many smaller, garnished with very long, narrow, small leaves that are single; they are of a lucid green, and spread near the ground. From the center of the plant comes out the flower-stalk, which, when the plants are strong, will be near as large as a common broomstick, and will rise ten or twelve feet high, having many joints; if the stalks are cut, there issues from the vessels a foetid yellowish liquor, which will concrete on the surface of the wound. The stalks are terminated by large umbels of yellow flowers, which come out the latter end of June, or in the beginning of July; these are succeeded by oval compressed seeds, which have three lines running longitudinally on each side. These ripen in September, and the stalks decay soon after. When the stalks are dry, they are full of a light dry pith, which will soon take fire.

Mr. Ray says, that the people of Sicily use the pith of this plant for tinder to light their fires. And if this was practised by the ancients, we may easily guess why the poets feigned, that Prometheus stole fire from heaven, and carried it to the earth in a hollow Ferula.

The leaves of these plants decay soon after the seeds are formed, so that before they are ripe, there are seldom any leaves remaining, and the stalks afterward dry and become very tough; so it is not unlikely these may have been used for correction in the schools, as they are very light, and cannot do much injury. The roots of this sort will continue several years, especially on a dry soil, and will annually produce flowers and seeds.

The second sort doth not grow quite so large as the first, but the stalks of this will rise seven or eight feet high; the lower leaves are large, and greatly divided; the small leaves are flat, and not so long as those of the former, and are of a lucid green colour; the umbels of flowers are smaller, and the seeds are less. This flowers and ripens its seeds about the same time as the former sort.

The third sort hath large spreading leaves near the root, which are divided and subdivided into many parts; the small leaves of this are much broader than in any of the other sorts, and these are divided at their end into three unequal segments; the leaves are of a very lucid green. The stalks are strong, and rise to the height of eight or ten feet, and are terminated by large umbels of yellow flowers, which are

F E R

succeeded by large, oval, compressed seeds, like those of the first sort. This flowers and ripens its seeds about the same time as the former sort; it grows naturally in Spain and Barbary.

The fourth sort grows to much the same height as the second; the leaves of this branch out on every side pretty wide, and the smaller leaves on the divisions of the leaves, are broader than those of the others (excepting the third) but they are longer than those, and are of a darker green colour, ending in three points. The umbels of flowers are large, the flowers are yellow, and are succeeded by oval compressed seeds, like those of the other species. This grows naturally in Sicily.

The fifth sort is of much humbler growth than either of the former; the stalks of this seldom rise much more than three feet high; the lower leaves branch into many divisions, which are closely garnished with very fine bristly leaves; the umbel of flowers is but small, when compared with the others, and the seeds are smaller. It grows naturally in the Levant.

The sixth sort hath very branching leaves, the foot-stalks are angular and channelled; this sends out at every joint two side branches opposite; those toward the bottom are nine or ten inches long, and the others are diminished gradually to the top; these side branches send out smaller at each joint in the same manner, which are garnished with very fine leaves like those of Spignel, which stand quite round the stalks in shape of whorls; the flower-stalks grow three feet high, having a pretty large umbel of yellow flowers at the top; these are succeeded by oval flat seeds, which ripen in the autumn. It grows naturally in the Levant.

The seventh sort rises about three feet high; the leaves of this sort are much divided, and the small leaves on the divisions are very narrow and entire; the umbels of flowers are small, and are situated close to the stalks between the leaves at the joints; these are like those of the other sorts. It grows naturally in Istria and Carniola.

The eighth sort grows naturally in Italy and Sicily. The leaves of this are composed of many narrow flat segments, of a gray colour, and are divided into many parts: the stalk rises from three to four feet high, and is terminated by an umbel of yellow flowers in July, which are succeeded by oval compressed seeds which ripen in autumn.

All these sorts have perennial roots, which will continue several years; these have thick strong fibres, which run deep in the ground, and divide into many smaller, spreading to a considerable distance every way: the stalks are annual, and decay soon after they have perfected their seeds. As these plants spread very wide, so they should have each four or five feet room; nor should they stand near to other plants, for their roots will rob whatever plants grow near them of their nourishment.

They are all propagated by seeds, which should be sown in the autumn; for if they are kept out of the ground till the spring, they frequently fail, and those which succeed remain a year in the ground, so that much time is lost. The seeds may be sown in drills, by which method the ground may be easier kept clean; they must not be nearer than a foot row from row, and the seeds may be scattered two or three inches asunder in the drills; when the plants come up, they must be kept clean from weeds; and where they are too close together, they should be thinned, to allow them room to grow, for they will not be strong enough to remove till they have had two years growth; then in the autumn so soon as their leaves decay, the roots should be taken up with great care, so as not to cut or injure the tap or downright root, and then planted in the places where they are designed to remain, for after this transplanting they should not be removed. They delight in a soft, gentle, loamy soil, not too wet, and are very rarely injured by the hardest frost.

FERRARIA. Burman. Lin. Gen. 1018.

F I C

The CHARACTERS are,

It hath two keel-shaped spathe (or sheaths) which alternately inclose the flowers, which have six oblong pointed petals curled at their borders, revolvig, and are alternately larger; and three stamina sitting on the style, terminated by twin roundish summits; and a roundish three-cornered germen under the flower, supporting a simple erect stigma, crowned by three bifid, hooded, curled stigma; the germen afterward becomes an oblong three-cornered capsule, having three cells, filled with roundish seeds.

This genus of plants is ranged in the second section of Linnæus's twentieth class, intitled Gynandria triandria, the flower having three stamina which sit upon the style.

The SPECIES are,

1. **FERRARIA** (*Undulata*) foliis lanceolatis. Burm. Icon. *Ferraria with spear-shaped leaves.* Iris stellata, Cyclaminis radice, pullo flore. Barrel. Icon. 1216. *Starry Iris with a root like the Sowbread.*
2. **FERRARIA** (*Ensisformi*) foliis ensiformibus. Burm. Icon. *Ferraria with sword-shaped leaves.*

These plants grow naturally at the Cape of Good Hope; the roots of the first sort were sent me by Dr. Job Balter, of Zirkzee, who received them from the Cape. The root of this is shaped like that of the Bizantine Cornflag; it has a bright brown skin or cover; on the upper side is a hollow like a navel, from whence the flower-stalk arises. The stalk rises a foot and a half high, and is about the size of a man's middle finger, garnished with leaves the whole length; these are keel-shaped, embracing the stalks with their base. The upper part of the stalk divides into two or three branches, which are garnished with the same shaped leaves, but they are smaller; each of the branches are terminated by a large spathe or sheath of the same colour with the leaves, but this afterward withers and decays; these sheaths are double, and split at the top, where the flower peeps out its petals; these six petals are three alternately larger than the other, and are curiously fringed on their borders; they are of a pale greenish colour on their outside, but of a tawney purple within, and are of a short duration; in the centre of the flower is situated the style, having the three stamina fixed on the side, and is terminated by twin stigmas; the germen is situated under the flower, which afterward becomes an oblong smooth capsule with three cells, filled with roundish seeds.

The second sort is rare in England; this differs from the former in having smaller roots, and longer sword-shaped leaves, which have deeper veins; the stalk also does not divide so much, and the flowers are smaller, and less fringed on their borders.

They are both propagated by offsets sent out from the roots, in the same way as the Ixia, and should be cultivated in the same manner as is directed for those and the African Gladiolus, being too tender to thrive in the open air in England, nor do they succeed well in a green-house; therefore the best method is, to make a border four feet wide, either in the front of the green-house or stoves, covering it with a proper frame and glasses, so that the plants may enjoy the free air in mild weather, but be protected from frost. In such a frame, most of the African bulbous and tuberous rooted plants may be brought to great perfection.

There is a great singularity in the root of the first species, which is in its vegetating only every other year, and the intermediate years it remains at rest.

FICOIDES. See MESEMBRYANTHEMUM.

FICUS. Lin. Gen. Plant. 1032. Tourn. Inst. R. H. 662. tab. 420. The Fig-tree; in French, *Figuier*.

The CHARACTERS are,

It hath male and female flowers, which are included within the covering, or skin of the fruit, so do not appear unless the covering is opened; the male flowers are but few in number, and are situated in the upper part of the fruit; the female flowers are numerous, and situated in the lower part.

part. The male flowers sit each upon a separate foot-stalk, and have an empalement divided into three parts; they have no petals, but three bristly stamina as long as the empalement, terminated by twin summits; the female flowers sit upon distinct foot-stalks; their empalements are divided into five parts; they have no petals, but a germen as the empalement, supporting an inflexed style, crowned by two reflexed pointed stigmas. The germen afterward becomes a large seed, sitting in the empalement.

This genus of plants is ranged in the third section of Linnæus's twenty-third class, intitled Polygamia Polyœcia; the male and hermaphrodite flowers being situated in the same common covering, but in the wild Fig they are in distinct plants.

The SPECIES are,

1. *Ficus (Carica) foliis palmatis*. Hort. Cliff. 471. *Fig-tree with hand-shaped leaves*. *Ficus communis*. C. B. P. 457. *The common Fig-tree*.

11. *Ficus (Calyculata) foliis ovatis integerrimis obtusis, oppositis, fructu globoso calyculato*. *Fig-tree with oval, obtuse, entire leaves placed opposite, and a globular fruit having a calyx*. *Ficus folio lato subrotundo, fructu globoso, magnitudine nucis moschatæ*. Houft. MSS. *Fig-tree with broad roundish leaves, and a globular fruit about the bigness of a nutmeg*.

The first sort, which is the Fig whose fruit is va-

luable, is cultivated in most parts of Europe; of this there are great varieties in the warm countries, which have been obtained from seeds, therefore may be increased annually, if the inhabitants were careful in propagating the trees from the seeds of their best sorts. In England we had not more than four or five sorts till within a few years past; for as the generality of the English were not lovers of this fruit, so there were few who troubled themselves with the culture of it. But some years past I had a large collection of these trees sent me from Venice, by my honoured friend the Chevalier Rathgeb, which I planted and preserved to taste of their fruits, several of which proved excellent; these I have preserved and propagated, and those whose fruit were inferior have been neglected. And as the variety of them is very great, so I shall here mention only such of them as are the best worth cultivating, placing them in the order of their ripening.

1. The brown or Chestnut-coloured Ischia Fig. This is the largest fruit of any I have yet seen, it is short, globular, with a pretty large eye, pinched in near the foot-stalk, of a brown or Chestnut colour on the outside, and purple within; the grains are large, and the pulp sweet and high-flavoured; this sort very often bursts open when it ripens. It ripens the latter end of July, or the beginning of August. I have had this fruit ripen well on standards, in a warm soil. If this sort is planted against hot walls, two plentiful crops of fruit may be annually ripened.

2. The black Genoa Fig. This is a long fruit, which swells pretty large at the top where it is obtuse, but the lower part is very slender toward the stalk; the skin is of a dark purple colour, almost black, and hath a purple farina over it like that on some Plumbs; the inside is of a bright red, and the flesh is very high flavoured. It ripens early in August.

3. The small white early Fig. This hath a roundish fruit a little flatted at the crown, with a very short foot-stalk; the skin, when fully ripe, is of a pale yellowish white colour; the skin is thin, the inside white, and the flesh sweet, but not high-flavoured. This ripens in August.

4. The large white Genoa Fig. This is a large globular fruit, a little lengthened toward the stalk; the skin is thin, of a yellowish colour when fully ripe, and red within. This is a good fruit, but the trees are not good bearers.

5. The black Ischia Fig. This is a short fruit, of a middling size, a little flatted at the crown; the skin is almost black when ripe, and the inside is of a deep red; the flesh is very high flavoured, and the trees produce a good crop of fruit, but the birds are great devourers of them if they are not protected from them. This ripens in August.

6. The Malta Fig. This is a small brown fruit, much compressed at the top, and greatly pinched toward the foot-stalk; the skin is of a pale brown colour, as is also the inside; the flesh is very sweet, and well flavoured. If this sort is permitted to hang upon the trees till the fruit is shrivelled, it becomes a fine sweetmeat.

7. The Murrey, or brown Naples Fig. This is a pretty large globular fruit, of a light brown colour on the outside, with some faint marks of a dirty white, the inside is nearly of the same colour; the grains are pretty large, and the flesh is well flavoured. It ripens the latter end of August.

8. The green Ischia Fig. This is an oblong fruit, almost globular at the crown; the skin is thin, of a green colour, but when it is fully ripe, it is stained through by the pulp to a brownish cast; the inside is purple, and will stain linen, or paper; the flesh is high flavoured, especially in warm seasons. It ripens toward the end of August.

9. The Madonna Fig, commonly called here the Brunswick, or Hanover Fig, is a long pyramidal fruit of a large size; the skin is brown; the flesh is of a lighter brown colour, coarse, and hath little flavour. This ripens the end of August and the beginning of September;

September; the leaves of this sort are much more divided than of most other.

10. The common blue, or purple Fig is so well known, as to need no description.

11. The long brown Naples Fig. The leaves of this tree are deeply divided. The fruit is long, somewhat compressed at the crown. The foot-stalks are pretty long; the skin is of a dark brown when fully ripe, the flesh inclining to red; the grains are large, and the flesh well flavoured. It ripens in September.

12. The yellow Ischia Fig. This is a large fruit, of a pyramidal form; the skin is yellow when ripe, and the flesh is purple and well flavoured, but the trees do not produce much fruit here; they grow very luxuriant in branches, the leaves are very large, and not much divided. This ripens in September.

13. The small Brown Ischia Fig. This is a small pyramidal fruit with a very short foot-stalk; the skin is of a light brown, the flesh inclining to purple, of a very high flavour; it ripens late in September; the leaves of this tree are less divided than any of the other sorts. This is not a good bearer.

14. The Gentile Fig. This is a middle sized globular fruit; the skin, when ripe, is yellow; the flesh also inclines to the same colour; the grains are large, and the flesh is well flavoured, but it ripens very late, and the trees are bad bearers, so that it is not propagated much in England.

There are several other sorts which have been lately introduced from Italy, but all those which I have yet tasted, are inferior to those above-mentioned; some of them rarely ripen their fruit, and others are very ill bearers, not worth propagating, therefore I have omitted the mentioning of them here; for as those which are enumerated, continue in succession during the season for these fruits, and being preferable to the other, few persons will care to fill their gardens with a greater variety of these trees than are of real use, especially as they require good walls, and a very large share of room.

The first, second, third, ninth, and tenth sorts will ripen their fruits on standards, where they are in a warm situation; but the others require the assistance of walls exposed to good aspects, otherwise their fruit will not ripen in England.

Fig-trees generally thrive in all soils, and in every situation; but they produce a greater quantity of fruit upon a strong loamy soil, than on dry ground; for if the season proves dry in May and June, those trees which grow upon very warm dry ground, are very subject to cast their fruit; therefore, whenever this happens, such trees should be well watered and mulched, which will prevent the fruit from dropping off; and the fruit upon these trees are better flavoured, than any of those which grow upon cold moist land. I have always observed those Fig-trees to bear the greatest quantity of well-flavoured fruit, which were growing upon chalky land, where there has been a foot or more of a gentle loamy soil on the top. They also love a free open air; for although they will shoot and thrive very well in close places, yet they seldom produce any fruit in such situations; and all those which are planted in small gardens in London, will be well furnished with leaves, but I have never seen any fruit upon them which have grown to maturity.

These trees are always planted as standards in all warm countries, but in England they are generally planted against walls, there being but few standard Fig-trees at present in the English gardens; however, since some of the sorts are found to ripen their fruit well upon the standards, and the crop of Figs is often greater upon them, than upon those trees against walls, it is worthy of our care, to plant them either in standards or espaliers; the latter, I think, will succeed best in England, if they were managed as in Germany, where they untie the Fig-trees from the espalier, and lay them down, covering them in winter with straw or litter, which prevents their shoots being injured by the frost; and this covering is taken away gradually in the spring, and not wholly removed until all the

danger of frost is over, by which management they generally have a very great crop of Figs; whereas in England, where the trees grow against warm walls, if the spring proves warm, the young Figs are pushed out early, and the cold, which frequently returns in April and May, causes the greatest part of the fruit to drop off; so that our crop of Figs is generally more uncertain than most other sorts of fruit: and it frequently happens, that trees which are planted against north and east-aspected walls, produce a greater quantity of fruit in England, than those which are planted against south and south-east aspects; which must happen from the latter putting out their fruit so much earlier in the spring than the former; and if there happen cold frosty nights after the Figs are come out (which is frequently the case in this country) the forwardest of the Figs are generally so injured as to drop off from the trees soon after. In Italy, and the other warm countries, this first crop of Figs is little regarded, being few in number; for it is the second crop of Figs which are produced from the shoots of the same year, which is their principal crop, but these rarely ripen in England; nor are there above three or four sorts whichever ripen their second crop, let the summer prove ever so good, therefore it is the first crop which we must attend to in England; so that when these trees are growing against the best aspected walls, it will be a good method to loosen them from the wall in autumn; and after having divested the branches of all the latter fruit, to lay the branches down from the wall, fastening them together in small bundles, so that they may be tied to stakes, to keep them from lying upon the ground; the damp whereof, when covered in frosty weather, might cause them to grow mouldy, and hereby they will be secured from being broken by the wind. When they are thus managed in autumn, if the winter should prove very severe, the branches may be easily covered with Peas-haulm, straw, or any other light covering, which will guard the tender fruit-bearing branches from the injury of frost; and when the weather is mild, the covering must be removed, otherwise the Figs will come out too early; for the intention of this management is, to keep them as backward as possible: then in the spring, when the Figs are beginning to push out, the trees may be fastened up to the wall again. By this management I have seen very great crops of Figs produced in two or three places.

I have also seen great crops of Figs in some particular gardens, after very sharp winters, when they have, in general, failed in other places, by covering up the trees with Reeds made into pannels, and fixed up against the walls.

In the pruning of Fig-trees, the branches must never be shortened, because the fruit are all produced at the upper part of the shoots of the former year; if these are cut off, there can be no fruit expected, beside the branches are very apt to die after the knife; so that when the branches are too close together, the best way is to cut out all the naked branches quite to the bottom, leaving those which are best furnished with lateral branches at a proper distance from each other, which should not be nearer than a foot; and when they are well furnished with lateral branches, if they are laid four or five inches farther asunder, it will be better.

The best season for pruning of Fig-trees is in autumn, because at that time the branches are not so full of sap, and will not bleed so much, as when they are pruned in the spring; and at this season, the branches should be divested of all the autumnal Figs, and the sooner this is done, when the leaves begin to fall off, the better will the young shoots resist the cold of the winter. There are some seasons so cold and moist, that the young shoots of the Fig-trees will not harden, but are soft, and full of juice; when this happens, there is little hope of a crop of Figs the succeeding year, for the first frost in autumn will kill the upper part of these shoots, for a considerable length downward; whenever this happens, it is the best way to cut off all the decayed part of the shoots, which will prevent

prevent the infection from destroying all the lower part of the branches; and, by this method, I have seen a moderate crop of Figs put out from the lower part of the shoots; where, if the shoots had not been injured, there would have been no fruit produced, because it is chiefly from the four or five uppermost joints of the shoots that the fruit comes out; and it is for this reason, that as many of the short lateral branches should be preserved as possible, those being the most productive of fruit; for where the long strait shoots are fastened up, there will be no fruit, but at their extremities, so that all the lower part of the trees will be naked, if there is not a particular regard had to supply young shoots in every part of the trees.

Those trees which are laid down from the espaliers, should not be fastened up again till the end of March, for the reasons before given, and those against walls may remain some time longer; and when the large shoots of these are nailed up, if the small lateral branches are thrust behind these, to keep them close to the wall, it will secure the young Figs from being injured by the morning frosts; and when this danger is over, they may be brought forward to their natural position again: during the summer season these trees will require no other pruning, but to stop the shoots in the spring, where lateral branches are wanting; and as the branches are often blown down by wind, therefore, whenever this happens, they should be immediately fastened up again, otherwise they will be in danger of breaking; for the leaves of these trees being very large and stiff, the wind has great power on them; so that where the branches are not well secured, they are frequently torn down.

Those trees which are planted against espaliers may be protected from the injury of frost in the spring, by placing Reeds on each side the espalier, which may be taken down every day, and put up again at night; but this need not be practised in warm weather, but only at such times as there are cold winds and frosty mornings; and although there is some trouble and expence attending this management, yet the plentiful crop of Figs which may this way be obtained, will sufficiently recompense for both: the best way of making this covering is, to fasten the Reeds with rope yarn in such a manner as that it may be rolled up like a mat, that the whole may with great facility be put up or taken down; and if these Reeds are carefully rolled up, after the season for using them is over, and put up in a dry shed, they will last several years.

There are several persons who of late have planted Fig-trees in standards, which have succeeded very well; this practice was revived, by observing some old standard Fig-trees in some gardens, which had been growing many years, and generally produced a much greater plenty of fruit than any of those trees which were growing against warm walls; indeed, these standard Fig-trees are in much greater danger of having their branches killed by severe frost, but in mild winters they generally do better than those against walls; so that where these trees can be covered in very hard winters, there will always be plenty of fruit; and these may be covered by fastening as many of the branches together as can be conveniently brought into a bundle, and winding some Hay-bands, Straw, Peas-haulm, or any such light covering as can be readily procured, which in the spring may be gradually taken off, so as not to expose the shoots all at once to the open air; and if there is some such light covering laid round the stems, and upon the surface of the ground about their roots, it will more effectually secure them from the danger of frost; but when this is practised, great care should be taken that no mice or rats harbour in this covering, for these will eat off the bark from their shoots, and kill them: and I have often observed those trees which were against walls, have suffered greatly by these vermin, by having many of their largest branches disbarked near the ground, which has absolutely killed them; and it is in the winter that these vermin do this mischief to

them, therefore they should be carefully watched at that season.

The common blue and white Figs, which are the sorts which have been the most generally cultivated in England, are not so proper to plant for standards, as some other sorts which have been lately introduced; for they are much tenderer, and are often killed almost to the root, when some of the other sorts, which have been growing in the same situation, have received very little injury from the frost; indeed the white sort is generally a great bearer, and the fruit is very sweet; but to those palates which are accustomed to Figs, that sort is not much in esteem, from its want of flavour: those which have succeeded best with me, are the first and third sorts. Their branches are rarely hurt by frost in winter, and their fruit will always ripen well; for in favourable seasons, many of these sorts, which were growing against walls, have ripened their second crop of fruit tolerably well. I have also planted many of these sorts of Fig-trees against north-east and north-west aspects; some of those which were first planted, have produced a good quantity of well tasted fruit, but were ripe much later, which has encouraged me to plant many more of these trees to the same aspects, and also to increase my number of standard trees.

I am aware, that what I have here advanced, in relation to the pruning and dressing of Fig-trees, will be condemned by great numbers of people, who will not give themselves time to consider and examine the reasons upon which I have founded this practice, nor to make one single experiment to try the truth of it, as being vastly different from the general practice of most gardeners, who always imagine, that Fig-trees should never have much pruning; or, at least, that they should always be suffered to grow very rude from the wall, to some distance. That by this management I have often seen great quantities of fruit I cannot deny, but then this has been only after mild winters; for it is very certain, that in sharp frosts few of these outside shoots escape being greatly injured where they are not covered; whereas it rarely happens that those shoots which are closely nailed to the wall in autumn, or laid down and covered, suffer the least damage; and the fruits are always produced a fortnight sooner upon these branches, than they are upon those which grow from the wall: but although the trees which are suffered to grow rude from the walls may produce a good quantity of fruit for a year or two, yet afterward the trees will only bear at the ends of the shoots, which will then be so far from the wall, as to receive little benefit from it; nor can the trees be reduced again to any regularity, without cutting away the greatest number of their branches, by which a year or two will be lost before they will come to bear again.

The season also for pruning, which I have laid down, being vastly different from the common practice and opinion of most gardeners, will also be objected against; but I am sure, if any one will but make trial of it, I doubt not his experience will confirm what I have here advanced; for as one great injury to this tree proceeds from the too great effusion of sap at the wounded parts, by this autumn pruning this is prevented; for, at that season, all the parts of European trees which cast their leaves, are less replete with moisture than at any other time of the year; for by the long continuance of the summer's heat, the juices of plants having been exhausted in the nourishment and augmentation of wood, leaves, fruits, &c. and also great quantities being evaporated by perspiration, the root not being able to send up a supply equivalent to this great consumption, the branches must contain a much less quantity of sap than in the spring, when it has had several months supply from the root; which, though but small in proportion to what is sent up when the heat is greater, yet there being little or no waste, either by perspiration or augmentation, there must be a greater quantity contained in the branches; which also is easily to be observed, by breaking or cutting off a vigorous branch of a Fig-tree at both seasons (the sap, being milky, may be readily discerned) when that cut in au-

turn shall be found to stop its bleeding in one day's time, or less; whereas that cut in the spring will often flow a week or more, and the wound will be proportionably longer before it heals.

Of late years there has been some of these trees planted against fire-walls, which have succeeded very well where they have been properly managed; but where they have been kept too close, and drawn by glasses, they have not produced much fruit; therefore whenever this is practised, the heat should not be too great, nor the glasses, or other covering, kept too close, but at all times, when the weather is favourable; a good share of free air should be admitted; and if the trees are young, that their roots are not extended beyond the reach of the covering, they must be frequently watered when they begin to shew fruit, otherwise it will drop off; but old trees, whose roots are extended to a great distance, will only require to have their branches now and then sprinkled over with water. If these trees are properly managed, the first crop of fruit will be greater than upon those which are exposed to the open air, and will ripen six weeks or two months earlier, and a plentiful second crop may also be obtained, which will ripen early in September, and sometimes in August, which is about the season of their ripening in the warmer parts of Europe; but the fires should not be used to these trees till the beginning of February; because when they are forced too early, the weather is frequently too cold to admit a sufficient quantity of fresh air to set the fruit; but the covers should be put over the trees a month before, to prevent the shoots from being injured by the frost.

It may not be improper in this place to mention the great pains which the inhabitants of the Levant are at in the culture of their Figs; and without which (it is generally said by all the travellers who have written on this subject, as also by Pliny, and other old naturalists) their fruit will fall off, and be good for nothing. I shall here set it down, as I find it in the travels of Mons. Tournefort, chief botanist to the late king of France.

“ Pliny, says he, observed, That in Zia they used to dress the Fig-trees with much care; they still continue to do so. To understand aright this husbandry of Figs (called in Latin, *Caprificatio*) we are to observe, that in most of the islands of the Archipelago, they have two sorts of Fig-trees to manage; the first is called *Ornos*, from the old Greek, *Erinos*, a wild Fig-tree; or *Caprificus*, in Latin; the second is the domestic, or garden Fig-tree; the wild sort bears three kinds of fruit, *Fornites*, *Cratitres*, and *Orni*, of absolute necessity towards ripening those of the garden Fig.

“ The *Fornites* appear in August, and continue to November, without ripening; in these breed small worms, which turn to a sort of gnats, no where to be seen but about these trees. In October and November these gnats of themselves make a puncture into the second fruit, which is called *Cratitres*, and do not shew themselves till towards the end of September; and the *Fornites* gradually fall away after the gnats are gone; the *Cratitres*, on the contrary, remain on the tree till May, and inclose the eggs, deposited by the *Fornites*, when they pricked them. In May the third sort of fruit begins to put forth from the same wild Fig-trees which produced the other two; this is much bigger, and is called *Orni*; when it grows to a certain size, and its bud begins to open, it is pricked in that part by the gnats of the *Cratitres*, which are strong enough to go from one fruit to the other, to discharge their eggs.

“ It sometimes happens, that the gnats of the *Cratitres* are slow to come forth in certain parts, while the *Orni* in those very parts are disposed to receive them; in which case the husbandman is obliged to look for the *Cratitres* in another part, and fix them at the end of the branches of those Fig-trees, whose *Orni* are in fit disposition to be pricked by the gnats;

“ if they miss the opportunity the *Orni* fall, and the gnats of the *Cratitres* fly away. None but those that are well acquainted with this sort of culture, know the critical minutes of doing this; and in order to it, their eye is perpetually fixed on the bud of the Fig; for that part not only indicates the time that the prickers are to issue forth, but also when the Fig is to be successfully pricked; if the bud be too hard, and too compact, the gnat cannot lay its eggs, and the Fig drops when this bud is too open.

“ These three sorts of fruit are not good to eat; their office is to help to ripen the fruit of the garden Fig-trees, in manner following: during the months of June and July, the peasants take the *Orni* at a time that their gnats are ready to break out, and carry them to the garden Fig-trees; if they do not nick the moment, the *Orni* fall, and the fruit of the domestic or garden Fig-tree not ripening, will, in a very little time, fall in like manner. The peasants are so well acquainted with these precious moments, that every morning, in making their inspection, they only transfer to their garden Fig-trees such *Orni* as are well conditioned, otherwise they lose their crop. It is true, they have one remedy, though an indifferent one, which is, to strew over the garden Fig-trees the *Ascolimbros*, a very common plant there, and in whose fruit there is a sort of gnats proper for pricking; perhaps they are the gnats of the *Orni*, which are used to hover about and plunder the flowers of this plant.

“ To sum up all in one word, The peasants so well order the *Orni*, that their gnats cause the fruit of the garden Fig-tree to ripen in the compass of forty days. These Figs are very good green; when they would dry them, they lay them in the sun for some time, then put them in an oven to keep them the rest of the year. Barley bread and dried figs are the principal subsistence of the boors and monks of the Archipelago; but these Figs are very far from being so good as those dried in Provence, Italy, and Spain; the heat of the oven destroys all their delicacy and good taste; but then, on the other hand, this heat kills the eggs which the prickers of the *Orni* discharged therein, which eggs would infallibly produce small worms that would prejudice these fruits.

“ What an expence of time and pains is here for a Fig, and that but an indifferent one at last! I could not sufficiently admire the patience of the Greeks, busied above two months in carrying these prickers from one tree to another. I was soon told the reason, one of their Fig-trees usually produces between two and three hundred pounds of Figs, and ours in Provence seldom above twenty-five.

“ The prickers contribute, perhaps, to the maturity of the fruit of the garden Fig-tree, by causing them to extravasate the nutritious juice, whose vessels they tear asunder in depositing their eggs; perhaps too, besides their eggs, they leave behind them some sort of liquor proper to ferment gently with the milk of the Fig, and to make their flesh tender. Our Figs in Provence, and even at Paris, ripen much sooner for having their buds pricked with a Straw dipped in olive oil. Plumbs and Pears, pricked by some insects likewise ripen much the faster for it; and the flesh round such puncture is better tasted than the rest. It is not to be disputed but that considerable change happens to the contexture of fruits so pricked, just the same as to parts of animals pierced with any sharp instrument.

“ It is scarce possible well to understand the antient authors who have treated of caprification (or husbanding and dressing the wild Fig-tree) if one is not well apprised of the circumstances, the particulars whereof were confirmed to us not only at Zia, Tinos, Mycone, and Scio, but in most of the other islands.”

Fig-trees are propagated in England, either by the suckers, which are sent out from their roots, and by layers made, by laying down of their branches, which in one year will put out roots sufficient to be removed, or by planting of cuttings, which, if properly managed, will take root; the first of these is a bad method, because all those trees which are raised from suckers, are very subject to send out great quantities of suckers again from their roots; and the branches of the suckers are not so compact, as those of the layers, but are fuller of sap, so in greater danger of being injured by the frost; those plants which are propagated by layers, are the best, provided the layers are made from the branches of fruitful trees; for those which are made from the suckers, or shoots, produced from old stools, are very soft, and full of sap, so are in danger of suffering by the frost, and these will shoot greatly into wood, but will not be very fruitful; for, when trees have acquired a vicious habit while young, it is seldom they are ever brought to be fruitful afterward; therefore the shoots which are laid down, should be such as are woody, compact, and well ripened, not young shoots, full of sap, whose vessels are large and open. The best time for laying down of the branches is in autumn; and if the winter should prove very severe, if they are covered with some old tan, or any other mulch, to keep the frost from penetrating the ground, it will be of great service to them; by the autumn following, these will be sufficiently rooted for removing, when they should be cut off from the old plants, because at that season the branches are not so full of sap as in the spring, so will not bleed so much as when cut off in the spring. If the place is ready to receive them, the layers should be transplanted in autumn, where they are to remain; but if it is not, then the layers may remain till the spring, provided they are separated from the old plants in autumn. As these plants do not bear transplanting well when they are large, it is the better way to plant them at first in places where they are to remain; and after they are planted, the surface of the ground about their roots should be covered with mulch to keep out the frost; and if the winter should prove very severe, it will be proper to cover the branches with Reeds, Peas-haulm, Straw, or some other light covering, which will prevent their tender ends being killed by the frost, which frequently happens where this care is wanting.

The other method of propagating these trees, is by cuttings, which should be taken from the trees in autumn, for the reason before given: these must be chosen from such branches as are compact, whose joints are near each other; and they should have a part of the former year's wood at their bottom, and the top of each should be left entire, not shortened as is usually practised with other cuttings; then they should be planted eight or nine inches deep, in a bed of loamy earth, in a warm situation, covering the surface of the ground, three or four inches thick, with old tanner's bark, to keep out the frost; and in severe frost their tops should be covered with Straw, Peas-haulm, Fern, or other light covering, to protect them from frost, which should be removed in the spring; but the tan may remain, for that will prevent the drying winds of the spring, and the sun in summer, from penetrating the ground, and will be of great use to secure the cuttings from injury; these cuttings will be rooted sufficiently by the following autumn, when they should be transplanted, and treated in the same manner as the layers.

If fruitful branches of these trees are cut off, and planted in pots, or tubs, filled with good earth, and these are plunged into a good hot-bed of tanners bark in the stove, they will put out fruit early in the spring, which will ripen in the middle of May.

We shall now return to the other sorts of Figs, which grow naturally in warm countries, but are preserved in the gardens of those who are curious in collecting rare exotic plants, for these do not bear eatable fruit in their native soil; but their leaves being large and

beautiful, the plants make a pleasing variety in the stove.

The second sort grows naturally in the Levant, where it becomes a large tree, dividing into many branches, which are garnished with leaves shaped like those of the Mulberry, and affords a friendly shade in those hot countries. The fruit is produced from the trunk and larger branches of the tree, and not on the smaller shoots, as in most other trees; the shape is like the common Fig, but is little esteemed. This is called the Sycamore, or Pharaoh's Fig-tree.

The third sort grows naturally in India, where it is sacred, so that none dare destroy them; it is called by some the Indian God-tree; this rises with a woody stem to a great height, sending out many slender branches, which are garnished with smooth heart-shaped leaves, ending in a long tail, or point; they are entire, smooth, and of a light green, having pretty long foot-stalks; they are between six and seven inches long, and three inches and a half broad toward their base, diminishing gradually to the top, where they run out in a narrow point, an inch and a half long. The fruit comes out on the branches, which are small, round, and of no value.

The fourth sort rises with many stalks, which grow to the height of thirty or forty feet, dividing into a great number of branches, which send out roots from their under branches, many of which reach to the ground; so that in such places where the trees grow naturally, their roots and branches are so interwoven with each other, as to render the places impassable. In India, the Banyans trail the branches of these trees into regular archades, and set up their pagods under them, these being the places of their devotion. In America, where these trees are equally plenty, they form such thickets, as neither man nor beast can pass through. The leaves of this sort are of a thick substance, smooth, and oval; they are six inches long, and four inches broad, with obtuse ends. The fruit is the size of a marble, and round, but of no use.

The fifth sort grows naturally in both Indies; this rises with a woody stalk to the height of thirty feet, sending out many branches, which are garnished with oblong leaves standing upon pretty long foot-stalks; they are about six or eight inches long, and two inches and a half broad, ending in an obtuse point, of a dark green, and smooth on their upper side, but of a light green, and veined on their under side. The fruit is small, and of no value. The branches of these trees send out roots from their lower side, which sometimes reach the ground.

The sixth sort grows naturally in the West-Indies, where it rises to the height of thirty or forty feet, sending out many slender branches, which put out roots in the same manner as the former. The leaves of this are eight or nine inches long, and two inches broad, ending in points. The fruit is small, round, and of a blood colour when ripe, but is not eatable.

The seventh sort grows naturally in India, where it rises to the height of twenty-five feet, and divides into many branches, which are garnished with oval-pointed leaves, which are smooth, and of a lucid green. The fruit is small, and grows in clusters from the side of the branches; these are not eatable.

The eighth sort grows naturally in India; this is a low trailing shrub, whose stalks put out roots at their joints, which strike into the ground, so is propagated plentifully where it naturally grows. The leaves are two inches and a half long, and near two inches broad, ending in points; they are of a lucid green, and are placed without order on the branches; the fruit is small, and not eatable.

The ninth sort rises with a strong, upright, woody stalk twenty feet high, sending out several side branches, which are garnished with large, oval, stiff leaves, about fourteen inches long, and near a foot broad, and are rounded at the ends; they have several transverse veins, which run from the midrib to the sides. The foot-stalks are long, and frequently turned next to the branches; the upper side of the leaves

leaves are of a lucid green, and the under side is of a gray, or sea-green colour, they are of a thick substance, and very smooth; this grows naturally in India, from whence it was brought to the gardens in Holland.

The tenth sort grows naturally in the West-Indies, where it rises twenty feet high, sending out many side branches, which are covered with a white bark, and garnished with oblong heart-shaped leaves, ending in acute points; they are about three inches long, and one inch and a half broad, near the base; of a lucid green on their upper side, but of a pale green on their under, standing upon very long foot-stalks. The fruit comes out from the side of the branches, toward their ends; they are about the size of large gray Peas, and of a deep purple colour, sitting close to the branches; these are not eatable.

The eleventh sort grows naturally at La Vera Cruz, from whence it was sent me by the late Dr. Houstoun; this rises with many shrubby stalks to the height of twelve or fourteen feet, and divides into many smaller branches, which are garnished with oval stiff leaves, which are obtuse; they are four inches long, and three broad, of a light green, and stand upon very short foot-stalks, which are joined to a cup, in which the fruit sits; this is globular, and the size of a middling nutmeg, of a deep yellow, when ripe, but is not eatable.

The second sort, I believe, is not in England at present; I raised two or three of these plants from seeds in the year 1736, which were destroyed by the severe frost in 1740, since which time I have not been able to procure any of the seeds. The other sorts are preserved in several curious gardens; they are easily propagated by cuttings during the summer season. When the cuttings are taken from the plants, they should be laid in a dry shady place for two or three days, that the wounds may be healed over, otherwise they are apt to rot; for all these plants abound with a milky juice, which flows out whenever they are wounded; for which reason, the cuttings should have their wounded part healed over and hardened before they are planted; after which they should be planted in pots filled with sandy light earth, and plunged into a moderate hot-bed, where they should be shaded from the sun, and two or three times a week gently refreshed with water, if the season is warm; but they must not have too much moisture, for that will infallibly destroy them. When the cuttings have taken root sufficient to transplant, they should be each planted into a separate small pot filled with light undunged earth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root; then they should have a large share of free air admitted to them at all times when the weather is favourable, to prevent their drawing up weak, and to give them strength before the cold comes on. In autumn the pots should be removed into the stove, and plunged into the tan-bed, where they should constantly remain, and must be treated in the same manner as other tender plants from the same countries; for although two or three of the sorts may be treated in a hardier manner, yet they will not make much progress.

FICUS INDICA. See **OPUNTIA**.

FILAGO. There are several species of this genus, some of which grow naturally upon barren land in most parts of England. They are called by some Cottonweed, by others Cudweed, their leaves being white, and, when broken, have cottony threads. These have been ranged under the genus of *Gnaphalium* by most botanists, and one of the species which is used in medicine, stands in the list of simples by that appellation. As these plants are not cultivated in gardens, I shall not trouble the reader with a farther account of them.

FILBERT. See **CORYLUS**.

FILIPENDULA. See **SPIRÆA**.

FILIUS ANTE PATREM [i. e. the son before the father] an expression which botanists apply to plants, whose flower comes out before their leaves,

or those plants which send forth side branches of flowers, which advance above the middle.

FILIX, Fern. There are great varieties of this plant in the different parts of the world, but particularly in America, as may be seen in the Natural History of Jamaica, published by Sir Hans Sloane, Bart. and in Plumier's American Ferns: but as they are plants which are seldom propagated in gardens, I shall pass them over in this place.

FILM, that woody skin which separates the seeds in the pods of plants.

FIMBRIATED [of *Fimbria*, *Lat.* a fringe] a term relating to the leaves of plants when they are jagged on the edges, having, as it were, a fringe about them; these are often called furbelowed leaves.

FIRE. However foreign, at the first view, this article may seem to our present purpose, yet I am of opinion, that a tolerable acquaintance with its nature, as far as it can be attained, and its effects, will contribute no small assistance in forwarding the work of vegetation. And though the theory of fire is indeed philosophical, yet the consideration of its effects, and how it operates on vegetables, will be of no small use in the culture of them.

That which best defines and distinguishes fire from every thing else, is its heating; and so it may be defined, Whatsoever warms or heats bodies.

Heat is something, the presence of which is best perceived by the dilatation of the air or spirit in the thermometer. So then, fire is a body, and a body in motion too. The motion of it is proved by its expanding the air, and that it is a body by experiment. Pure mercury, being inclosed in a phial with a long neck, and kept in a gentle heat for the space of a year, will be reduced into a solid, and the weight also will be increased considerably; which increase cannot proceed from any thing else but the accession of fire.

The nature of fire is so obscure and wonderful, that it was held by many of the ancients as a deity; and several authors of prime note have taken great pains to discover the mystery of it, without having been able to explain many of the principal effects thereof. The learned Herman Boerhaave has used no less industry in making a new set of experiments, in order to come to a clearer knowledge of them; and having laid down a new doctrine of fire, in a course of public lectures, I shall briefly take notice of such of them as I apprehend may be of use.

"Fire (says he) in effect, appears to be the general instrument of all the motion in the universe. The constant tenor of a great number of experiments leaves no room to doubt, but that, if there were no fire, all things would instantly become fixed and immoveable. Of this there are instances every winter; for while frost prevails, the water, which before was fluid, by a mere privation of heat, becomes solid, i. e. hardens into ice, and so remains till dissolved again by fire. Thus, were a man entirely destitute of heat, he would immediately freeze into a statue; and thus the air itself, which is found in continual motion, being always either expanding or condensing, would, upon the absence of fire, contract itself, and cohere into a firm rigid mass; so also animals and vegetables, all oils, salts, &c. would, upon the like occasion, immediately congeal."

Although this doctrine of fire, here laid down by Boerhaave, seems new and extraordinary, at least to those who have been used to consider fire in the light that it has been set in by the Lord Bacon, Mr. Boyle, and Sir Isaac Newton; and though we ought to pay great veneration to those illustrious authors, yet, in the judgment of themselves, we should be in excusable, if we should absolutely acquiesce in what they have done, and shut the door against farther and better information.

It may reasonably be supposed, that Dr. Boerhaave has had an opportunity of going beyond them; in that, besides all the experiments and observations that they have

have had to build upon, he has had the advantage of a new set, which they were unacquainted with.

As to the nature of fire, the great and fundamental difference is, whether it be originally such, formed thus by the great Creator himself, at the beginning of things? or, whether it be mechanically producible from other bodies, by inducing some alteration in the particles of it?

Among the modern writers, Homberg, Boerhaave, the younger Lemery, and Dr. Gravesande, maintain the former, and the English authors chiefly maintain the latter.

Mons. Homberg holds, That the chymical principle or element, sulphur, which is supposed one of the simple, primary, pre-existent ingredients of all natural bodies, is real fire; and, of consequence, fire is coeval with all bodies. *Essai de Souffre Principe*, Mem. de l'Academie, anno 1705.

Dr. Gravesande proceeds much on the same principle: according to him, fire enters the composition of all bodies, is contained in all bodies, and may be separated or procured from all bodies, by rubbing them against each other, and thus putting their fire in motion: and he adds, That fire is by no means generated by such motion. *Elem. Phys. Tom. II. cap. 1.*

Mr. Lemery the younger, asserts the absolute and ingenerable nature of fire, and also extends it farther; not contented to confine it, as an element, to bodies, he endeavours to shew, that it is "Equally diffused through all space; is present in all places; in the void space between bodies, as well as the insensible interstices between their parts." Mem. de l'Acad. anno 1713.

This last sentiment falls in with that of Boerhaave. Of the contrary opinion is the Lord Bacon, who, in his treatise de Forma Calidi, deduces from a great number of particulars, that heat in bodies is no other than motion, only a motion so and so circumstantiated; so that to produce heat in a body, nothing is required but to excite such motion in the parts of it. His opinion is seconded by Mr. Boyle, in his treatise of the Mechanical Origin of Heat and Cold; where he maintains the same doctrine, with new observations and experiments, of which two are as follow:

He says, "In the production of heat there appears nothing on the part either of the agent or patient but motion, and its natural effects. When a smith briskly hammers a small piece of iron, the metal thereby becomes exceedingly hot; yet there is nothing to make it so, except the forcible motion of the hammer, impressing a vehement and variously determined agitation on the small parts of the iron; which, being a cold body before, becomes by that superinduced commotion of its small parts hot; first, in a more loose acceptation of the word, with regard to some other bodies, compared with which it was cold before; then sensibly hot, because this agitation sensibly surpasses that of the parts of our fingers. And in this instance oftentimes the hammer and anvil continue cold after the operation; which shews, that the heat acquired by the iron was not communicated by either of these implements, as heat, but produced in it, by a motion great enough strongly to agitate the parts of so small a body as the piece of iron, without being able to have the like effect upon so much greater masses of metal as the hammer and anvil; though if the percussions were often and briskly renewed, and the hammer were small, this also might be heated; whence it is not necessary, that a body itself should be hot to give heat.

"If a large nail be driven by a hammer into a plank of wood, it will receive several strokes on its head, ere it grows hot; but when it is once driven to the head, a few strokes suffice to give it a considerable heat; for while at every blow with the hammer the nail enters farther into the wood, the motion produced is chiefly progressive, and is of the whole nail tending one way; but, when the motion ceases, the impulse given by the stroke being

"unable to drive the nail farther on or break it, must be spent in making a various, vehement, and intestine commotion of the parts among themselves, wherein the nature of heat consists."

That fire is the real cause of all the changes in nature, will appear from the following consideration.

All bodies are either solid or fluid; the solid of themselves are either commonly supposed to be inactive or motionless; the fluid both move and are moved.

And all solids are found to be so much the more firm and contracted, as they have the less fire in them. This is evident in iron, which, when heated, expands itself into a much greater space than when it was cold; so that any solid and hard body, by being freed from all fire, would sink into a much less bulk, and its parts would cohere more nearly, and with greater force than before.

As to fluids, they all harden, so as to be visible to the eye upon the absence of fire; as water, by the cold of a severe winter, will form itself into a solid globe, and yet even then contains a great deal of fire, as appears evidently upon applying a thermometer to it, which is capable of falling twenty divisions lower before it arrive at the point of the most intense cold: and hence it is, that the spirit of wine is kept from freezing in the thermometer, which would undergo the common fate of other things, were there not abundantly more fire in it.

The air itself expands by a greater quantity of fire, and condenses by a less; but it still contains a large quantity of fire, where it is most of all contracted; this is evident from the striking of a flint against a steel, which is followed by sparks of fire.

Likewise if this fire could be taken from the air, it would become solid and perfectly at rest, and, by consequence, incapable of change.

"Fire (says Dr. Gravesande, in *Element. Phys.*) naturally unites itself with bodies; and hence it is, that a body brought near to the fire grows hot, in which case it also expands or swells; which expansion is not only observed in very solid bodies, but in those whose parts do not cohere; in which case they likewise acquire a great degree of elasticity, as is observed in air and vapours."

Fire being thus acknowledged the instrumental cause of all motion, it remains that itself be moved; nay, to move, must be more natural and immediate to fire, than to any other body; and hence some have ventured to make motion essential to fire: but as this is inconsistent with the notion of matter, which is defined to be inert and passive, and as fire is capable of being proved material, we ought rather to agree, that the motion of fire itself is derived from some higher and metaphysical cause. A property of perpetual mobility may indeed be superadded to the other properties of fire, but it has no natural necessary connexion with them; nor can it be maintained with them otherwise than by some extrinsic efficacy of a superior cause.

However, that it is by motion that fire produces its effects, is evident; and hence the action of fire cannot make any alteration in the elementary substance of bodies; for it is necessary, that what acts upon an object, be without that object, i. e. the fire must not penetrate the elementary parts, but only enter the pores and interstices of bodies; so that it does not seem capable of making those transmutations, which Sir Isaac Newton ascribes to it.

In effect, as to all our purposes, it may perhaps be said, that fire is always in motion. For instance, take six several sorts of thermometers, and two vessels of water with sal armoniac mixed therein, and apply the thermometers to it; and the consequence will be, that the air being condensed in them, the spirit will descend in all of them: remove the vessels of water, and the air growing warmer, and rarefying, the spirit will ascend again; so that the active force in air, which produces so many effects, does really all arise from the fire contained in it.

F I R

Again: As all bodies placed in a very solid air, do, by degrees, grow cold, motionless, rigid, &c. i. e. though there be still some remains of fire, and in proportion as that is diminished, the effect is accelerated; it follows, that cold, a less degree of heat, is the effect of a lesser action of fire: and all action rises apparently from the same source.

Then, as fire can render the most solid bodies, as stone, metals, &c. (as appears very evident in large burning-glasses, in which gold itself immediately calcines, and emits fumes, i. e. becomes fluid) so the want of fire would convert the most fluid bodies, as spirits of wine, &c. into solids.

Fire is distinguished into two kinds, called elementary or pure fire, which is such as exists in itself, and alone is properly called fire; or common or culinary fire, which is raised and kindled from the former, and is that which agitates and affects ignited, combustible, and moveable bodies, the particles of which, joining with those of the pure fire, constitute pure flame.

This latter is improperly called fire, in that not only a small part of it is real or pure fire; and in ignited bodies, that which flames, smokes, &c. is not simply fire; whereas pure fire, such as is collected in a burning-glass, yields no flame, smoke, ashes, or the like.

Fire may be present in the greatest abundance, yet without any heat: this is evident in the tops of the highest mountains, illuminated by the sun, where the cold is always extremely pinching, and this even under the equator, there being mountains there which are perpetually covered with snow, though there can be no want of fire.

So a large burning-glass has no effect: the smallest warmth cannot be felt in its focus in a place where the sun does not shine, or when the sun is covered with a cloud, but a piece of metal may be seen to melt the very moment the sun emerges.

Fire may be in exceeding small quantity, and yet burn with great violence: thus spirit of wine when set on fire, does not burn the hands; and though poured on a piece of red-hot iron, does not take fire; so that the fire that is in, should not appear very great: yet if it meet with some harder body while it is burning, the particles of which body it is capable to agitate by the attrition of its own, it will yield a fierce flame, capable of burning a harder body than the hand.

From this it appears, that the relation of heterogeneous particles, agitated by the fire, has more effect in respect to heat than the action of the fire itself: nor need we be far to seek for the mechanical reason of this, for the particles of fire, being all equal and spherical, must of themselves be harmless; but if they carry certain spicula, or any other bodies along with them, then they become capable of doing much harm.

Hence, though the flame of a piece of wood may give a sense of heat, and burn such things as are applied to it, it does not therefore necessarily follow, that there is any pure fire in it, so that the distinction of pure and common fire is absolutely necessary: though this distinction has been overlooked by most or all the authors before Dr. Boerhaave, who have written on fire; which has led them into egregious mistakes, inasmuch that most of them have held, that the flame of a piece of wood is all fire, which appears to be false from what has been already said, and also what follows.

Elementary or pure fire is of itself imperceptible, and only discovers itself by certain effects that it produces in bodies, and these effects are only to be learnt by the changes which arise in bodies. These effects are three; 1st, heat; 2dly, dilatation in all solid bodies, and rarefaction in all fluids; 3dly, motion.

The first effect of elementary fire on bodies is heat: heat arises wholly from fire, and in such a manner, that the measure of heat is always the measure of fire; and that of fire, of heat; so the heat is inseparable from the fire.

F I R

The second effect of elementary fire is dilatation in all solid bodies, and rarefaction in all fluids.

Numerous experiments make it evident, that both these are inseparable from heat. If you heat an iron rod, it will increase in all its dimensions; and the more it is heated, the farther it will be increased; and being again exposed to the cold, it will contract, and successively return through all degrees of its dilatation, till it arrive at its first bulk, being never two minutes successively of the same magnitude.

The like may be observed in gold, the heaviest of all bodies, which takes up more space when it is fused than it did before; nay, even mercury, the heaviest of all fluids, has been known to ascend above thirty times its height, being placed over the fire in a tube.

The laws of this expansion are;

1st, That the same degree of fire rarefies fluids sooner, and in a greater degree than it does solids. Without this, the thermometer would be of no use; since, if it were otherwise, the cavity of the tube would be dilated in the same proportion as the fluid is rarefied.

2dly, By how much the liquor is lighter, by so much the more it is dilated by fire: thus air, which is the lightest of all fluids, expands the most, and spirit of wine the next after air.

The third effect of fire on bodies is motion; for fire, in warming and dilating bodies, must necessarily move their parts. And in effect, all the motion of nature arises from fire alone; and if this were taken away, all things would become immoveable. All oils, fats, waters, wines, ales, spirits of wine, vegetables, animals, &c. become hard, rigid, and inert, upon the absence of only a certain degree of fire; and this induration will be both the sooner, and the more violent, the less the degree of fire is.

Hence, if the fire was absolutely taken away, and there were the greatest degree of cold, all nature would grow into one concrete body, solid as gold, and hard as a diamond; but, upon the application of fire, it would recover its former mobility.

And, of consequence, every diminution of fire is attended with a proportionable diminution of motion.

Pure fire is found in two different manners, either as it exists every where, and is diffused equally in all places; or as it exists in certain bodies, in which it makes no great alteration.

That fire should exist in the same quantity in all places, will seem a strange paradox; and yet that it does so, is demonstrable from innumerable experiments.

This elementary fire is present every where, in all bodies, all space, and at all times, and that in equal quantities; for let a person go where he will, to the top of the highest mountains, or descend into the lowest cavern, whether the sun shine or not; either in the most scorching summer, or the sharpest winter; fire may be collected by several methods, as attrition or otherwise. In a word, there is no physical point assignable without fire, no place in nature where the attrition of two sticks will not render it sensible.

The Cartesians, as Marriotte, Perrault, &c. hold, That there is a large stock of fire in a perfect vacuum, i. e. a space out of which all the air has been exhausted, as supposing an absolute vacuum impossible: now, the most perfect vacuum that we can arrive at, is that of Mr. Huygens's contrivance, which is as follows: heat a quantity of the purest mercury to the heat of boiling water, and pour it into a hot tube of about forty inches long; and when the tube is filled, apply a finger upon the orifice of it, and thus invert it into a basin full of mercury: the mercury will now be suspended in the tube to the whole height; but then, if you give it but a little shake, it will sink down to the height of about twenty-nine inches, and thus leave a vacuity of eleven inches.

Yet here the philosophers above-mentioned deny there is any vacuum, and urge, that now so much the more fire is entered into the space as there was of other matter;

F I R

matter; but this is contrary to experience; at least, the fire contained there is no hotter than the mercury itself; for if a drop or two of water be in a frosty season sprinkled both upon the upper part of the tube, supposed to be full of fire, and on the lower that is full of mercury, they will in each place freeze alike; so that there is no more pure fire in a perfect vacuum, than in any other place.

But whereas it has been said, that fire is found in all bodies, to prove this, set gold against the vacuum before-mentioned, and this gold, though the most ponderous of all bodies, will not contain more fire than Huygens's vacuum, as appears from the thermometer.

But the fire in gold, when ready to fuse, is pure fire; for a mass of this being once heated red hot, will retain this fire perfectly for three days; nay, the prince of Mirandola and others, have kept gold ignited for two months, without any diminution of weight.

Mr. Gravesande, *Phys. Element*, says, That bodies of any kind, being violently moved against one another, will grow hot by such friction; and this to a considerable degree, which shews that all bodies have fire in them; for fire may be put in motion, and separated from a body by such rubbing, but can never be generated that way.

Mr. Boyle, *Mech. Prod. of Heat*, says, That although quicksilver is allowed to be the coldest of all fluids, inasmuch that many deny, that it will produce any heat by its immediate action on any other body, and particularly on gold; yet several trials have assured him, that a particular mercury may by preparation be enabled suddenly to insinuate itself into the body of gold, whether calcined or crude, and become manifestly hot with it in less than two or three minutes.

Mr. Gravesande says, That quicksilver contains fire, is evident hence, that if you shake it about in an exhausted glass, it will appear all luminous.

Elementary fire of itself always lies concealed; nay, it may be perfectly undiscoverable, where it is in the greatest quantity; as is evident in the torrid zone, where the snow never melts, notwithstanding the great abundance of fire.

This fire, in itself thus perfectly latent, may discover itself to be present by five effects; 1st, by rarefying bodies, and particularly air; 2dly, by light; 3dly, by colour; 4thly, by heat; and 5thly, by burning.

That there is a good quantity of fire even in the coldest places, and in the coldest bodies, is confirmed by the following experiment: if you take two large iron plates, and rub them briskly together in Iceland, which is only twelve degrees short of the north pole, in the most frosty season, and at midnight, they will grow warm, glow, shine, and heat to such a pitch as not only to rarefy the spirit in the thermometer, but even to ignite, and at last to fuse.

Now the fire here found is either created *de novo*, or it was there before, but nobody will assert its creation; and accordingly, unless it be furnished with a proper fuel, it will be soon dissipated again, but not annihilated; and of consequence it pre-existed, and it appears to be true fire by its rarefying the spirit in the thermometer.

From this, and many other experiments, it is evident, that fire is always found in all parts of space, and in all bodies equally spread on the utmost top of the highest mountain, as in the subject valley, or in the deepest cavern under ground, and in every climate, and at every season.

The equable distribution of fire in all places being proved, it should thence follow, that there is the same degree thereof every where; which would really be so, were it not that fire happens by one means or other to be more collected in one place than another.

But, notwithstanding the equable difference, &c. of fire through all the mundane space does not hinder, but that, to our senses, it appears very unequal in different places; and hence we have two vulgarly re-

F I R

puted sources or funds of fire, viz. in the sun, and the center of the earth.

As for the first, we have the concurrent opinions of the philosophers of all ages, but one excepted, who held the sun to be cold.

As to the second, the central fire, it is manifest that there is an ample proportion of fire under ground; and even, that fire appears much more abundant there than on the surface; so that at least, a subterraneous fire must be granted.

Thus they who dig mines, wells, &c. constantly observe, that while they are but a little below the surface, they find it a little cool; and as they proceed lower, it proves much colder, as being beyond the reach of the sun's heat, inasmuch that water will freeze almost instantaneously, and hence is the use of houses.

But a little lower, about forty or fifty feet deep, it begins to grow warmer, so that no ice can bear it; and then the deeper they go, still the greater heat; till at length it endangers the stoppage of respiration, and puts out their candles. If they venture yet farther with a lighted candle, the place shall be immediately found full of flame, as once happened in the coal-pits in Scotland, where a hardy digger, descending to an unusual depth, with a light in his hand, the fumes, which were there found very copious, caught fire thereby, and burnt the whole mountain down.

Therefore it seems as if nature had lodged another sun in the center of the earth, to contribute on its part to the giving motion to bodies, and for the promoting of generation, nutrition, vegetation, germination, &c. of animals, vegetables, and fossils.

As to the origin of this subterraneous sun, some doubt whether it were formed there in the beginning, like the sun in the firmament, or gradually produced by a secondary collection of vague fire into this place.

What makes in favour of the former opinion, are volcanos or burning mountains, which seem to have existed from the first ages; for the flames of mount *Ætna* are mentioned as of great antiquity, and there are likewise such mountains found in the coldest regions, viz. *Nova Zembla* and *Iceland*, as well as the hottest, as *Borneo*, &c.

It cannot be reasonably pretended, says Mr. Boyle, that the subterraneous heat proceeds from the rays of the sun, since they heat not the earth above six or seven feet deep, even in the southern countries; and if the lower part of the earth were of its own nature cold, and received the heat it affords only from the sun and stars, the deeper men descend therein, the less degree of heat and steams they would meet with.

The sun contributes much in bringing fire to light, by reason of his rapid motion round his axis; whereby the fiery particles, every where diffused, are directed and determined in parallel lines toward certain places where its effects become apparent.

And from thence it is, that the fire is perceived by us when the sun is above; but that when he disappears, his impulse or pressure being then taken away, the fire continues dispersed at large through the ethereal space.

There is not, in effect, less fire in our hemisphere in the night time, than there is in the day time; only it wants the proper determination to cause it to be perceived.

The effects of elemental fire may be increased divers ways, viz. first, by attrition; or a swift rubbing or agitating one body against another. This is very manifest in solids. The attrition of a flint against a steel produces sparks of fire; and likewise in fluids, the violent agitation of cream, by churning, will produce a sensible warmth, and separate it into butter; and this effect is rendered still more discernible by a thermometer.

And the heat of animal bodies is owing to the agitation and attrition of the parts of these juices against each other, and the sides of the vessels.

The second manner of increasing the effect of elementary fire is, by throwing a quantity of moist or green

green vegetables, cut down while full of sap, into a large heap, and pressing them close down; by which they grow warm, hot, smoke, and break out into flame.

A third way is by mixing certain cold bodies: thus water, and spirit of wine, being first warmed, grow much hotter by being mixed; also oil of cloves, cinnamon, &c. being mixed with spirit of wine, become exceeding hot, and burst forth like volcanos.

The like effects may be had from several hard and dry bodies, as sulphur and steel filings.

To conclude: on fire and the effects thereof, depend all fluidity of humours, juices, &c. all vegetation, putrefaction, fermentation, animal heat, &c.

As all the four elements, water, air, earth, and fire, are very conducive to the work of vegetation, and no one of them more than this of fire; I conclude, that these few hints, which I have collected from the most approved authors, concerning the nature and properties of it, as they may be useful, would not be unacceptable to the ingenious and studious practisers of horticulture, which induced me to insert them here.

FIR-TREE. See **ARIES.**

FISTULAR FLOWERS [Flores Fistulares, of Fistula, *Lat.* a pipe] such as are compounded of many long, hollow, small flowers, like pipes.

FLAMMULA JOVIS. See **CLEMATIS.**

FLOWER: a flower is a natural production which precedes the fruit, which includes the grain or seed.

Though a flower is a thing so well known, yet the definition of this part of a plant is as various almost as the authors who define it. Jungius defines it to be the more tender part of a plant, remarkable for its colour, or form, or both, cohering with the fruit. Yet this author himself confesses, that this definition is too narrow; for some of those bodies which he allows to be flowers are remote from the fruit.

Mr. Ray says, it coheres, for the most part, with the rudiments of the fruit. Thus the words, for the most part are hardly to be admitted into definitions.

Tournefort defines it to be a part of a plant very often remarkable for its peculiar colours, for the most part adhering to the young fruit, to which it seems to afford the first nourishment, in order to explicate its most tender parts. Which definition is still more deficient than the former, by this uncertain mode of expression.

Pontedera, the professor of botany at Padua, defines it to be a part of a plant unlike the rest in form and nature; if the flower has a tube, it always adheres to the embryo, or is very near it, for whose use it is subservient; but if it wants a tube, there is no embryo adhering.

This definition is far from being clear, for it is scarce intelligible, and is liable to this objection, that it may include some parts of a plant which no person ever called by that name; for a root, a stalk, or a leaf, are parts of a plant unlike the rest in form and nature, having no tube, and so do not adhere to any embryo, and thus by Pontedera's definition are flowers.

Monf. Jussieu, the Paris professor, seems not to have succeeded much better in this affair: he says, That is properly called a flower, which is composed of chives, and a pistillum, and is of use in generation. But this is too defective; for there are many plants in which the pistillum or style is found a considerable distance from the chives; there are many flowers

that have no pistillum, whether that word be taken to signify the embryo of the fruit, or its appendix, and many which have no chives.

But the late Monsieur Vaillant seems to be happier, in forming a clearer idea of this part of a plant. We find in the lecture he read in the Royal Garden at Paris, that the flowers, strictly speaking, ought to be reckoned the organs which constitute the different sexes in plants; seeing they are sometimes found without any covering, and that the coats or petals, which immediately encompass them, are designed only to cover and defend them: but (says he) as these coats are the most conspicuous and most beautiful part of the composition, which is called by the name of flower; to these coats therefore I give the name of flower, of whatsoever structure or colour they be; whether they encompass the organs of both sexes together, or contain only one of them, or only some parts depending on one of them, provided always that they be not of the same figure of the leaves of the plant.

But, in my opinion, Dr. Martyn has been happier, in his definition of a flower, than all those above-mentioned: he defines a flower to be the organs of generation of both sexes adhering to a common placenta, together with their common coverings; or of either sex separately, with its proper coverings, if it have any.

The parts of a flower are, 1. The germen or ovary; which is the rudiment of the fruit, and so is properly the female organ of generation.

2. The style, which is a body accompanying the ovary, either arising from the top of it, or standing as an axis in the middle, with the embryos of the seeds round it.

3. The summits, or apices, which are those bodies that contain the prolific powder, analogous to the male sperm in animals; and generally hang upon slender threads, which are called the chives or stamina.

The petals are those tender fine coloured leaves, which are generally the most conspicuous parts of a flower.

The empalement, or calyx, is those tender leaves which cover the other parts of a flower.

Flowers, according to the number of their petals, are called monopetalous, dipetalous, tripetalous, tetrapetalous, &c.

The structure of flowers is indeed very various; but, according to Dr. Grew, the generality have these three parts in common, viz. the empalement, the foliation, and the attire.

Mr. Ray reckons, that every perfect flower has the petals, stamina, apices, and stylus or pistil; and such as want any of these parts, he accounts imperfect flowers.

In most plants there is a perianthum, calyx, or flower-cup; which is of a stronger consistence than the flower itself, and designed to strengthen or preserve it.

Flowers are distinguished into male, female, or hermaphrodite.

The male flowers are those in which are the stamina, but have no germen or style, the same which botanists call staminateous flowers; these have no fruit.

The female flowers are such as contain the germen and style, or pistil, which is succeeded with fruit, and are called fruitful, or knitting flowers.

The hermaphrodite flowers are such in which the two sexes are contained, i. e. the male and female parts are found in the same flower, which are the most general kind; such are the Daffodil, Lily, Tulip, Althæa, Geranium, Rosemary, Sage, Thyme.

The structure of parts is much the same in those where the sexes are divided; the difference between them consisting in this, that the stamina and summits or apices, i. e. the male parts in these are separate from the styles or pistils; being sometimes on the same plants, and sometimes on different ones.

Among the plants which bear both male and female parts, but at a distance from each other are reckoned the

the Cucumber, Melon, Gourd, Turkey-Wheat, Walnut, Oak, Beech, &c.

FLUIDITY. [*Fluiditas*, of *fluere*, *Lat.* to flow.]

Having occasion to mention fluids and fluidity, in speaking of the properties of the elements air, water, fire, &c. I thought it necessary, in this place, to give the following account of that property, which I have extracted from the most approved authors.

A fluid, or fluid body, is by some defined to be a body, whose particles are but weakly connected, their mutual cohesion being, in a great measure, prevented from some external cause: in which sense, a fluid stands opposed to a solid; and is, by the excellent Sir Isaac Newton, defined to be onewhole parts easily give place, or move out of the way, on any force impelled upon them, and by that means do so easily move one over another. Which definition is much better than that of Descartes, That a fluid is a body whose parts are in continual motion, because it is neither apparent that the parts of all fluids are so, nor that the parts of some solid bodies are not so.

Fluidity is the state or affection of bodies, which denominates or renders them fluid, and stands in direct opposition to firmness and solidity.

It is distinguished from liquidity and humidity, in that the idea of fluidity is absolute, and the property contained within the thing itself; whereas that of humidity is relative, and implies wetting, or adhering, i. e. something that gives us the sensation of wetness or moisture, and would have no existence, but for our senses.

Thus melted metals, air, æther, and even smoke, and flame itself, are fluid bodies, and not liquid ones; the parts of them being actually dry, and not leaving any sense of moisture.

Fluidity seems to consist in this, that the parts of any body, being fine and small, are so disposed by motion and figure, as that they can easily slide over one another's surfaces all manner of ways. Mr. Boyle also observes, That it is requisite they should be variously and separately agitated to and fro, and that they should touch one another but in some parts only of their surfaces. And the same gentleman says, in his History of Fluidity, That the conditions requisite to constitute a fluid body, are chiefly the three following.

1st, The minuteness or smallness of its parts: thus we see the fire, by dividing metals into parts very fine and small, will melt them, and make them fluid; and after the same manner do acid menstrua dissolve them, suspend their liquor, and render them fluid; and that fire turns the hard body of common salt almost wholly into a liquor by distillation: though it is not improbable, but that the shape and figure of these small parts may conduce much towards producing this quality of fluidity; for it is found in the distillation of Olive oil (which is a fluid made only by pressure) that most of the oil will, by the action of the parts of the fire (if it be done in a retort) be turned into a kind of consistent substance like butter.

Likewise mercury, whose parts are, without doubt, much grosser than those of oil and water, is yet more fluid than either of them.

2dly, It seems requisite to fluidity, that there be store of vacuities, or vacant spaces, interspersed between the corpuscles of the fluid body; for else there will not be room for each particle to continue its motion and agitation on the surfaces of the neighbouring ones. For,

3dly, The chief condition requisite to constitute a fluid body is, that its particles be agitated variously and apart, either by their own proper motion, or by something of substance, that tumbles them up and down by its passage through them.

That this qualification is chiefly requisite to fluidity, you may gather from that common experiment of putting a little dry powder of alabaster, or plaster of Paris, finely sifted, in a flat-bottomed vessel over the fire; for in a little time it will boil like water, and imitate all the motions of a boiling liquor; it will

tumble variously over in great waves like that; it will bear stirring with a stick or ladle without resisting, as it will do when cold; nay, if it be stirred strongly near the side of the vessel, its waves will apparently dash up against the sides: yet if any of it be speedily taken out, and laid on a piece of paper, you will see nothing but a dry powder.

So that it is evident from hence, that there is a real difference between a fluid body and a wetting liquor: for not only this boiling powder and melted metals, but the air and æther, and even flame itself, are properly fluid bodies, though not moist liquors.

This ingenious gentleman found also, that by blowing the smoke of Rosemary into a glass pipe, and then holding the pipe (when filled) upright, the surface of the smoke would accommodate itself to a level situation; and which way soever the tube was inclined, the superficies of the smoke would be parallel to the horizon; and when the glass was much inclined, would run along it like water.

From whence he infers, that, in order to the rendering a body fluid, there is no need that its parts should be closely condensed, as those of water are.

And Dr. Hook, in his Micrograph. p. 12. presents us with a very pretty experiment or two, to prove this account of fluidity, viz. That a dish of sand being set on a drum head, briskly beaten by the sticks, or on the upper stone of a mill, turning swiftly round on the (empty) lower one, it in all respects, emulate the properties of a fluid body; for a heavy body will immediately sink in it to the bottom, and a light one emerge to the top; each grain of sand hath a constant vibrating, dancing motion; and if a hole be made in the side of the dish, the sand will spin out like water.

The corpuscular philosophy, before it was wonderfully improved by Sir Isaac Newton, did not go to the bottom of this matter; for it gave no account of the cause of the chief condition requisite to constitute a fluid body, viz. the various motions and agitations of its particles: but this may, in a great measure, be accounted for, if it be supposed to be one of the primary laws of nature, That as all particles of matter attract one another when they come within a certain distance, so likewise they fly away from, and avoid one another, at all greater distances from one another.

For then, though their common gravity may keep them together in a mass (it may sometimes be) together with the pressure of other bodies upon them; yet their continual endeavour to avoid one another singly, and the adventitious impulses of light, heat, or other external causes, may make the particles of fluids continually move round about one another, and so produce this quality.

It is indeed a difficulty not easily got over, to account for the particles of fluids always keeping at such a distance from one another, as not to come within the sphere of one another's attraction.

The fabric and constitution of that fluid body, water, is amazing; that a body so very rare, and which has a vast over-proportion of pores, or interspersed vacuity, to solid matter, should yet be perfectly incompressible by the greatest force; and yet this fluid is easily reducible into that firm, transparent, friable body which we call ice, by being only exposed to a certain degree of cold.

One would think, that though the particles of water cannot come near enough to attract each other, yet the intervening frigorific matter doth, by being mingled per minima, strongly attract them, and is itself likewise strongly attracted by them, and wedges or fixes all the mass into a firm body; which solid body loses its solidity again, when by heat the vinculum is solved, and these frigorific particles are disjoined from those of the water, and are forced to fly out of it; and, perhaps, just thus may the fumes of lead fix quicksilver.

When a firm solid body, such as a metal, is by heat reduced into a fluid, doth not the fire disjoin and se-

parate its constituent particles, which mutual attraction caused to cohere before, and keep them at such a distance from each other, as that they are without the sphere of one another's attraction as long as that violent motion lasts? And do not they, when that is over, and the heat is flown out, come nearer to, attract one another, and coalesce again?

As therefore the cause of cohesion of the parts of solid bodies appears to be their mutual attraction, so the chief cause of fluidity seems to be a contrary motion impressed on the particles of fluids, by which they avoid and fly one another, as soon as they come at, and as long as they keep at, such a distance from each other.

It is observed also in fluids, that the direction of their pressure against the vessels which contain them, is in lines perpendicular to the sides of such vessels; which property being the necessary result of the particles of any fluid's being spherical, it shews that the parts of all fluids are so, or of a figure nearly approaching thereto.

Dr. Clarke says, That if the parts of a body do not touch each other, or easily slide over one another, and are of such a magnitude as that they may be easily agitated by heat, and the heat be sufficiently great to agitate them; though perhaps it may be less than suffices to prevent water from freezing; or even though the parts be not actually moved, yet if they be small, smooth, slippery, and of such a figure and magnitude as disposes them to move and give way, that body is fluid.

And yet the particles of such fluid bodies do, in some measure, cohere; as is evident hence, that mercury, when well purged of air, will be sustained in the barometer to the height of sixty or seventy inches; that water will ascend in capillary tubes, even in vacuo; and that the drops of liquors in vacuo run into a spherical form, as adhering by some mutual cohesion, like that between polished marble planes.

To this may be added, that these said bodies, if they consist of particles which are easily entangled with each other, as oil; or if they be capable of being stiffened by cold, and joined by the interposition of certain cunei or wedges, as water, they are easily rendered hard; but if their particles are such as can neither be entangled as air, nor stiffened by cold, as quicksilver, then they never grow hard and fixed.

In short, the Cartesians define a fluid to be a body, the parts of which are in continual intestine motion; and Dr. Hook, Mr. Boyle, and Dr. Boerhaave, tho' they differ in opinion widely from Cartesianism, subscribe to the definition, and alledge arguments to prove, that the parts of fluids are in continual motion; and even that it is this motion which constitutes fluidity; and the latter of them ascribes this, and all motion, to fire. See FIRE.

Fluids then are either natural, as water and mercury; or animal, as blood, milk, bile, lymph, urine, &c. or factitious, as wines, spirits, oils, &c.

FŒNICULUM. Tourn. Inst. R. H. 311. tab. 164. Anethum. Lin. Gen. Plant. 326. *Fennel*; in French, *Fenouil*.

The CHARACTERS are,

It hath an umbellated flower; the great umbel is composed of many smaller, which have no involucre; the umbel is uniform; the flowers have five incurved petals, and five stamina, terminated by roundish summits: the germen is situated under the flower, supporting two small styles, crowned by roundish stigmas. The germen afterward turns to an oblong fruit, deeply channelled, dividing into two parts, each containing a single seed, flat on one side, but convex and channelled on the other.

This genus of plants is ranged in the second section of Tournefort's seventh class, which includes the herbs with umbellated flowers disposed circularly, whose empalement turns to two narrow, oblong, thick seeds. Dr. Linnæus has joined this genus to Anethum, which is placed in the second section of his fifth class, with those plants whose flowers have five stamina and two styles. But as the seeds of Fennel are oblong,

thick, and channelled, and those of Dill flat and bordered, it is much better to keep them separate, than to join them in the same genus.

The SPECIES are,

1. **FŒNICULUM** (*Vulgare*) foliis decompositis, foliolis brevioribus multifidis, semine brevior. *Fennel with decomposed leaves, whose small leaves are shorter and end in many points, and a shorter seed.* Fœniculum vulgare Germanicum. C. B. P. 147. *Common Fennel.*
2. **FŒNICULUM** (*Dulce*) foliis decompositis, foliolis longioribus, semine longiori. *Fennel with decomposed leaves, whose small leaves are very long, and a longer seed.* Fœniculum dulce, majore & albo semine. J. B. 3. p. 2, 4. *Sweet Fennel having a larger white seed.*
3. **FŒNICULUM** (*Azoricum*) humilius, radice caulescente carnosio, seminibus recurvis, radice annuâ. *Dwarf Fennel with a fleshy stalk, recurved seeds, and an annual root.* Fœniculum dulce Azoricum. Pluk. Alm. *Sweet Azorian Fennel, called Finocchio.*

The first sort is the common Fennel, which is cultivated in the gardens, and has sown itself in many places, where it has been introduced in such plenty, as to appear as if it were a native in England; but it is no where found at a great distance from gardens, so has been undoubtedly brought into England. There are two varieties of this, one with light green leaves, and the other with very dark leaves; but these I believe are only varieties which arise from the same seeds; but this is very difficult to ascertain; for unless the seeds were sown separately in some place where neither of these plants have been growing before, it cannot be done; for the seeds of these plants which have scattered, will remain in the ground some years, and when exposed near the surface will grow; so that the plants become troublesome weeds, wherever their seeds have been suffered to scatter; and they frequently come up where other seeds are sown, and thereby the two sorts may accidentally mix.

The common Fennel is so well known, as to need no description. This hath a strong fleshy root, which penetrates deep into the ground, and will continue several years. It flowers in July, and the seeds ripen in autumn. The best time to sow the seeds, is soon after they are ripe; the plants will come up in the autumn or the following spring, and require no other care but to keep them clean from weeds, and thin the plants where they are too close; it will grow in any soil or situation. The leaves, seeds, and roots of this, are used in medicine; the root is one of the five opening roots, and the seed one of the greater carminative seeds. There is a simple water made from the leaves, and a distilled oil from the seed.

The sweet Fennel has been by many supposed only a variety of the common sort, but I have cultivated it in the same ground with that, where it has always retained its differences. The leaves of this are very long and slender, growing more sparsely, and do not end in so many points as those of the common sort; the stalks do not rise so high, and the seeds are longer, narrower, and of a lighter colour. These seeds are generally imported from Germany or Italy, and are by some preferred to those of the common sort for use, being much sweeter.

This may be propagated in the same manner as the former sort, being very hardy, but the roots are not of so long duration.

The third sort is supposed to have been originally brought from the Azorian Islands; it has been long cultivated in Italy as a salad herb, under the title of Finocchio; and there are some few gardens in England, where it is now cultivated, but in small quantities, for there are not many English palates which relish it, nor is it easy to be furnished with good seeds; those which are annually brought from Italy seldom prove good; and it is difficult to save it in England, because the winter frequently kills those plants which are left for seeds; and when any good plants of the early sowing are left for seeds, they do not ripen, unless the winter proves very favourable.

This

This sort hath very short stalks, which swell just above the surface of the ground, to four or five inches in breadth, and almost two thick, being fleshy and tender: this is the part which is eaten when blanched, with oil, vinegar, and pepper, as a cold salad. When these plants are permitted to run for seeds, the stalks do not rise more than a foot and a half high, having a large spreading umbel standing on the top. The seeds of this sort are narrow, crooked, and of a bright yellow colour; they have a very strong smell like Aniseed, and are very sweet to the taste.

The manner of cultivating this plant is as follows: Your first care must be to procure good seeds from some person who has been careful in the choice of the plants, otherwise there will be little hope of having it good; for the plants will run up to seeds before they swell to any size, so will not be fit for use: then make choice of a good spot of light rich earth, not dry nor very wet, for in either extreme this plant will not thrive. The first crop may be sown about a fortnight in March, which, if it succeeds, will be fit for use in July; and by sowing at several times, there may be a supply for the table till the frost puts a stop to it. After having well dug and levelled the ground smooth, you must make a shallow drill by a line, into which you must scatter your seeds pretty thin; for if your plants are six inches asunder in the rows, it will be full near enough; but however, you must expect some of your seeds to fail, and therefore you should scatter them about two inches distance; then cover the seeds about half an inch thick with earth, laying it smooth: these drills should be made eighteen inches asunder, or more, that there may be room to clean the ground, as also to earth up the plants when they are full grown. When the plants come up, which will be in about three weeks or a month after sowing, you must with a small hoe cut up all the weeds between them, and where the plants are too close, they should be thinned to about three inches distance; and as they advance, and the weeds spring again, they should, from time to time, be hoed; and at the last time of thinning them, they should be left seven or eight inches asunder at least. If your kind be good, the stems of the plants will increase to a considerable bulk just above the surface of the ground; which part should be earthed up in the manner of Celery, to blanch, about a fortnight or three weeks before it is used, and this will cause it to be very tender and crisp.

Your second crop should be sown about three weeks after the first, and so continue sowing every three weeks or a month till the end of July, after which time it will be too late for the plants to come to any perfection. But you should observe to sow in April, May, and June, on a moister soil than that which you sowed the first on; as also what you sow in the latter part of July, should be sown on a drier soil, and in a warmer situation; because this crop will not be fit for use till late in autumn, and therefore will be subject to injuries from too much wet or cold weather, if on a moist soil. But as the ground is often extreme dry in June and July, and the seeds more apt to miscarry and not come up, you should therefore observe to water and shade the beds where this seed is sown at that season, until the plants come up. And if the season should prove dry, the plants must be duly watered, otherwise they will run up to seed before they are of any size; therefore there should be a channel made where every row of plants grow, to detain the water which is poured on them, to prevent its running off. In the autumn, if there should happen sharp frosts, it will be very proper to cover the plants with some Peas-haulm, or other light covering, to prevent their being pinched; by which method they may be continued for use till the middle of winter.

A small bed of this plant will be sufficient at each sowing for a middling family; and for a large family, a bed of about twenty feet long, and four feet broad, will be full enough at a time.

FÆNUM BURGUNDIACUM. See *MADICA SATIVA*.

FÆNUM GRÆCUM. See *TRIGONELLA*.

FOOT-STALKS, are those small stalks which immediately sustain the leaves, flowers, or fruit.

FOUNTAINS are sources or springs of living water, arising out of the ground. As to the original of them, see under the article *SPRINGS*.

Of artificial fountains there are great variety, the mechanism of which not being to my purpose, I will not dwell upon it; though I may assert, that they are not only great ornaments to a fine garden, but also of great use. But they ought not to be placed too near the house by reason of the vapours that arise from the water, which may be apt to strike a damp to the wall, and spoil the paintings, &c. and the summer vapours may cause a malignity in the air, and so be prejudicial to the health of the family; and likewise the noise may be incommodious in the night.

Fountains in a garden should be so distributed, that they may be seen almost all at one time, and that the water-spouts may range all in a line one with another, which is the beauty of them; for this occasions an agreeable confusion to the eye, making them appear to be more in number than they really are. See *JET D'EAU, SPRINGS, VAPOURS, WATER, &c.*

FRAGARIA. Lin. Gen. Plant. 558. Tourn. Inst. R. H. 295. tab. 152. [is so called for its fragrant aromatic scent.] Strawberries; in French, *Fraiser*.

The **CHARACTERS** are,

The empalement of the flower is of one leaf, which is cut into ten parts at the top. The flower hath five roundish petals, which are inserted in the empalement, and spread open. It hath twenty stamina, which are inserted in the empalement, terminated by moon-shaped summits. It hath a great number of germen collected into a head, each having a single style, inserted in the side of the germen, crowned by single stigmas; this head afterward becomes a large, soft, pulpy fruit, which, if left, falls away, leaving many small angular seeds in the empalement.

This genus of plants is ranged in the fifth section of Linnæus's twelfth class, which includes those plants whose flowers have at least twenty stamina and many styles, which are inserted to the empalement.

The **SPECIES** are,

1. **FRAGARIA** (*Vesca*) foliis ovatis serratis, calycibus brevibus, fructu parvo. *Strawberry with oval sawed leaves, short empalements, and a small fruit. Fragaria vulgaris. C. B. P. 226. The common or Wood Strawberry.*
2. **FRAGARIA** (*Virginiana*) foliis oblongo-ovatis serratis, infernè incanis, calycibus longioribus, fructu subrotundo. *Strawberry with oblong, oval, sawed leaves, hoary on their under side, longer empalements, and a roundish fruit. Fragaria Virginiana fructu Coccineo. Hist. Ox. 2. 186. Virginia Strawberry with a scarlet fruit, commonly called the Scarlet Strawberry.*
3. **FRAGARIA** (*Muricata*) foliis ovato-lanceolatis rugosis, fructu ovato. *Strawberry with oval, spear-shaped, rough leaves, and an oval fruit. Fragaria fructu parvi pruni magnitudine. C. B. P. 327. Strawberry with fruit as large as a small Plum, commonly called Hautboy Strawberry.*
4. **FRAGARIA** (*Chiloensis*) foliis ovatis carnosissimis hirsutis fructu maximo. *Strawberry with oval, fleshy, hairy leaves, and a large fruit. Fragaria Chiloensis, fructu maximo foliis carnosissimis hirsutis. Hort. Elth. 145. tab. 120. Strawberry of Chili with a large fruit, and hairy fleshy leaves, called Frutilla, in America.*

There are some other varieties of this fruit, which are now cultivated in England; but I have not seen any other which can be called a distinct species, than are here enumerated, and these, I think, may be allowed to be so, for they never alter from one to the other, by any cultivation, though the fruit is frequently improved, so as to be of a larger size thereby; therefore those who have supposed them but one species, have greatly erred in so doing; I shall therefore mention the several varieties of Strawberry, which are

at present to be found in the gardens under the species to which they naturally belong.

The first sort is the common Wood Strawberry, which grows naturally in the woods in many parts of England, and is so well known as to need no description; of this there are three varieties, 1. The common sort with red fruit. 2. The white Wood Strawberry, which ripens a little later in the season, and is by many persons preferred to it for its quick flavour, but as it seldom produces so large crops of fruit as the red sort, it is not very generally cultivated. 3. The green Strawberry, by some called the Pine Apple Strawberry, from its rich flavour. The fruit of this is greenish when ripe; it is very firm, and hath a very high flavour; this is a late ripe fruit, but unless it is planted in a moist loamy soil, it is a very bad bearer; but in such land where it does succeed, it merits cultivation as much as any of the sorts.

The Scarlet Strawberry is the sort which is first ripe, for which reason it merits esteem, had it nothing else to recommend it; but the fruit is so good, as by many persons of good taste to be preferred to most other sorts. This was brought from Virginia, where it grows naturally in the woods, and is so different from the Wood Strawberry in leaf, flower, and fruit, that there need be no doubt of their being distinct species.

There is a variety of this which hath been of late years introduced from the northern parts of America, which has the appearance of a distinct species. The leaves of this are rounder, and not so deeply veined; the crenatures on their edges are broader and more obtuse. The leaves which compose the empalement are much longer, and are hairy, and the fruit is larger; but as in other respects it approaches near to the Scarlet Strawberry, I have chosen to join it to that, rather than make a distinct species of it; this I have been informed grows naturally in Louisiana.

There has also been another variety of this (if not a distinct species) lately introduced to our gardens, which is commonly known by the title of Alpine Strawberry; the plants of this greatly resemble those of the Scarlet Strawberry, but the fruit is more pointed; it is a well flavoured fruit, and continues bearing from the common season of Strawberries, until the frost in autumn puts a stop to it, which renders the sort very valuable: I have frequently gathered the fruit in the beginning of November; this has occasioned the Dutch gardeners titling it Everlasting Strawberry.

The Hautboy Strawberry, which the French call Capitons, came originally from America, but it has been long cultivated in the English gardens, and is very different from the other sorts in leaf, flower, and fruit, as that no one can doubt of their being different species; there is an improvement of this sort, which is commonly called the Globe Hautboy. The fruit of this is larger, and of a globular form, but this difference has certainly arisen from culture; for where these have been neglected a year or two, they have degenerated to the common Hautboy again; where the ground is proper for this plant, and their culture is well managed, the plants will produce great plenty of fruit, which will be large, and well flavoured, and by some persons are preferred to all the other sorts.

The Chili Strawberry was brought to Europe by Mons. Frazier, an engineer, who was sent to America by the late king of France, and was first planted in the Royal Garden at Paris, from whence it was communicated to several curious persons in Holland, and in the year 1727, I brought a parcel of the plants to England, which were communicated to me by Mr. George Clifford, of Amsterdam, who had large beds of this sort growing in his curious gardens at Hartecamp. The leaves of this sort are hairy, oval, and of a much thicker substance than any sort yet known, and stand upon very strong hairy foot-stalks; the runners from the plants are very large, hairy, and

extend to a great length, putting out plants at several distances. The foot-stalks which sustain the flowers are very strong; the leaves of the empalement are long and hairy. The flowers are large, and are often deformed; and so is the fruit, which is very large, and when cultivated in very strong land, the plants produce plenty of fruit, which is firm, and very well flavoured; but as it is a bad bearer in most places where it has been cultivated, it has generally been neglected.

The Strawberries in general love a gentle hazelly loam, in which they will thrive and bear greater plenty of fruit than in a light rich soil. The ground should also be moist, for if it is very dry, all the watering which is given to the plants in warm dry seasons, will not be sufficient to procure plenty of fruit; nor should the ground be much dunged, for that will cause the plants to run into suckers, and grow luxuriant, and render them less fruitful.

The best time to remove these plants is in October, that they may get new roots before the hard frost sets in, which loosens the ground; so that if the roots of the plants are not pretty well established in the ground, the plants are frequently turned out of the ground by the first thaw; therefore the sooner they are planted when the autumnal rains begin, the better will their roots be established, so there will be less danger of their miscarrying, and sometimes those which are well rooted, will produce a few fruit the first year; there are some who transplant their plants in the spring; but where that is done, they must be duly supplied with water in the dry weather, otherwise they will not succeed.

The ground in which these are planted should be thoroughly cleaned from the roots of Couch, and all other bad weeds; for as the Strawberry plants are to remain three years before they are taken up, so if any of the roots of those bad weeds are left in the ground, they will have time to multiply so greatly as to fill the ground, and overbear the Strawberry plants. The ground should also be well trenched and made level; then the usual method is to lay it out into beds of four feet broad, with paths two feet or two feet and a half broad between each; these paths are necessary for the convenience of gathering the fruit, and for weeding and dressing of the beds, and also for watering the plants; after the beds are marked out, there should be four lines drawn in each, at a foot distance, which will leave six inches space on each side, between the outside rows and the paths; then the plants should be planted at about a foot distance from each other in the rows, in a quincunx order, being careful to close the ground to the roots of the plants when they are planted; and if there should not happen rain soon after, the plants should be well watered to settle the earth to their roots.

The distance here mentioned for the plants to be placed must be understood for the Wood Strawberries only, for as the other sorts grow much larger, their distances must be proportioned to their several growths; therefore the Scarlets and Hautboys should have but three rows of plants in each bed, which should be at fifteen inches distance, and the plants in the rows should be allowed the same space from each other, and the Chili Strawberry must have but two rows of plants in each bed, which should also be two feet apart in the rows; for as these grow very strong, if they have not room to spread, they will not be very fruitful.

In chusing proper plants of any of the sorts, depends the whole success; for if they are promiscuously taken from beds without care, great part of the plants will become barren; these are generally called blind, which is when there are plenty of flowers, but no fruit produced; if these flowers are well examined, they will be found to want the female organs of generation, most of them abounding with stamina, but there are few, if any styles; so that it frequently happens among these barren plants, that some of them will have a part of an imperfect fruit formed, which will

will sometimes ripen; this barrenness is not peculiar to Strawberries, but is general to all those plants which have creeping roots, or stalks; and the more they increase from either, the sooner they become barren, and this in some degree runs through the vegetable kingdom; for trees and shrubs which are propagated by cuttings, are generally barren of seeds in two generations, that is, when they are propagated by cuttings, which were taken from plants raised by cuttings; this I have constantly found to hold in great numbers of plants, and in fruit-trees it often happens, that those sorts which have been long propagated by grafts and buds, have no kernels. But to return to the choice of the Strawberry plants; these should never be taken from old neglected beds, where the plants have been suffered to spread or run into a multitude of suckers, nor from any plants which are not very fruitful; and those offsets which stand nearest to the old plants, should always be preferred to those which are produced from the trailing stalks at a farther distance; and the Wood Strawberry is best when the plants are taken fresh from the woods, provided they are taken from fruitful plants, because they are not so liable to ramble and spread, as those which are taken from plants, which have been long cultivated in gardens; therefore those who are curious in cultivating this fruit, should be very careful in the choice of their plants.

When the plants have taken new root, the next care is if the winter prove severe, to lay some old tanners bark over the surface of the bed between the plants, to keep out the frost: this care is absolutely necessary to the Chili Strawberry, which is frequently killed in hard winters, where they are exposed without any covering; therefore where tanners bark cannot easily be procured, saw-dust, or sea-coal ashes may be used; or in want of these, if decayed leaves of trees, or the branches of Evergreen-trees with their leaves upon them, are laid over the beds, to prevent the frost from penetrating deep into the ground, it will secure the plants from injury.

The following summer the plants should be constantly kept clean from weeds, and all the runners should be pulled off as fast as they are produced; if this is constantly practised, the plants will become very strong by the following autumn; whereas when this is neglected (as is too frequently seen) and all the runners permitted to stand during the summer season, and then pulled off in the autumn, the plants will not be half so strong as those where that care has been taken; therefore there will not be near the same quantity of fruit upon them the following spring, nor will the fruit be near so large and fair; and where proper care is taken of the plants the first summer, there is generally a plentiful crop of fruit the second spring; whereas when this is neglected, the crop will be thin and the fruit small.

As this fruit is very common, there are but few persons who cultivate it with proper care; therefore I shall give some directions for the doing of it, which, if carefully practised, will be attended with success. The old plants of Strawberries are those which produce the fruit, for the suckers seldom produce any till they have grown a full year; therefore it appears how necessary it is to divest the old plants of them; for wherever they are suffered to remain, they rob the fruitful plants of their nourishment in proportion to their number; for each of these suckers send out a quantity of roots, which interfere, and are so closely-matted together, as to draw away the greatest part of the nourishment from the old roots, whereby they are greatly weakened; and these suckers also render each other very weak, so that from hence the cause of barrenness arises; for I have known where the old plants have been constantly kept clear from suckers, they have continued very fruitful four or five years without being transplanted; however, it is the best way to have a succession of beds, that after three years standing they may be taken up; because by that time they will have exhausted the ground of those vegetable

salts, necessary for the nourishment of that species of plants; for it is always observed, that Strawberries planted on fresh land are the most fruitful.

The next thing to be observed, is in autumn to divest the plants of any strings, or runners, which may have been produced, and also of all the decayed leaves, and the beds cleared from weeds; then the paths should be dug up, and the weeds buried which were taken from the beds, and some earth laid over the surface of the beds between the plants; this will strengthen the plants, and prepare them for the following spring; and if after this, there is some old tanners bark laid over the surface of the ground between the plants, it will be of great service to them. In the spring, after the danger of hard frost is over, the ground between the plants in the beds should be forked with a narrow three-pronged fork, to loosen it, and break the clods; and in this operation, the tan which was laid over the surface of the ground in autumn will be buried, which will be a good dressing to the Strawberries, especially in strong land; then about the end of March, or the beginning of April, if the surface of the beds is covered with moss, it will keep the ground moist, and prevent the drying winds from penetrating the ground, and thereby secure a good crop of fruit; and the moss will preserve the fruit clean, that when heavy rains may fall after the fruit is full grown, there will be no dirt washed over them, which frequently happens, so that the fruit must be washed before it is fit for the table, which greatly diminishes its flavour; therefore where this method is practised, the fruit may be had in perfection.

The soil in which the Chili Strawberry is found to succeed best, is a very strong brick earth, approaching near to clay; in this soil I have seen them produce a tolerable good crop, and the fruit has been extremely well flavoured; and if some care be taken to pull off the runners as they are produced, so as to leave only the old plants, I make no doubt but these plants may be as fruitful as the common Hautboy: this I mention from one or two experiments, which have been made by my direction, and not from theory.

There are some persons who are so fond of Strawberries, as to be at any expence to obtain them early in the year, and to continue them as late in the season as possible; and should I omit to give some directions for both these managements, they would suppose the book very defective; therefore I shall mention the practice of some few, who have succeeded best in the management of these fruits; I shall begin with directions for obtaining these fruits early in the spring. Where there are any hot walls erected in gardens for the producing early fruit, it is very common to see Strawberries planted in the borders; that the fire which is applied for ripening the fruit against the walls, may also serve the purpose of bringing forward the Strawberries; but where this is practised, the Strawberry plants should be annually renewed, taking up the plants as soon as their fruit is over, and all the earth of the borders should be taken out; at least two feet deep, and fresh earth brought in, which will be equally good for the wall trees; but, as was before observed, that the old plants of Strawberries only are those which produce the fruit, there should be a sufficient number of plants brought up in pots, to supply the border annually; and the same must be done if they are to be raised in a common hot-bed, or in stoves; therefore I shall begin with giving directions for raising and preparing plants for those purposes.

The sorts which are the most proper for forcing early, are the Scarlet, the Alpine; and the Wood Strawberries; for the Hautboy grows too large for this purpose. In the choice of the plants, there should be an especial care taken to have them from the most fruitful plants, and those which grow immediately to the old plants; they should be taken off in autumn, and each planted in a separate small pot filled with loamy soil, and placed in a shady situation till they have taken root; after which they may be removed to an open situation, where they may remain till the middle or

end of November, when the pots should be plunged into the ground up to their rims, to prevent the frost from penetrating through the side of the pots; if these are placed near a wall, pale, or hedge, exposed to an east aspect, or north-east, they will succeed better than in a warm situation, because they will not be forced too forward; the only care they require, is to secure them from being turned out of the pots after frost. The spring following the plants will be so far advanced as to have filled the pots with their roots by the end of April, when they should be turned out of the pots, and their roots pared; then planted into penny pots filled with the like loamy soil, and plunged into the ground in a shady situation, where they should remain the following summer; during which time they must be duly kept clean from weeds, and all the runners must be taken off as fast as they are produced; likewise if there should be any flowers come out, they should also be pinched off, and not suffered to bear fruit, which would weaken the plants, for there cannot be too much care taken to have the plants as strong as possible, that they may produce plenty of fruit, without which they are not worth the trouble of forcing.

About the middle of October, or earlier, if the autumn proves cold, the pots should be removed into a warmer situation, to prepare them for forcing; for they should not be suddenly removed from a very cold situation immediately into the stove or hot-bed, but be gradually prepared for it; but where they are designed for the borders near a hot wall, they may then be turned out of the pots, and planted into the borders, that they may have time to get fresh rooting, before the fires are made to heat the walls; when these are planted, they may be placed very close to each other; for as they are designed to remain there no longer than till they have ripened their fruit, they will not require much room, as their roots will find sufficient nourishment below, and also from the earth which is filled into the spaces between the balls of earth, about their roots; and it is of consequence to get as much fruit as possible in a small space, where there is an expence to force them early. If the fires are lighted about Christmas, the Strawberries in these borders will be ripe the end of March; or if the season should prove very cold, it may be the middle of April before they will be fit for the table.

In the management of the plants there must be care taken to supply them with water when they begin to shew their flowers, otherwise they will fall off without producing any fruit; and, in mild weather, there should be fresh air admitted to them every day; but as fruit-trees against the wall must be so treated, the same management will agree with the Strawberries.

If the Strawberries are intended to be forced in a stove, where there are Pine-apples, and no room to plunge them in the tan-bed, then the plants should be transplanted into larger pots in September, that they may be well rooted before they are removed into the stove, which should not be till December; but if they are placed under a frame the beginning of November, where they may be screened from the frost, it will prepare the plants better for forcing; and those who are desirous to have them very early, make a hot-bed under frames, upon which they place their plants the latter end of October, which will bring them forward to flower, and then they remove the plants into the stove; when these plants are removed into the stove, they should be placed as near to the glasses as possible, that they may enjoy the full sun and air; for when they are placed backward, the plants will draw up weak, and the flowers will drop without producing fruit. As the earth in the pots will dry pretty fast when they stand dry upon the pavement of the hot-house, or on shelves, so the plants must be duly watered; but it must be done with discretion, and not too much given to them, which will be equally hurtful to them; if these plants are properly managed, they will produce ripe fruit in February, which is as early as most people will chuse to eat them. When the fruit is all gathered from the plants, they

should be turned out of the stove; for as they will be of no farther service, they should not remain to take up the room; nor should those plants which are planted in the borders near the hot walls be left there after their fruit is gathered, but immediately taken up, that they may rob the fruit-trees of their nourishment as little as possible.

Where there is no conveniency of stoves, or hot-walls for this purpose, the fruit may be ripened upon common hot-beds; and though they may not be quite so early as with the other advantages, yet I have seen great crops of the fruit ripe in April, which were upon common hot-beds under frames, and executed at a small expence in the following manner.

The plants were prepared in pots after the manner before directed, which were placed in a warm situation in the beginning of October, and about Christmas the hot-bed was made in the same manner as for Cucumbers, but not so strong; and as soon as the first violent steam of the dung was over, some old rotten dung laid over the hot-bed to keep down the heat, or where it can be easily procured, neats dung is preferable for this purpose; then the plants should be turned out of the pots, and placed upon the bed as close together as possible, filling up the interstices between the plants with earth; afterward the plants must have air admitted to them every day; and if the heat of the bed is too great, the plants should be raised up, to prevent their roots being scorched; and if the bed is too cold, the sides of it should be lined with some hot dung: this first bed will bring the plants to flower by the latter end of February, or the beginning of March, by which time the heat of the bed will be spent, therefore another hot-bed should be prepared to receive the plants, which need not be so strong as the first; but upon the hot dung should be laid some neats dung about two inches thick, which should be equally spread and smoothed; this will prevent the heat of the bed from injuring the roots of the plants, upon this should be laid two inches of a loamy soil; when this has laid two days to warm, the plants should be taken out of the first hot-bed, and turned carefully out of the pots, preserving all the earth to their roots, and placed close together upon this new hot-bed, filling up the vacuities between the balls with loamy earth: the roots of the plants will soon strike out into this fresh earth, which will strengthen their flowers, and cause their fruit to set in plenty; and if proper care is taken to admit fresh air to the plants, and supply them properly with water, they will have plenty of ripe fruit in April, which will be full two months before their natural season.

The methods practised to retard this fruit, is first by planting them in the coldest part of the garden, where they may be as much in shade as possible, and the soil should be strong and cold; when there are such places in a garden, the fruit will be near a month later than in a warm situation; the next is to cut off all the flowers when they first appear, and if the season proves dry, to water them plentifully, which will cause them to put out a fresh crop of flowers; and if they are supplied with water, there will be a late crop of fruit, but these are not so well flavoured as those which ripen in their natural season.

But since the Alpine Strawberry has been introduced in the English gardens, there is little occasion for practising this method of retarding the fruit; because this sort will supply the table the whole summer, especially if care is taken to pull off the runners; and in dry seasons to water the plants, without which the blossoms will fall off, without producing fruit.

There are some persons so curious as to raise the plants from seeds, by which they have greatly improved some of the sorts; and if this was more practised, I am certain it would be found of singular service, where the fairest of the fruit of each kind are chosen. The seeds should be immediately sown when the fruit is eaten; the best way is to sow the seeds in pots, placing them in the shade.

In the spring of the year 1724, there was scarce any rain from February till about the middle of July, so that most of the Strawberries and Raspberries in the gardens near London, were burnt up, and came to no perfection; but upon plenty of rain falling in July, they recovered and put out plenty of flowers, which were succeeded by fruit, which ripened in September, when the markets of London were supplied with a great plenty of both those fruits at that season of the year.

FRANGULA. Tourn. Inst. R. H. 612. tab. 383. Rhamnus. Lin. Gen. Plant. 235. [is so called of frangendo, breaking, because of the brittleness of its wood.] Berry-bearing Alder.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut at the top into five segments, which are erect. The flower hath one petal, which is cut into five acute segments; these are placed between the segments of the empalement, into which they are inserted, but are shorter, and stand erect. It hath five stamina, which are the length of the petal, terminated by obtuse summits; in the center is situated a globular germen, supporting a slender style, crowned by an obtuse stigma. The germen afterward becomes a round berry, inclosing two plain roundish seeds.

This genus of plants is ranged in the second section of Tournefort's twenty-first class, which includes the trees and shrubs with a Rose flower, whose pointal turns to a berry. Dr. Linnæus has joined this genus with the Paliurus, Alaternus, and Ziziphus, to the Rhamnus, making them only species of one genus; but according to his own system, they should be separated to a great distance from Rhamnus, and be placed in his twenty-second class, because it hath male and female flowers on different plants; whereas it is placed in the first section of his fifth class, from the flower having five stamina and but one style.

The SPECIES are,

1. **FRANGULA** (*Alnus*) foliis ovato-lanceolatis glabris. *Frangula with oval, spear-shaped, smooth leaves.* Frangula, five alnus, nigra baccifera. Park. Theat. Black Berry-bearing Alder.
2. **FRANGULA** (*Latifolia*) foliis lanceolatis rugosis. *Frangula with rough spear-shaped leaves.* Frangula rugosiore & ampliore folio. Tourn. Berry-bearing Alder with a larger and rougher leaf.
3. **FRANGULA** (*Rotundifolia*) foliis ovatis nervosis. *Frangula with oval veined leaves.* Frangula montana pumila saxatilis, folio subrotundo. Tourn. Low mountain, rocky, berry-bearing Alder, with a round leaf.
4. **FRANGULA** (*Americana*) foliis oblongo-ovatis nervosis, glabris. *Frangula with oblong, oval, smooth veined leaves.* Frangula Americana foliis glabris. Dale. *American Berry-bearing Alder with smooth leaves.*

The first sort grows naturally in the woods in many parts of England, so is seldom planted in gardens; this rises with a woody stem to the height of ten or twelve feet, sending out many irregular branches, which are covered with a dark bark, and garnished with oval spear-shaped leaves, about two inches long, and one inch broad, having several transverse veins from the midrib to the sides, and stand upon short foot-stalks. The flowers are produced in clusters at the end of the former year's shoots, and also upon the first and second joints of the same year's shoot, each standing upon a short separate foot-stalk, on every side the branches; these are very small, of an herbaceous colour, and do not expand; they are succeeded by small round berries, which turn first red, but afterward black when ripe. The flowers appear in June, and the berries ripen in September; this stands in the Dispensary as a medicinal plant, but is seldom used.

The second sort hath larger rough leaves than the first. It grows naturally on the Alps and other mountainous parts of Europe, and is preserved in some gardens for the sake of variety.

The third sort is of humble growth, seldom rising above two feet high; this grows on the Pyrenean Mountains, and is seldom preserved unless in botanic

gardens for variety; it may be increased by laying down the branches, but must have a strong foil.

The fourth sort grows naturally in North America, from whence I received the seeds; this is pretty like the first sort, but the leaves are longer and broader; they are smooth, of a lucid green, and have many veins. The flowers are very like those of the first sort.

These shrubs are easily propagated by seeds, which should be sown as soon as they are ripe, and then the plants will come up the spring following; but if they are kept out of the ground till spring, the plants will not come up till the year after. When the plants come up, they must be kept clean from weeds till autumn, then they may be taken up and planted in a nursery in rows, two feet asunder, and at one foot distance in the rows; in this nursery they may remain two years, and may then be planted where they are to remain; they may also be propagated by layers and cuttings, but the seedling plants are best.

The fruit of the first sort is often brought into the markets of London, and sold for Buckthorn berries; of which cheat, all such as make syrup of Buckthorn should be particularly careful; they may be easily distinguished by breaking the berries, and observing how many seeds are contained in each, the berries of this tree having but two, and those of Buckthorn generally four seeds in each berry, and the juice of the latter dies paper of a green colour.

FRAXINELLA. See **DICTAMNUS**.

FRAXINUS. Lin. Gen. Plant. 1026. Tourn. Inst. R. H. 577. tab. 343. The Ash-tree; in French, *Frêne*.

The CHARACTERS are,

It hath hermaphrodite and female flowers on the same tree, and sometimes on different trees. The hermaphrodite flowers have no petals, but a small four-pointed empalement, including two erect stamina, which are terminated by oblong summits, having four furrows. In the center is situated an oval compressed germen, supporting a cylindrical style, crowned by a bifid stigma. The germen afterward becomes a compressed bordered fruit, shaped like a bird's tongue, having one cell, inclosing a seed of the same form. The female flowers are the same, but have no stamina.

This genus of plants is ranged in the second section of Linnæus's twenty-third class, which includes the plants which have flowers of different sexes on the same or different plants, which are fruitful.

The SPECIES are,

1. **FRAXINUS** (*Excelsior*) foliolis serratis, floribus apetalis. Lin. Sp. Plant. 1057. *Ash-tree whose smaller leaves are serrated, and flowers having no petals.* Fraxinus excelsior. C. B. P. 416. *The common Ash.*
2. **FRAXINUS** (*Rotundifolia*) foliolis ovato-lanceolatis serratis, floribus coloratis. *Ash-tree whose smaller leaves are oval, spear-shaped, and sawed, and the flowers coloured.* Fraxinus rotundior folio. C. B. P. 416. *Ash-tree with a rounder leaf, commonly called Manna Ash.*
3. **FRAXINUS** (*Ornus*) foliolis serratis, floribus coloratis. Lin. Sp. Plant. 1057. *Ash-tree whose smaller leaves are sawed, and flowers having petals.* Fraxinus humilior five altera Theophrasti, minore & tenuiore folio. C. B. P. 416. *Dwarf Ash of Theophrastus with smaller and narrower leaves.*
4. **FRAXINUS** (*Paniculata*) foliolis lanceolatis glabris, floribus paniculatis terminatricibus. *Ash-tree with smooth spear-shaped leaves, and flowers growing in panicles at the ends of the branches.* Fraxinus florifera botryoides. Mor. Præl. 265. *The flowering Ash.*
5. **FRAXINUS** (*Nova Anglia*) foliolis integerrimis, petiolis teretibus. Flor. Virg. 122. *Ash-tree with the small leaves entire, and taper foot-stalks.* Fraxinus ex Novâ Angliâ, pinnis foliorum in mucronem productioribus. Rand. Cat. Hort. Chelf. *New England Ash with long acute points to the wings of the leaves.*
6. **FRAXINUS** (*Caroliniana*) integerrimis petiolis teretibus fructu latiore. Prod. Leyd. 533. *Ash-tree with entire leaves and taper foot-stalks.* Fraxinus Caroliniana, latiore fructu. Rand. Cat. H. Chelf. *Carolina Ash with a broad fruit.*

The

The first sort is the common Ash-tree, which grows naturally in most parts of England, and is so well known as to need no description. The leaves of this sort have generally five pair of lobes, and are terminated by an odd one; they are of a very dark green, and their edges are slightly sawed. The flowers are produced in loose spikes from the side of the branches, which are succeeded by flat seeds, which ripen in autumn; there is a variety of this with variegated leaves, which is preserved in some gardens.

The second sort grows naturally in Calabria, and is generally supposed to be the tree from whence the manna is collected, which is an exudation from the leaves of the tree. The shoots of this tree are much shorter, and the joints closer together than those of the first sort; the small leaves are shorter, and deeper sawed on their edges, and are of a lighter green. The flowers come out from the side of the branches, which are of a purple colour, and appear in the spring before the leaves come out. This tree is of humble growth, seldom rising more than fifteen or sixteen feet high in England.

The third sort is a low tree, which rises about the same height as the second; the leaves of this sort are much smaller and narrower than those of the first, but are sawed on their edges, and are of the same dark colour. The flowers of this sort have petals, which are wanting in the common Ash.

The fourth sort was raised by the late Dr. Uvedale at Enfield, from seeds which were brought from Italy by Dr. William Sherard, where the trees grow naturally; but it was supposed to be a different sort from that mentioned by Dr. Morrison, in his *Præluia Botanica*, but by comparing them together they appear to be the same.

The leaves of this sort have but three or four pair of lobes (or small leaves) which are short, broad, and smooth, of a lucid green, and irregularly sawed on the edges; the midrib of the great leaf is jointed, and swelling where the leaves come out. The flowers grow in loose panicles at the end of the branches; these are most of them male, having two stamina in each, but no germen or style; they are of a white herbaceous colour, and appear in May. As this sort very rarely produces seeds in England, it is propagated by grafting or budding it upon the common Ash.

The fifth sort was raised from seeds, which were sent from New England in the year 1724, by Mr. Moore. The leaves of this tree have but three, or at most but four pair of lobes (or small leaves) which are placed far distant from each other, and are terminated by an odd lobe, which runs out into a very long point; they are of a light green and entire, having no serratures on their edges: this tree shoots into strong irregular branches, but doth not grow to a large size in the trunk. It is propagated by grafting it upon the common Ash.

The sixth sort was raised from seeds which were sent from Carolina in the year 1724, by Mr. Catesby. The leaves of this sort hath seldom more than three pair of lobes, the lower being the least, and the upper the largest; these are about five inches long and two broad, of a light green colour, and slightly sawed on their edges; the foot-stalk, or rather the midrib, of the leaves is taper, and has short downy hairs; the seeds are broader than those of the common Ash, and are of a very light colour. As this sort hath not yet produced seeds in England, it is propagated by grafting it upon the common Ash.

These trees are now propagated in plenty in the nurseries for sale, as there has been of late years a great demand for all the hardy sorts of trees and shrubs, which will live in the open air; but all those trees which are grafted upon the common Ash, are not so valuable as those which are raised from seeds, because the stock grows much faster than the grafts; so that the lower part of the trunk, so far as the stock rises, will often be twice the size of the upper; and if the trees stand much exposed to the wind, the grafts are frequently broken off to the stock, after they are

grown to a large size, which is a great disappointment to a person after having waited several years, to see their trees suddenly destroyed. Beside, if the wood of either of the sorts is valuable, it can be of little use when the trees are so raised.

The fourth sort is generally planted for ornament, the flowers making a fine appearance when they are in beauty, for almost every branch is terminated by a large loose panicle; so that when the trees are large, and covered with flowers, they are distinguishable at a great distance.

All the other sorts serve to make a variety in plantations, but have little beauty to recommend them; and as their wood seems to be greatly inferior to that of the common Ash, so there should be few of these planted, because they will only fill up the space where better trees might grow.

The common Ash propagates itself in plenty by the seeds which scatter in the autumn, so that where the seeds happen to fall in places where cattle do not come, there will be plenty of the plants come up in the spring; but where any person is desirous to raise a quantity of the trees, the seeds should be sown as soon as they are ripe, and then the plants will come up the following spring; but if the seeds are kept out of the ground till the spring, the plants will not come up till the year after, which is the same with all the sorts of Ash; that when any of their seeds are brought from abroad, as they seldom arrive here before the spring, the plants must not be expected to appear till the next year; therefore the ground should be kept clean all the summer where they are sown, and not disturbed, lest the seeds should be turned out of the ground, or buried too deep to grow; for many persons are too impatient to wait a year for the growth of seeds, so that if they do not come up the first year, they dig up the ground, and thereby destroy the seeds.

When the plants come up, they must be kept clean from weeds during the summer; and if they make good progress in the seed-bed, they will be fit to transplant by the autumn; therefore there should be some ground prepared to receive them, and as soon as their leaves begin to fall, they may be transplanted. In taking them up, there should be care taken not to break or tear off their roots; to prevent which, they should be taken up with a spade, and not drawn up, as is frequently practised; for as many of the plants which rise from seeds will out-strip the others in their growth, so it is frequently practised, to draw up the largest plants, and leave the smaller to grow a year longer before they are transplanted; and to avoid hurting those which are left, the others are drawn out by hand, and thereby many of their roots are torn off or broken; therefore it is much the better way to take all up, little or big together, and transplant them out, placing the larger ones together in rows, and the smaller by themselves. The rows should be three feet asunder, and the plants a foot and a half distance in the rows; in this nursery they may remain two years, by which time they will be strong enough to plant where they are to remain; for the younger they are planted out, the larger they will grow; so that where they are designed to grow large, they should be planted very young; and the ground where the plants are raised, should not be better than that where they are designed to grow; for when the plants are raised in good land, and afterward transplanted into worse, they very rarely thrive; so that it is much the best method to make the nursery upon a part of the same land, where the trees are designed to be planted, and then a sufficient number of trees may be left standing upon the ground, and these will out-strip those which are removed, and will grow to a larger size.

Where people live in the neighbourhood of Ash-trees, they may supply themselves with plenty of self-sown plants, provided cattle are not suffered to graze on the land, for they will eat off the young plants, and not suffer them to grow; but where the seeds fall in hedges, or where they are protected by bushes, the

F R E

plants will come up and thrive; and in these hedges the trees frequently are permitted to grow till they have destroyed the hedge, for there is scarce any tree so hurtful to all kinds of vegetables as the Ash, which robs every plant of its nourishment within the reach of its roots, therefore should never be suffered to grow in hedge rows; for they not only kill the hedge, but impoverish Corn, or whatsoever is sown near them. Nor should Ash-trees be permitted to grow near pasture grounds, for if any of the cows eat of the leaves or shoots of the Ash, all the butter which is made of their milk will be rank and of no value; which is always the quality of the butter which is made about Guildford, Godalmin, and some other parts of Surry, where there are Ash-trees growing about all their pastures, so that it is very rare to meet with any butter in those places which is fit to eat; but in all the good dairy countries, they never suffer an Ash-tree to grow.

If a wood of these trees is rightly managed, it will turn greatly to the advantage of its owner; for by the under-wood, which will be fit to cut every seven or eight years, for poles or hoops, there will be a continual income more than sufficient to pay the rent of the ground, and all other charges; and till there will be a stock preserved for timber, which in a few years will be worth forty or fifty shillings per tree.

This timber is of excellent use to the wheelwright and cartwright, for ploughs, axle-trees, wheel-rings, harrows, bulls, oars, blocks for pulleys, and many other purposes.

The best season for felling of these trees is from November to February; for if it be done either too early in autumn, or too late in the spring, the timber will be subject to be infested with worms, and other insects; but for lopping pollards, the spring is preferable for all soft woods.

FREEZING is the fixing of a fluid, or the depriving it of its natural mobility by the action of cold; or it is the act of converting a fluid substance into a firm, coherent, rigid one, called ice.

The principal phenomena of freezing are,

1st, That Water being dilated or rarefied, and all fluids, oil excepted, i. e. in freezing, take up more space, and are specifically lighter than they were before. That the bulk and dimensions of water are increased by freezing, is found by many experiments, and it may not be improper here to take notice of the process of nature.

A glass vessel then, I A, full of water to A, being immersed in a vessel of water mixed with salt G H K L, the water presently rises from D to C; which seems owing to the sudden constriction of the vessel, hastily plunged into so cold a medium: soon after, from the point C, it continually descends condensing, till it arrives at the point F; where, for some time, it seems to remain at rest: but it soon recovers itself, and begins to expand, rising from F to E, and from thence soon after, by one violent leap, mounts to B; and here the water in I is immediately seen all thick and cloudy, and, in the very instant of this leap, is converted into ice. Add, that while the ice is growing harder, and some of the water near the neck of the vessel I is freezing, the flux of the water is continued above B towards A, and at length runs out at the vessel.

2dly, That they lose not only of the specific, but also of their absolute gravity, by freezing; so that when they are thawed again, they are found considerably lighter than before.

3dly, That frozen water is not quite so transparent as when it was liquid, and that bodies do not perspire so freely through it.

4thly, That water, when frozen, evaporates almost as much as when fluid.

5thly, That water does not freeze in vacuo, but requires the presence and contiguity of air.

F R E

6thly, That water which has been boiled, does not freeze so readily as that which has not.

7thly, That water, being covered over with a surface of oil of Olives, does not freeze so readily as it does without it; and that nut oil absolutely preserves it under a strong frost, when Olive oil will not.

8thly, That spirit of wine, nut oil, and oil of turpentine, do not freeze at all.

9thly, That the surface of the water, in freezing, appears all wrinkled; the wrinkles being sometimes in parallel lines, and sometimes like rays proceeding from a center to the circumference.

The theories of freezing, or the method of accounting for these phenomena, are very many.

The chief principles that different authors have gone upon, are, either that some foreign matter is introduced within the pores of the fluid, by means of which it is fixed, its bulk increased, &c.

Or that some matter which was naturally contained in the fluid is now expelled, by reason of the absence of which, the body becomes fixed.

Or that there is some alteration produced in the texture or form, either of the particles of the fluid itself, or of something that is contained within it.

To some one of these principles all the systems of freezing are reducible.

The Cartesians explicate freezing by the recess or going out of the ethereal matter from the pores of the water, or other liquor; which being once done, the finer parts are too small and flexible to keep the long, slender, and eel-like particles of water fluent, or in the form of a liquor.

But the Corpuscularians, or Gassendists, ascribe the freezing of water, with more probability, to the ingress of multitudes of cold or frigorific particles, as they call them; which, entering the liquor in swarms, and dispersing themselves every way through it, crowd into the pores of the water, and hinder the wonted agitation of its parts, and wedge it up, as it were, into the hard or consistent body of ice; and from hence proceeds its increase of dimensions, coldness, &c.

That ice is specifically lighter than the water out of which it is by freezing made, is certain by its swimming in it; and that this lightness of ice proceeds from those numerous bubbles which are produced in it by its congelation, is equally plain; but how those bubbles come to be generated in freezing, and what substance they contain in them, if they are not quite empty, is an inquiry of great importance; and, perhaps, if discovered, may contribute much to the understanding the nature of cold.

Mr. Hobbes will have it common air, which, intruding into the water in congelation, entangles itself with the particles of the fluid, prevents their motion, and produces those numerous bubbles, thus expanding its bulk, and rendering it specifically lighter.

But, in answer to this, no such ingress of air into water appears in its coagulation; and that it does not get into frozen oil is plain, because that body is condensed by being frozen.

And Mr. Boyle has also shewn, by undoubted experiments, that water will freeze in vessels hermetically sealed; and in brass bodies or vessels closely stopped, and into which the air can have no ingress, hath yet been turned into ice, abounding with these bubbles as numerous as those frozen in the open air.

He also has proved by experiment, that water kept a while in the exhausted receiver, till all its bubbles were emerged and gone, being afterwards turned into ice by a freezing mixture, the ice had scarce any bubbles in it; whence it is plain, that these bubbles are filled with some matter which is within the water, if they are filled with any thing. But he proves also, by plain experiments, that they have none, or exceedingly little, true elastic air contained in them.

Others, and those of the greatest number, are of opinion, that the freezing matter is a salt; and they argue that an excess of cold will render water torpid, but never congeal it without salt: they say that those

F R E

particles that are the chief cause of freezing are saline, mixed in a due proportion, congelation bearing a near relation to crystallization.

This salt is supposed to be of the nitrous kind, and to be furnished by the air, which is generally found to abound in nitre.

It is indeed no difficult matter, to account for the particles of nitre preventing the fluidity of water. These particles are supposed to be so many rigid pointed spicula, which are easily impelled or driven into the stamina or globules of water; which, by this means, becoming variously mingled and entangled with it, do, by degrees, weaken and destroy the motion of it.

The reason that this effect arises only in severe winter weather, is, that it is then only that the retracting action of the nitrous spicula is more than equal to the power or principle by which the fluid is otherwise kept in motion, or disposed for motion.

Several experiments of artificial freezing support this opinion.

For if you mix a quantity of common saltpetre with snow, or ice pulverized, and dissolve the mixture in the fire, and then immerse a tube full of water in the solution; the water, that part of it next the mixture, will freeze presently, even in a warm air.

Whence they argue, that the spicula of the salt are driven through the pores of the glass, and mixed with the water, by the gravity of the mixture, and of the incumbent air; for that it is evident, that the salt has this effect, inasmuch as it is certainly known, that the particles of water cannot find their way through the pores of the glass.

In these artificial freezings, in whatever part the mixture is applied, there is presently a skin or lamina of ice produced, whether at the top, bottom, or sides, by reason that there is always a stock of saline corpuscles, sufficient to overpower the particles of fire; but natural congelations are confined to the top of the water, where the last most abounds.

But this system is opposed by the author of the *Nouvelle Conjecture pour expliquer la Nature de la Glace*, who objects, that it does not appear, that the nitre always enters the composition of ice; but if it did, it would fall short of accounting for some of the principal effects; as,

How should the particles of nitre, by entering the pores of the water, and fixing the parts, cause the water to dilate, and render it specifically lighter? They should naturally augment its weight.

This and some other difficulties, shew the necessity of a new theory; and therefore the ingenious author advances this which follows, which seems to solve the phenomena in a manner that is more easy and simple, as not depending upon the admission or extrusion of any heterogeneous matter.

The water freezes in the winter only, because its parts, then being more closely joined together, mutually embarrass one another, and lose all the motion they had; and that the air, or rather an alteration in the spring and force of the air, is the cause of this closer union of water.

It is evident from experiment, that there are an infinite number of particles of gross air interspersed among the globules of water; and it is allowed, that each particle of air has the virtue of a spring; and hence this author argues, that the small springs of gross air, mixed with water, have more force in cold winter weather, and do then unbend themselves more, than at other times. Hence those springs thus unbending themselves on one side, and the external air continuing to press the surface of the water on the other, the particles of the water, being thus constricted and locked up together, must lose their motion and fluidity, and form a hard, consistent body, till a relaxation of the spring of the air, from an increase of heat, reduce the particles to their old dimensions, and leave room for the globules to flow again.

But this system seems to be built upon a false prin-

F R E

ciple, for the spring or elasticity of the air is not increased by cold, but diminished; air condenses by cold, and expands itself by heat; and it is demonstrable in pneumatics, that the elastic force of expanded air is to that of the same air condensed, as the bulk when rarefied is to its bulk when condensed.

Indeed, some authors, in order to account for the increase of the bulk and dimension of the specific gravity of frozen water, have advanced as follows, viz. That the aqueous particles, in their natural state, were nearly cubes, and so filled their space without the interposition of many pores; but that they are changed from cubes to spheres, by congelation; from whence it will necessarily follow, that there must be a great deal of empty space between them.

But, in opposition to this hypothesis, the nature of fluidity and firmness easily suggests, that spherical particles are much properer to constitute a fluid than cubical ones, and less disposed to form a fixed than cubic one.

But after all, in order to come to a consistent theory of freezing, we must either have recourse to the frigorific matter of the Corpuscularians, considered under the new light and advantages of the Newtonian philosophy, or to the ethereal matter of the Cartesians, under the improvements of *Monf. Gauteron*.

The true cause of freezing, or the congelation of water into ice, say the former, seems plainly to be the introduction of the frigorific particles into the pores or interstices between the particles of the water, and by that means getting so near them, as to be just within the spheres of one another's attracting force, and then they must cohere into one solid or firm body; but heat afterwards separating them, and putting them into various motions, breaks this union, and separates the particles so far from one another, that they get out of the distance of the attracting force, and into the verge of the repelling force, and then the water re-assumes its fluid form.

Now, that cold and freezing proceed from some substance of a saline nature floating in the air, seems probable from hence:

That all salts, and more eminently some particular ones, do prodigiously increase the force and effects of cold, when mixed with snow or ice. It is also evident, that all saline bodies produce a stiffness and rigidity in the parts of those bodies into which they enter.

It appears, by microscopical observations upon salts, that the figure of some salts, before they shoot into masses, are thin, double wedged, like particles which have abundance of surface, in respect to their solidity; and is the reason why they swim in water, when once raised in it, though specifically heavier.

These small points, getting into the pores of the water, whereby they are also, in some measure, suspended in the winter time, when the heat of the sun is not ordinarily strong enough to dissolve the salts into a fluid, to break their points, and to keep them in perpetual motion, being less disturbed, are at more liberty to approach one another; and, by shooting into crystals of the form above-mentioned, do, by both their extremities, insinuate themselves into the pores of the water, and by that means freeze it into a solid form. And it is apparent, that the dimensions of water are increased by freezing, the particles of it being kept at some distance from one another, by the intervention of the frigorific matter.

But besides this, there are many little volumes, or small particles of air, included at several distances, both in the pores of the watery particles, and in the interstices formed by their spherical figure. Now, by the insinuation of the crystals, the volumes of air are driven out of the watery particles, and many of them uniting, form larger volumes, which thereby have a greater force to expand themselves than when they are dispersed; and so both enlarge the dimensions, and lessen the specific gravity of water thus congealed into ice.

And hence (says *Dr. Cheyne*, from whom this last account is taken) we may guess at the manner how water,

ter,

F R E

ter, impregnated with salts, sulphurs, or earths, which are not easily dissolvable, may form itself into metals, minerals, gums, and other fossils; the parts of these mixtures becoming a cement to the particles of water, or getting into their pores, change them into these different substances.

For the second: as an ethereal matter or medium is generally allowed to be the cause of the motion of fluids, and as the air itself has all its motion from the same principle, it follows, that all fluids must remain in a state of rest or fixity, when that matter loses of its necessary force. And consequently, the air being less warmed in the winter time, by reason of the obliquity of the sun's rays, is more dense and fixed in winter than any other season of the year.

But farther: it is evident, from divers experiments, that the air does contain a salt which is supposed to be of the nature of nitre. If this be granted, and the density of the air allowed, it will follow, that the particles of this nitre must likewise be brought nearer together, and thickened by the condensation of the air; as on the contrary, a rarefaction of the air, and an augmentation of its fluidity, must divide and separate them.

And if the same happens to all liquors that have imbibed or dissolved any salt, if the warmth of the liquid keep the salt exactly divided, and if the coolness of a cellar, or of ice, cause the particles of the dissolved salt to approach, run into each other, and shoot into crystals; why should the air, which is allowed to be a fluid, be exempt from the general law of fluids?

It is true, that the nitre of the air, being grosser in cold weather than in hot, must have a less velocity; but still the product of its augmented mass into the velocity that remains, will give it a greater momentum, or quantity of motion. Nor is there any thing farther required to make this salt act with greater force against the parts of fluids, and this may probably be the cause of the great evaporation in frosty weather.

This aerial nitre must necessarily promote the concretion of liquids; for it is not the air, nor yet the nitre that it contains, which gives the motion to fluids; it is the ethereal medium, therefore a diminution of the motion of rest arises from the diminution of that force.

Now the ethereal matter, which in the winter time is weak enough, must still lose more of its force by its action against air condensed, and loaded with large particles of salt. It must therefore lose of its force in cold weather, and become less disposed to maintain the motion of the fluids.

In fine, the air, during frost, may be esteemed like the ice impregnated with salt wherewith liquors are iced in summer time. It is very probable that these liquors freeze by reason of a diminution of the motion of the ethereal medium, by its acting against the ice and salt together, and the air is not able to prevent its concretion by all its scorching heat.

The air (says Mr. Boyle) being a fluid as well as water, and impregnated with salts of different kinds, it is not improbable, that what happens in water impregnated with such salts, may also happen in the air.

Two proper quantities of different salts being dissolved in hot water, they floated undistinguishably in it, and retained a capacity to act in conjunction upon several occasions; yet when the liquor becomes cold, the saline particles of one kind being no longer agitated by a due degree of heat, shot into crystals; and, losing their fluidity and motion, visibly separated themselves from the other, which still continued fluid in the liquor, and capable of acting separately.

We have divers accounts in the Philosophical Transactions, of a freezing rain which fell in the west of England in December 1672. This rain, as soon as it touched any thing above the ground, as a bough, or the like, immediately settled into ice; and, by multiplying and enlarging the icicles broke all down with its weight; the rain that fell on the snow im-

F R I

mediately froze into ice, without sinking into the snow at all.

It made an incredible destruction of trees beyond any thing in all history. A certain gentleman weighed a sprig of an Ash-tree of just three quarters of a pound, the ice which was on it weighed 16 pounds; that some persons were frightened with the noise in the air, till they understood that it was the clatter of icy boughs dashed against each other.

Dr. Beale remarks, that there was no considerable frost observed on the ground during the whole time; whence he concludes, that a frost may be very fierce and dangerous on the tops of some hills and plains, while in other places it keeps at two, three, or four feet distance above the ground, rivers, lakes, &c. and may wander about very furious in some places, and remiss in others not far off. The frost was followed by glowing heats, and a wonderful forwardness of flowers and fruits. The effects of freezing vegetables, is farther explained under the article of Frost.

FRITILLARIA. Lin. Gen. Plant. 372. Tourn. Inst. R. H. 376. tab. 201. Corona Imperialis. Tourn. Inst. R. H. 372. tab. 197, 198. Fritillary, or Chequered Tulip and Crown Imperial.

The CHARACTERS are,

The flower hath no empalement; it hath six oblong petals, is bell-shaped, and spreading at the base; in the hollow, at the base of each petal, is situated a nectarium; the flower hath six stamina standing near the style, which are terminated by oblong four-cornered summits. In the center is situated an oblong three-cornered germen, supporting a single style which is longer than the stamina, crowned by a spreading obtuse stigma. The germen afterward becomes an oblong capsule with three lobes having three cells, which are filled with flat seeds, ranged in a double order.

The capsule of Fritillaria is oblong and smooth, but that of Corona Imperialis hath acute borders, or membranaceous wings.

This genus of plants is ranged in the first section of Linnæus's sixth class, which includes the plants which have six stamina in their flowers, and but one style.

These two genera of Fritillary and Crown Imperial, have been always separated, till Dr. Linnæus joined them together; indeed by their flowers they may be properly enough placed in the same genus; but, if their fruit may be allowed as a characteristic note, they should be separate; however, as this new system is generally received, I shall, in compliance with the present taste, join them together.

The SPECIES are,

1. **FRITILLARIA (Melagris)** foliis linearibus alternis, floribus terminalibus. *Fritillary with narrow leaves placed alternate, and flowers terminating the stalk.* Fritillaria præcox, purpurea, variegata. C. B. P. 64. *Early, purple, variegated, chequered Tulip.*
2. **FRITILLARIA (Aquitana)** foliis infimis oppositis. Hort. Cliff. 81. *Fritillary whose lower leaves are opposite.* Fritillaria Aquitana, flore luteo obscuro. Swert. Floril. *Aquitain chequered Tulip, with an obscure yellow flower.*
3. **FRITILLARIA (Nigra)** floribus adscendentibus. *Fritillary with flowers growing above each other.* Fritillaria nigra. Lob. Adver. 2. 496. *Black chequered Tulip.*
4. **FRITILLARIA (Lutea)** foliis lanceolatis, caule unifloro maximo. *Fritillary with spear-shaped leaves, and one large flower on each stalk.* Fritillaria lutea maxima Italica. Park. Parad. 43. *Largest yellow Italian Fritillary.*
5. **FRITILLARIA (Umbellata)** floribus umbellatis. *Fritillary with flowers growing in umbels.* Fritillaria umbellifera. C. B. P. 64. *Umbellated chequered Tulip.*
6. **FRITILLARIA (Persica)** racemo nudiusculo, foliis obliquis. Hort. Upsal. 82. *Fritillary with a naked spike of flowers and oblique leaves.* Lilium Persicum. Dod. Pempt. 220. *The Persian Lily.*
7. **FRITILLARIA (Racemosa)** floribus racemosis. *Fritillary with flowers growing in bunches.* Fritillaria ramosa, seu lilium Persicum minus. Mor. Hort. Reg. Blef. *Branching Fritillary, or smaller Persian Lily.*

8. FRI-

8. *Fritillaria (Imperialis)* racemo comofo infernè nudo, foliis integerrimis. Lin. Hort. Upsal. 82. *Fritillary with a tufted bunch of leaves over the flowers, which is naked below, and entire leaves.* Corona Imperialis. Dod. Pempt. 202. *Crown Imperial.*

9. *Fritillaria (Regia)* racemo comofo infernè nudo, foliis crenatis. Lin. Sp. Plant. 303. *Fritillary with a tufted bunch of leaves over the flowers, which is naked below, and crenated leaves.* Corona regalis lilii folio crenato. Hort. Elth. 110. *Royal Crown with a crenated Lily leaf.*

10. *Fritillaria (Autumnalis)* racemo infernè nudo, foliis oblongis mucronatis. *Fritillary with a naked stalk, and oblong pointed leaves.*

The first sort grows naturally in Italy, and other warm parts of Europe; and from the seeds of this there have been great varieties raised in the gardens of the florists, which differ in the size and colour of their flowers; and as there are frequently new varieties produced, so it would be to little purpose to enumerate those which are at present in the English and Dutch gardens, which amount to a great number in the catalogues of the Dutch florists, who are very fond of any little distinction, either in the colour or shape, to enlarge their lists.

The sorts which are here enumerated, I think may be allowed as distinct species, notwithstanding Dr. Linnæus has reduced them to five; for I have raised many of all the sorts from seed, which have constantly produced the same as the seeds were taken from, and have only differed in the colour or size of the flowers; for the sort with broad leaves produced the same sort again, and the umbellated and spiked sorts produced the same, though there are several varieties in the colours of their flowers.

The first hath a round compressed root, in shape like that of Cornflag, but is of a yellowish white colour; the stalk rises about fifteen inches high, having three or four narrow long leaves placed alternately, and the top is divided into two slender foot-stalks which turn downward, each sustaining one bell-shaped inverted flower, composed of six petals, which are chequered with purple and white like a chess-board; and in the center is situated a germen supporting one style, crowned by a trifid stigma; the six stamina stand about the style, but are shorter. At the bottom of each petal there is a cavity, in which is situated a nectarium, filled with a sweet liquor; after the flower is fallen, the germen swells to a pretty large three-cornered blunt capsule, and then the foot-stalk is turned and stands erect; when the seeds are ripe, the capsule opens in three parts and lets out the flat seeds, which were ranged in a double order. The flowers of this appear the latter end of March or beginning of April, and the seeds are ripe in July. There is a variety of this with a double flower.

The second sort grows naturally in France; the leaves of this are broader, and of a deeper green than the former; the lower leaves are placed opposite, but those above are alternate; the stalk rises a foot and a half high, and is terminated by two flowers of an obscure yellow colour, which spread more at the brim than those of the first sort, but are turned downward in the same manner. This flowers three weeks after the first. There is a variety of this with greenish flowers, which grows naturally in some parts of England.

The third sort seldom rises more than a foot high, the leaves are narrow like those of the first sort, but are shorter; each stalk is terminated by three or four flowers, which arise above each other; they are of a very dark purple, chequered with yellowish spots. This flowers in April, about the same time with the second.

The fourth sort rises about a foot high, the stalk is garnished with spear-shaped leaves four inches long and one broad, of a grass-green colour; these are sometimes placed opposite, but are generally alternate; the stalk is terminated by one large bell-shaped flower of a yellowish colour, chequered with light

F R I

purple. This sort flowers about the same time as the first. There are two or three varieties of this, which differ in the size and colour of their flowers and the breadth of their leaves, but retain their specific difference, so as to be easily distinguished from the other sorts.

The fifth sort rises a foot and a half high; the stalk is garnished with shorter and broader leaves than the first sort, which are of a grayish colour; the flowers are produced round the stalks like those of the Crown Imperial; they are of a dark purple colour, chequered with a yellowish green. This flowers about the same time with the second sort.

The sixth sort is commonly called the Persian Lily, and is supposed to grow naturally in Persia, but has been long cultivated in the English gardens; the root of this sort is round and large, the stalk rises three feet high; the lower part of it is closely garnished with leaves which are three inches long, and half an inch broad, of a gray colour, standing on every side of the stalks, but are twisted obliquely; the flowers grow in a loose spike at the top of the stalk, forming a pyramid; they are shaped like those of the other species, but are much shorter, and spread wider at their brims, and are not bent downward like those. They are of a dark purple colour, and appear in May, but are seldom succeeded by seeds in England, so are only propagated by offshoots.

The seventh sort hath a much shorter stalk than the last, but is garnished with leaves like those, only they are smaller; the stalks branch out at the top into several small foot-stalks, each sustaining one dark coloured flower. This is commonly called the small Persian Lily, from its resemblance to the former sort. These plants are propagated either by seeds, or offshoots from the old roots; by the first of which methods new varieties will be obtained, as also a larger stock of roots in three years, than can be obtained in twenty or thirty years in the latter method: I shall therefore first treat of their propagation by seeds.

Having provided yourself with some good seeds, saved from the fairest flowers, you must procure some shallow pans or boxes, which must have some holes in their bottoms to let out the moisture; these you should fill with light fresh earth, laying a few pot-sheards over the holes, to prevent the earth from stopping them; then, having laid the earth very level in the boxes, &c. you must sow the seeds thereon pretty thick, covering it with fine sifted earth a quarter of an inch thick. The time for sowing the seed is about the beginning of August, for if it be kept much longer out of the ground it will not grow; then place the boxes or pans where they may have the morning sun until eleven o'clock, observing, if the season proves dry, to water them gently, as also to pull up all weeds as soon as they appear; for if they are suffered to remain until they have taken deep root into the earth, they would draw the seeds out of the ground whenever they are pulled up. Toward the latter end of September you should remove the boxes, &c. into a warmer situation, placing them close to a hedge or wall exposed to the south; if they are sown in pots, these should be plunged into the ground, but they are best in tubs; these should be covered in severe frost. In this situation they may remain until the middle of March, by which time the plants will be come up an inch high; you must therefore remove the boxes, as the weather increases hot, into a more shady situation; for while the plants are young, they are liable to suffer by being too much exposed to the sun: and in this shady situation they may remain during the heat of the summer, observing to keep them clear from weeds, and to refresh them now and then with a little moisture; but be careful not to give them much water after their leaves are decayed, which would rot their roots. About the beginning of August, if the roots are very thick in the boxes, you should prepare a bed of good light fresh earth, which must be levelled very even, upon which you should spread the earth in the boxes in which

which the small roots are contained, equally covering it about one fourth of an inch thick with the same fresh earth: this bed should be situated in a warm position; but not too close to hedges, walls, or pales, which would cause their leaves to be long and slender, and make the roots weaker than if placed in a more open exposure.

In this bed they may remain until they flower, which is generally the third year from sowing; at which time you should put down a mark to the roots of all such as produce fair flowers, that at the time of taking them out of the ground (which ought to be soon after their green leaves are decayed) they may be selected into a bed amongst your old roots of this flower, which, for their beauty, are preserved in the best gardens; but the other less valuable flowers may be planted in the borders of the parterre-garden for their variety, where, being intermixed with other flowers of different seasons, they will make a good appearance.

The fine sorts of this flower should remain undisturbed three years, by which time they will have produced many offsets; and should be taken up when their leaves are decayed, and planted into a fresh bed, taking such of their offsets as are large enough to produce flowers to plant in the flower-garden; but the smaller roots may be planted into a nursery-bed, until they have obtained strength enough to flower; but you must never suffer these roots to lie out of the ground when you remove them, but plant them again immediately, otherwise they will perish.

During these three years which I have advised the roots to remain in the beds, the surface of the earth should be stirred every autumn with a trowel; observing not to go so deep as to bruise the root, and at the same time lay a thin cover of very rotten dung or tanners bark upon the surface of the beds; which, being washed into the ground, will cause the flowers to be larger, as also the roots to make a greater increase: you must also observe to keep them constantly clear from weeds, and those roots which you would preserve with care, should not be suffered to seed.

When a stock of good flowers are obtained, they may be preserved and increased in the same manner as other bulbous rooted flowers, which is by offsets sent out from their roots, which should be taken off every other year from the finest sorts; but the ordinary flowers may remain three years undisturbed, in which time they will have multiplied so much, as that each root will have formed a cluster; so that if they are left longer together, the roots will be small, and the flowers very weak; therefore, if these are taken up every other year, the roots will be the stronger. These roots may be treated in the same manner as Tulips, and other bulbous rooted flowers, with this difference only, that the roots will not bear to be kept out of the ground so long; therefore, if there should be a necessity for keeping them out of the ground any time, it will be best to put the roots into sand to prevent their shrinking.

As these flowers come but early in the spring, they make a pretty appearance in the borders of the pleasure-garden, where they are planted in small clumps; for when they stand single in the borders, they make but a poor figure.

The eighth sort is the Crown Imperial, which is now very common in the English gardens. This grows naturally in Persia, from whence it was first brought to Constantinople, and about the year 1570, was introduced to these parts of Europe; of this flower there are a great variety now preserved in the gardens of florists, but as they have been produced accidentally from seeds, they are but one species; however, for the satisfaction of the curious, I shall here mention all the varieties which have come to my knowledge.

1. The common Crown Imperial; this is of a dirty red-colour.

2. The yellow Crown Imperial; this is of a bright yellow.

3. The bright red Crown Imperial, called Fusai.

4. The pale yellow Crown Imperial.

5. The yellow striped Crown Imperial.

6. The large flowering Crown Imperial.

7. The broad leaved late red Crown Imperial.

8. The double and triple crowned Imperial Crown.

9. The double red Crown Imperial.

10. The double yellow Crown Imperial.

11. The silver striped leaved Crown Imperial.

12. The yellow striped leaved Crown Imperial.

There are some few other varieties which are mentioned in the catalogues of the Dutch florists, but their distinctions are so minute, that they are not distinguishable, so I shall pass them over, as those here inserted are all that I have seen growing either in England or Holland, which deserved any distinction.

The Crown Imperial hath a large round scaly root of a yellow colour, and a strong odour of a fox; the stalk rises to the height of four feet or upward; it is strong, succulent, and garnished two-thirds of the length on every side, with long narrow leaves ending in points, which are smooth and entire; the upper part of the stalk is naked, a foot in length; then the flowers come out all round the stalk upon short foot-stalks, which turn downward, each sustaining one large, spreading, bell-shaped flower, composed of six spear-shaped petals; at the base of each petal is a pretty large cavity, in which is situated a large white nectarium, filled with a mellow liquor. In the center of the flower is fixed a three-cornered oblong germen, upon which rests the single style; which is the length of the petals, and is crowned by a spreading obtuse stigma; round the style there are six awl-shaped stamina which are shorter than the style, and are terminated by oblong four-cornered summits. These flowers hang downward; and above them rises a spreading tuft of green leaves, which are erect, and from between these come out the foot-stalks of the flowers: when the flowers decay, the germen swells to a large hexagonal capsule, shaped like a water-mill; having six cells, which are filled with flat seeds. This plant flowers the beginning of April, and the seeds are ripe in July.

The sort with yellow flowers, that with large flowers, and those with double flowers, are the most valuable; but that which hath two or three whorls of flowers above each other, makes the finest appearance; though this seldom produces its flowers after this manner the first year after removing, but the second and third year after planting, the stalks will be taller, and frequently have three tier of flowers; one above another, which is called the Triple Crown. The stalks of this sort frequently run flat and broad, when they produce a greater number of flowers than usual; but this is only a luxuriancy of nature, not constant, though many of the writers have mentioned it as a particular variety.

As this is one of the earliest tall flowers of the spring; it makes a fine appearance in the middle of large borders; at a season when such flowers are much wanted to decorate the pleasure-garden: but the rank fox-like odour which they emit, is too strong for most people, so hath rendered the flowers less valuable than they would have been; for there is something very pleasing in the sight of them at a distance, so that were it not for the offensive smell of the leaves and flowers, it would be more frequently seen in all gardens for pleasure.

This may be propagated by seeds, or offsets from the root; the first is too tedious for most of the English florists, because the plants so raised, are six or seven years before they flower; but the Dutch and Flemish gardeners, who have more patience, frequently raise them from seeds; so get some new varieties, which rewards their labour. The method of propagating these flowers from seeds, being nearly the same as for the Tulip, the reader is desired to turn to that article, where there are full directions for performing it.

The common method of propagating them here, is by offsets sent out from the old roots, which will

flower strong the second year after they are taken from the roots; but in order to have plenty of these, the roots should not be transplanted oftener than every third year, by which time each root will have put out several offsets, some of which will be large enough to flower the following year, so may be planted in the borders of the flower-garden, where they are to remain; and the smaller roots may be planted in a nursery-bed, to grow a year or two according to their size; therefore they should be sorted, and the smallest roots planted in a bed together, which should remain there two years, and the larger by themselves to stand one year, by which time they will have acquired strength enough to flower, so may then be removed into the pleasure-garden.

The time for taking up these roots is in the beginning of July, when their stalks will be decayed; and they may be kept out of the ground two months, but they should be laid single in a dry shady room, but not in heaps, or in a moist place, which will cause them to grow mouldy and rot. The offsets should be first planted, for as these are small, they will be apt to shrink if they are kept long out of the ground.

As the roots are large, they must not be planted too near other flowers; and when they are planted in beds by themselves, they should not be nearer than a foot and a half in the rows, and two feet row from row; they should be planted six inches deep at least, especially the strong roots: they delight in a light soil, not too wet, nor very full of dung; therefore, if any dung is laid upon the borders where they are planted, it should be buried pretty deep, so as to be two or three inches below the roots.

The ninth and tenth sorts grow naturally at the Cape of Good Hope, from whence they were brought into the European gardens. The ninth has been many years an inhabitant, where it has been usually titled *Corona Regalis*. This has a tuberoso root, from which arise in the autumn six or eight obtuse leaves, near five inches long and two broad toward the top, growing narrower at their base, and are crenated on their borders, lying flat on the ground; these continue all the winter: in the spring arises the flower-stalk in the center of the leaves, about six inches high, naked at the bottom; but the upper part is surrounded by bell-shaped flowers, composed of six greenish petals, with an oval germen situate at the bottom, surrounded by six stamina, supporting a triangular style, crowned by a trifid stigma; the germen afterwards becomes a roundish capsule, but rarely perfects seeds in England. This flowers in April, and the leaves decay in June.

The second sort I raised from seeds, which were sent me from the Cape of Good Hope: the root of this is like that of the ninth sort, but the leaves are more than a foot long, broad at their base, but are narrowed to the top, where they end in acute points; the flower-stalk rises rather higher than that of the ninth, but the flowers are of the same shape and colour: this seldom flowers till August. The roots of this sort were stolen out of the Chelsea garden the following spring after it had flowered, and were sold to some persons whose love for rare plants exceeded their honesty.

FRITILLARIA CRASSA. See *ASCLEPIAS*.

FRONDOSE [*frondosus*, *Lat.*] full of leaves, or shoots.

FROST may be defined to be an excessive cold state of the weather; whereby the motion and fluidity of the liquors are suspended; or, it is that state of the air, &c. whereby fluids are converted into ice.

By frost metals contract, or are shortened. *Monf. Auzout* found by an experiment, that an iron tube twelve feet long, upon being exposed to the air in a frosty night, lost two lines of its length; but this may be supposed to be wholly the effect of cold.

On the contrary, frost does not contract fluids, but, on the other hand, swells or dilates them near one tenth of their bulk.

Mr. Boyle gives us several experiments of vessels made of metals exceeding thick and strong, which being

filled with water, close stopped, and exposed to the cold, the water, being expanded by freezing, and not finding either room or vent, burst the vessels.

A strong barrel of a gun, with water in it, being stopped close, and frozen, was rent the whole length; and a small brass vessel, five inches deep, and two in diameter, filled with water, &c. and frozen, lifted up its lid, which was pressed with a weight of fifty-six pounds.

There are also related many remarkable effects of frost on vegetables. *Morery*, *Hist. de France*, says, That trees are frequently scorched and burnt up with frost, as with the most excessive heat, and that even in so warm a climate as *Provence*.

Mr. Bobart relates, That in the great frost anno 1683, Oaks, Ashes, Walnut-trees, &c. were miserably split and cleft, so as they might be seen through; and this too with terrible noises like the explosion of fire arms; that the cliffs were not only in the bodies, but continued to the larger boughs, roots, &c. *Philos. Transact.* N° 105.

Dr. Derham says, That the frost in 1708, was remarkable through the greatest part of Europe; and the greatest in degree, if not the most universal, in the memory of man; that it extended throughout England, France, Germany, Denmark, Italy, &c. but was scarce felt in Scotland and Ireland. All the Orange-trees and Olives in Italy, *Provence*, &c. and all the Walnut-trees throughout France, with an infinity of other trees, perished by the frost.

Mons. Gouteron says, They had a gangrene on them, which he takes to be the effect of a corrosive salt, which corrupted and destroyed their texture. He adds, That there is so much resemblance between the gangrene befalling plants through frost, and that which the parts of animals are liable to, that they must have some analogous cause. Corrosive humours burn the parts of animals, and the aerial nitre, condensed, has the same effects on the parts of plants. *Memoires de l'Academie Royale de Sciences*, an. 1709.

Dr. Derham says, That the greatest sufferers in the animal kingdom were birds and insects, but vegetables were much the greatest sufferers; that few of the tender sorts of vegetables escaped the severity of the frost; Bays, Laurels, Rosemary, Cypress, *Alaternuses*, *Phillyreas*, *Arbutuses*, *Laurustinuses*, and even *Furz*, with most sort of the frutescent herbs, as *Lavenders*, *Abrotanums*, *Rue*, *Thyme*, &c. were generally destroyed. He adds, that the sap of the finer wall-fruit was so congealed and destroyed, that it stagnated in the limbs and branches, and produced disorders like to chilblains in human bodies, which would turn to mortifications in many parts of the trees; that the very buds of the finer trees, both in the leaf, buds, and blossom buds, were quite killed, and dried into a farinacious matter.

Dr. Derham relates it as a common observation, That vegetables suffered more from the sun than from the frost, in that the sun-shine, melting the snow, and opening the ground, left it more exposed to the rigour of the ensuing night. It was likewise observed, at a meeting of the Royal Society, That the calamities which beset trees, arose not purely from their being frozen, but principally from the winds shaking and rocking them when they are frozen, which rent and parted their fibres. *Philos. Transact.* N° 324.

Hoar frost, or white frost, is the dew frozen, or congealed early in cold mornings, chiefly in autumn. This (as *Mr. Regis* observes) is an assemblage of little parcels of ice or crystals, which are of various figures, according to the disposition of the vapours which meet and are condensed by cold.

Dew is, to all appearance, the matter of hoar frost; though many of the *Cartesians* suppose it to be formed of a cloud, and either congealed in the cloud, and so let fall, or ready to be congealed as soon as it arrives at the earth.

In the year 1728-9, there was a remarkable frost, which continued for some months, and destroyed a great number of trees and plants in several parts of Europe, a brief

F R O

a brief account of which may not be improper to be here inserted.

The autumn began with cold north and east winds, and early in November the nights were generally frosty, though the frost did not enter the ground deeper than the sun thawed the following day; but toward the end of November the winds blew extremely cold from the north, which was succeeded by a great snow, which fell in such quantities in one night, as to break off large arms, as also the tops of many Evergreen-trees, on which it lodged. After the snow had fallen, it began to freeze again, the wind continuing to blow from the north; the days were dark and cloudy for some time, but afterwards it cleared up, and the sun appeared almost every day, which melted the snow where exposed to it, whereby the frost penetrated deeper into the ground. It was observable, that, during these clear days, a great mist or vapour, appeared in the evenings, floating near the surface of the ground until the cold of the night came on, when it was suddenly condensed, and disappeared. About the 8th of December, the nights were extremely cold; the spirits in the thermometer fell 18 degrees below the freezing point, and on the 10th of the same month the frost was as severe as had been known in the memory of man; the spirits of the thermometer fell to 20 degrees below the freezing point. At this time vast numbers of Laurustinuses, Phillyreas, Alaternuses, Rosemary, Arbutus, and other Evergreen-trees and shrubs began to suffer; especially such as had been trimmed up to heads with naked stems, or had been clipped late in autumn. At this time also there were great numbers of large deciduous trees disbarbed by the frost, as Pear-trees, Plane-trees, Walnut-trees, with many other sorts, and it was chiefly on the west and south-west side of the trees, that the bark came off.

About the middle of December the frost abated of its intenseness, and seemed to be at a stand till the 23d of the same month, when the wind blew extremely sharp and cold from the east, and the frost increased again, continuing very sharp till the 28th day, when it began to abate again, and seemed to be going off, the wind changing to the south; but it did not continue long in this point, before it changed to the east again, and the frost returned, though it was not so violent as before.

Thus the weather continued for the most part frosty, till the middle of March, with a few intervals of mild weather, which brought forward some of the early flowers; but the cold returning, soon destroyed them: so that those plants which usually flower in January and February, did not this year appear till March, and before they were fully blown, were cut off by the frost; of this number were all the Spring Crocuses, Hepaticas, Persian Irises, Black Hellebores, Meze-reons, with some others.

The Cauliflower plants, which were planted out of the beds in the open ground, during the intervals between the frost, were most of them destroyed, or so much cut, that they lost most of their leaves; the early Beans and Peas were most of them killed, and many fruit and forest trees, which had been lately removed, were quite destroyed. The loss was very great to some curious persons, who had been many years endeavouring to naturalize great numbers of exotic trees and shrubs, abundance of which were either totally killed, or destroyed to the surface of the ground; amongst this number there were many sorts destroyed, which had endured the open air many years, without receiving the least injury from the cold, such as Passion Flowers, Cork-trees, Cistuses, Rosemary, Stoechas; Sage, Mastich, and some others. In some places the young Ash and Walnut-trees were killed; but when the frost went off, there appeared to have been much more damage done in the gardens, than there really was, which occasioned many people to dig up and destroy large quantities of trees and shrubs, which they supposed were killed; whereas those who had more patience, and suffered them to remain, fared better;

F R O

for great numbers of them shot out again, some from their stems and branches, and others from their roots, the following summer.

Nor was the frost more severe in England; than in other parts of Europe; but, on the contrary, in comparison, favourable; for in the southern parts of France, the Olives, Myrtles, Cistuses, Alaternuses; and several other trees and shrubs, which grow there almost spontaneously, were either destroyed, or at least were killed to their roots; and about Paris, and the northern parts of France, the buds of their fruit-trees were destroyed, although they remained closed; so that there were very few blossoms which opened that spring. The Fig-trees were in several parts of France quite killed; and in England their tender branches were destroyed, so that there was very little fruit on those trees the following summer, except where they were protected from the frost.

In Holland the Pines and Firs, with several other trees, which are natives of cold countries, were greatly injured by the cold; and most of the trees and shrubs, which were brought from Italy, Spain, or the south parts of France, which had been planted in the full ground, in that country, were entirely killed, though many other sorts, which had been brought from Virginia and Carolina, escaped very well in the same gardens; but the person who suffered most in that country, was the learned Dr. Boerhaave, who had been several years endeavouring to naturalize as many exotic trees and shrubs as he could possibly obtain from the several parts of the world, great numbers of which were entirely destroyed by the frost this winter.

In some parts of Scotland they not only lost many of their curious flowers, plants, and trees; but great numbers of sheep, and other cattle, were buried under the snow, where they perished; and many poor people, who went to look after their cattle, were equal sufferers with them, being buried in the snow, which in some places fell eight or nine feet deep in one night.

It has been observed by thermometers, when that kind of hovering lambent fog arises (either mornings or evenings) which frequently betokens fair weather; that the air, which in the preceding day was much warmer, has, upon the absence of the sun become many degrees cooler than the surface of the earth, which being near 1500 times denser than the air, cannot be so soon affected with the alteration of heat and cold; whence it is probable, that those vapours which are raised by the warmth of the earth, are by the cooler air soon condensed into a visible form. The same difference has been observed between the coolness of the air, and the warmth of water in a pond, by putting a thermometer, which hung all night in the open air in summer time, into the water, just before the rising of the sun, when the like reek, or fog, was rising on the surface of the water.

In the year 1739-40, we had another severe winter, which did great mischief to the gardens, fields, and woods, the effects of which are yet, and will be many years, felt in Europe. Some particulars of these depredations, may not, perhaps, be unacceptable to the reader, if they are here mentioned.

The wind set in blowing from the north and north-east, about the autumnal equinox, and continued to blow from the same quarter, with little variation, upward of six months. Early in November, there was a continued sharp frost for nine days, in which time the ice upon large ponds, and other standing waters, was frozen so hard as to bear persons who skated thereon; but toward the end of November the frost abated, and there was little more than slight morning frosts until Christmas day, when it froze pretty hard that morning, and continued every morning so to do; but on the 28th day of December, the wind blew with great strength from the north-east, and brought on severe cold; that night the frost penetrated very deep into the ground, and the next day, viz. the 29th, the wind changed to the southward of the east, and blew with great fury; the thermometer fell this day to twenty:

twenty-five degrees below frost; in the morning some little snow fell, but the violence of the wind carried it off; but cold still increasing, the waters were all frozen over, and that day it was so intense, as to freeze the water of the river, which was raised by the force of the wind into ice, before it fell down again. The wind continued to blow with the same force, and from the same quarter, all the 30th day, the cold still increasing, so that at this time the frost penetrated into most of the green-houses in England, but especially into all those whose fronts had the least inclination to the east; and such of them as fronted the south-west escaped best; where the back walls were of a sufficient thickness to keep out the frost; the spirits in the thermometer fell in the night of the 30th day to thirty-two degrees below the freezing point, which was lower than it had been known in England before; the violence of the wind made it very troublesome for persons of the most robust constitutions to be abroad, and this also caused the frost to penetrate through thick walls, and in the space of two days, the Evergreen-trees and shrubs appeared as if they had been scorched by fire, so that they seemed to have no life; the only trees of all the sorts of Evergreens which retained their verdure at this time, were the Portugal Laurel, Savin, and shrubby Hartwood; these in the midst of this severe frost remained unhurt, when all the others were as brown as if they had been dead a year; and it was very late in the spring, before any of them resumed their usual verdure: during these severe days there had but little snow fallen, so that the frost penetrated deep in the ground, and destroyed the roots of great part of the vegetables, where they were not well secured; the Artichoke roots were most of them killed in all the kitchen-gardens, some few only escaped, these were such as were not intended to be preserved. A single row of these roots, which were growing in a place where a great quantity of dung had been wheeled over them, whereby the ground was rendered as hard as that of a common foot-way, though there was no covering upon these roots, yet they survived the frost and did well; another parcel which was growing near a tan-yard, where, by accident, some tan had been thrown, were preserved, so that from some of these accidents we were so lucky as to retrieve the good kind of Artichoke, which the English gardens were so famous for being stocked with.

By the sharp piercing winds the Grass was almost totally burned up, so that there was not the least verdure to be seen in the fields, and in many places the sweetest and best kinds of the herbage were entirely killed, so that there remained only the strong rough kinds of grass, whereby the pastures were in general much damaged; but on the 31st day in the evening, the wind being much abated, the severity of the frost was not so great, and there seemed an appearance of a thaw on the first and second of January, but on the third in the evening the frost set in again with great violence; and on the fourth of January in the morning, the thermometer was fallen one degree lower than it had been before. The same morning there was the greatest hoary frost which had been seen, the woods, trees, and hedges, appeared as if they had been covered with snow; and although there was no wind stirring, yet the air was so sharp and penetrating, as to render it difficult to endure the cold, even with great exercise.

The timber-trees suffered greatly that morning, especially the Oaks, which were split with great violence; and the noise in the woods that morning, resembled that of great branches breaking down in every part of the woods, and when heard at a distance, like the firing of guns. This was little attended to at the time, but the timber which has been since fallen, sufficiently proves the great damage which the woods then sustained; nor was it here the calamity stopped, for the Oaks in general had received so much injury from the frost, as to occasion such a weakness and distemper among them, that the

following spring they were infested with insects to such a degree, as that their leaves were eaten and entirely destroyed by them; so that at Midsummer the trees were as naked as if it had been the beginning of April; and this distemper continued for two years after, almost as bad as at first; and has lessened by degrees, as the trees have recovered their strength; and where the trees were old and weak, they have not yet gotten the better of this distemper.

The herbage was also so much weakened by the severity of the frost, as not to be able to resist the attack made upon it by insects, so that innumerable quantities of them were discovered in the pastures in many parts of Europe, beginning first in the northern countries, and afterward spreading to the south; and these insects in many places were so numerous, as to destroy the sward of Grass, and it is to be feared the distemper which so long raged among the cattle may have been owing to this cause; for wherever the distemper spread, it has been observed, that numbers of these insects have harboured about the roots of the Grass: and as a farther proof of this, it has constantly been remarked, that, when these grubs are changed into a sort of beetle, and take their flight (which is commonly about the beginning of May,) the distemper ceases; and when these beetles have deposited their eggs in autumn, the distemper has raged again. Another remark has been made, that these beetles always chuse to deposit their eggs not at a great distance from rivers, or large pieces of water, and in such places the cattle have been most attacked. There might be many other circumstances mentioned in favour of this opinion, as also the several experiments which have been made by some of the members of the Academy of Sciences at Paris, which are sufficient to prove, that the distemper was not infectious, nor can be communicated by the cattle, notwithstanding it has been treated as such in many countries, where has been an immense loss to the public of such numbers of cattle and their hides; but this may require a particular treatise, therefore I shall not enlarge farther on this head at present.

The frost still continued very hard till toward the end of January, but not so violent as at the beginning; for had the wind continued to blow with so much force as it had done the three first days of the frost, for any considerable time longer, there would have been few vegetables able to have resisted the cold, nor would the animal kingdom have fared much better; for the cold was so intense during those few days, as to kill several of the weaker sort of cattle, where they were much exposed to the wind.

The Walnut-trees, Ash, and several other trees, had most of their shoots of the former year destroyed, which caused them to be very late before they put out their new shoots the following spring, and these shoots were produced from the two and three years branches. The Fig-trees in many places were killed almost to the ground, especially those which were growing against the best aspected walls, for those on the north and north-west aspects, as also the old standard Fig-trees escaped better; but all those stools and layers of these trees, which were growing in the nursery-gardens, were so much injured by the frost, as not to be recovered under three years, during which time there were scarce any of these plants to be sold. The layers of Vines, as also of the Oriental Plane-tree, in the nurseries, were likewise killed to the ground, and the old stools so much injured, that they had better have been dug up and thrown away, than to have continued them; for in ten years after they did not recover their former vigour, making their shoots so late in the summer, that their wood had not time to harden, and the first frost in autumn frequently killed them half way to the ground.

Many other deciduous trees were equal sufferers by this severe frost, and the Evergreens were more generally injured, and abundance of them killed. The Pine and Pinaster were so much hurt, as to lose all their verdure, and in some places the young plants of the

the former sort were entirely killed. The Rosemary, Lavender, Stoechas, Sage, and many other aromatic plants, were in many places quite destroyed, so that it was two or three years before the markets could be supplied with these; and in general the esculent plants in the kitchen-gardens were killed, so that for some months the markets were not supplied with any quantity of garden stuff. The flower-gardens also were great sufferers by this winter; for as the seasons for some years before had been very temperate, few persons had made any provision for a hard winter; and the cold setting in so very intense at the beginning, the mischief was done before people could be provided with covering.

The Wheat in many parts of England, but especially in the open common fields, was very much hurt, particularly on the top of the ridges, where, in several places there were broad naked spaces on the middle of the ridges, which in the spring appeared like so many foot-paths. And as the spring following was very dry, and the wind continuing to blow from the north and east; these piercing winds entered the ground, which had been loosened by the frost, and dried up the tender roots of the Corn, to the great prejudice of it; but some of the more expert farmers, who rolled their Wheat after the frost was over, were well repaid by the great crops which their land produced them.

Were I to enter into all the particulars of the damages sustained by this severe frost in the gardens and fields, it would swell this work beyond the limits intended; so I hope, on the other hand, I shall not be condemned for having inserted thus much, since, by the mention of these things, persons may be instructed how to save many of their valuable plants in future winters, as also what sorts are more liable to danger from frosts than others.

FRUCTIFEROUS [*fructifer, Lat.*] fruit-bearing, fruitful.

FRUCTUS. See **FRUIT**.

FRUIT is the production of a tree or plant, for the propagation or multiplication of its kind; in which sense fruit includes all kinds of seeds, with their furniture, &c. botanists use it to signify properly, that part of a plant wherein the seed is contained, which the Latins call *Fructus*, and the Greeks *καρπός*.

The fruit of some plants are produced singly, as are their flowers, and sometimes they are produced in clusters, as in most fruit-trees, which are also fleshy, but in many plants they are dry.

The word fruit is also used to signify an assemblage of seeds in a plant; as in a Pea, Bean, Ranunculus, &c. and in its general signification, for all kinds of grain, whether naked, or inclosed in cover, capsula, or pod, whether bony, fleshy, skinny, membranous, or the like.

Fruit is the product or result of the flower, or that for whose production, nutrition, &c. the flower is intended.

The structure and parts of different fruits are different in some things, but in all the species the essential parts of the fruit appear to be only continuations or expansions of those which are seen in the other parts of the tree.

Dr. Beale suggests some very good reasons for a direct communication between the remotest parts of the tree and the fruit; so that the same fibres which constitute the root, trunk, and boughs, are extended into the very fruit.

Thus, if you cut open an Apple transversely, you will find it to consist chiefly of four parts, viz. 1st, a skin, or cortex, which is only a production of the skin or outer bark of the tree. 2dly, A parenchyma or pulp, which is an expansion and intumescence of the inner bark of the tree. 3dly, The fibres, or ramifications of the woody part of the tree. 4thly, The core, which is the produce of the pith, or medulla of the plant, indurated or strengthened by twigs of the wood and fibres insculated therewith. This serves to furnish a cell, or lodge, for the kernels, filtrates

the juice of the parenchyma, and conveys it thus prepared to the kernel.

Of the fibres, authors generally reckon fifteen branches, of which ten penetrate the parenchyma, and incline to the basis of the flower; the other five ascend more particularly from the pedicle or stalk, and meet with the former at the base of the flower, to which branches the capsulae, or coats of the kernels are fastened.

These branches being first extended through the parenchyma to the flower, furnish the necessary matter for the vegetation of it; but as the fruit increases, it intercepts the aliment, and thus the flower is starved, and falls off.

In a Pear there are five parts to be distinguished, viz. the skin, parenchyma, ramification, kernel, and acetarium.

The three first parts are common to the Apple. The kernel, observed chiefly in Choke Pears, or Breaking Pears, is a congeries of strong corpuscles, that are dispersed throughout the whole parenchyma, but in the greatest plenty, and closest together about the center, or acetarium; it is formed of the stony or calculous part of the nutritious juice.

The acetarium is a substance of a tart acid taste, of a globular figure, inclosed in an assemblage of several of the stony parts before-mentioned.

In a Plumb, Cherry, &c. there are four parts, viz. a coat, parenchyma, ramification, and nucleus, or stone. The stone consists of two very different parts; the external or harder part, called the stone, or shell, is a concretion of the stony, or calculous parts of the nutritious juice, like the kernel in Pears, within it. The inner, called the kernel, is soft, tender, and light, being derived from the pith, or medulla of the tree by seminal branches, which penetrate the base of the kernel.

The nut, or acorn, consists of a shell, cortex, and medulla; the shell consists of a coat and parenchyma, derived from the bark and wood of a tree.

The cortex consists of an inner and outer part, the first is a duplicature of the inner tunic of the shell; the second is a mossy substance, derived from the same source as the parenchyma of the shell. But authors are not agreed, whether the medulla, or pulp of the kernel does arise from the pith of the tree, or the cortical part thereof.

Berries, as the Grape, &c. contain (besides three general parts, viz. coat, parenchyma, and ramification) grains of a stony nature, to do the offices of seeds.

Fruits in general are serviceable in guarding, preserving, and feeding the inclosed seed, in filtrating the coarser more earthy, and strong parts of the nutritious juice of the plant, and retaining it to themselves, sending none but the most pure, elaborated, and spirituous parts to the seed, for the support and growth of the tender delicate embryo or plantule, which is therein contained.

FRUMENTACEOUS [*Frumentaceus, Lat.*] a term applied by botanists to all such plants as have a conformity with Wheat (called in *Latin* *Frumentum*), in respect either of their fruits, leaves, ears, or the like.

FRUMENTUM INDICUM. See **ZEA**.

FRUTEX, a shrub; a vegetable of a genus between a tree and an herb, but of a woody substance. It is pretty difficult to determine wherein most of the writers on gardening and agriculture have made the distinction between trees and shrubs, or where to fix the difference or boundary, between the trees and shrubs, to say where one ends, and the other begins, for that cannot be determined by their growth; therefore the best definition which can be made of a shrub, to distinguish it from a tree, is its sending forth many stems from the roots, whereas the trees have a single trunk or body.

FRUTEX PAVONIUS. See **POINCIANA**.

FRUTICOSE [*Fruticofus, Lat.* shrubby,] are those plants which are of a hard woody substance, and do not rise to the height of trees.

FUMARIA A. Plum. Nov. Gen. 14. Lin. Gen. Plant. 1097. This plant was so named by Father Plumier, who discovered it in America, in honour of the memory of Leonard Fuchsius, a learned botanist.

The CHARACTERS are,

The flower hath no empalement; it hath one petal, with a closed tube, which is slightly cut into eight parts at the brim, ending in acute points; it hath four stamina the length of the tube, which are terminated by obtuse summits. The oval germen is situated under the flower, supporting a single style, crowned by an obtuse stigma. The germen afterward becomes a succulent berry with four furrows, having four cells, containing several small oval seeds.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

We know but one SPECIES of this genus at present, viz.

FUCHSIA (*Triphylla*.) Lin. Sp. Plant. 1191. *Three-leaved Fuchsia*. *Fuchsia triphylla*, flore coccineo. Plum. Nov. Gen. *Three-leaved Fuchsia with a scarlet flower.*

This plant is a native in the warmest parts of America; it was discovered by Father Plumier, in some of the French Islands in America, and was since found by the late Dr. William Houstoun, at Carthage in New Spain, from whence he sent the seeds into England.

This is propagated by seeds, which must be sown in pots filled with rich light earth, and plunged into a hot-bed of tanners bark, and treated in the same way as other seeds from warm countries. In about a month or six weeks after the seeds are sown, the plants will begin to appear, when they should be carefully cleared from weeds, and frequently refreshed with water to promote their growth; and when they are about two inches high, they should be shaken out of the pot, and separated carefully; then plant each into a small pot filled with light rich earth, and plunge them again into a hot-bed of tanners bark, being careful to screen them from the sun until they have taken new root; after which time they must have fresh air admitted to them every day in proportion to the warmth of the season, and should be frequently watered. As the season advances and becomes warm, the glasses of the hot-bed should be raised higher, to admit a greater share of air to the plants, to prevent their drawing up weak; and when the plants are grown so tall as to reach the glasses, they should be removed into the bark-stove, and plunged into the tan-bed. In winter these plants require to be kept very warm, and at that season they must not have much water, but in summer it must be often repeated.

These plants are too tender to thrive in the open air in this country, even in the hottest part of the year; therefore they should constantly remain in the stove, observing to let in a large share of fresh air in summer, but in winter they must be kept warm; with this management the plants will produce their flowers, and make a beautiful appearance in the stove, amongst other tender exotic plants.

FUMARIA. Lin. Gen. Plant. 760. Tourn. Inst. R. II. 421. tab. 237. *Fumatory*; in French, *Fumeterre*.

The CHARACTERS are,

The empalement of the flower is composed of two equal leaves placed opposite. The flower is of the ringent kind, approaching near to the butterfly flowers. The upper lip is plain, obtuse, indented at the top, and reflexed; the nectarium at the base of this is obtuse, and a little prominent. The under lip is like the upper in all its parts, but the base is keel-shaped; the nectarium at the base is less prominent. The chaps of the flower is four-cornered, obtuse, and perfectly bifid; there are six equal broad stamina in each flower, divided in two bodies, included in the two lips, each being terminated by three summits. In the center is situated an oblong germen, supporting a short style, crowned by an orbicular compressed stigma. The germen afterward becomes a short pod with one cell, including roundish seeds.

This genus of plants is ranged in the first section

of Linnæus's seventeenth class, intitled Diadelphia Hexandria, which includes the plants whose flowers have their stamina in two bodies, and have six stamina. To this genus Dr. Linnæus has joined the *Capnoides* of Tournefort, the *Cysticapnos* of Boerhaave, the *Corydalis* of Dillenius, and the *Cucularia* of Jussieu, making them only species of the same genus.

The SPECIES are,

1. *FUMARIA* (*Officinalis*) *pericarpis monospermis racemosis, caule diffuso*. Lin. Sp. Plant. 700. *Fumatory with seed-vessels growing in a racemus, with a single seed and a diffused stalk*. *Fumaria officinarum* & *Dioscoridis*, flore purpureo. C. B. 143. *The common Fumatory with a purple flower.*
2. *FUMARIA* (*Spicata*) *pericarpis monospermis spicatis, caule erecto, folioliis filiformibus*. Sauv. Monsp. 263. *Fumatory with seed-vessels growing in a spike, with one seed, an upright stalk, and thread-like leaves*. *Fumaria minor tenuifolia*. C. B. 143. *Lesser narrow-leaved Fumatory.*
3. *FUMARIA* (*Alba*) *filiquis linearibus tetragonis, caulibus diffusis acutangulis*. Lin. Sp. Plant. 700. *Fumatory with narrow four-cornered pods, and diffused stalks, having acute angles*. *Fumaria sempervirens* & *floreas*, flore albo. Flor. Bat. *Evergreen Fumatory with a white flower.*
4. *FUMARIA* (*Capnoides*) *filiquis teretibus, caulibus diffusis, angulis obtusis*. *Fumatory with taper pods and diffused stalks, having obtuse angles*. *Fumaria lutea*. C. B. 143. *Yellow Fumatory.*
5. *FUMARIA* (*Claviculata*) *filiquis linearibus, foliis cirrhiferis*. Lin. Sp. Plant. 701. *Fumatory with narrow pods, and leaves having clasps*. *Fumaria claviculis donata*. C. B. P. 143. *Fumatory with tendrils.*
6. *FUMARIA* (*Capreolata*) *pericarpis monospermis racemosis, foliis scandentibus subcirrhosis*. Lin. Sp. Plant. 701. *Fumatory with seed-vessels growing in a racemus, with one seed, and climbing leaves having short tendrils*. *Fumaria major scandens*, flore pallidior. Raii Hist. 405. *Greater climbing Fumatory with a paler flower.*
7. *FUMARIA* (*Cava*) *caule simplici, bracteis longitudine florum*. Lin. Sp. Plant. 699. *Fumatory with a single stalk, and bractee as long as the flowers*. *Fumaria bulbosa*, radice cavâ, major. C. B. P. 143. *Greater bulbous Fumatory with a hollow root.*
8. *FUMARIA* (*Bulbosa*) *caule simplici, bracteis brevioribus multifidis, radice solida*. *Fumatory with a single stalk, shorter many pointed bractee, and a solid root*. *Fumaria bulbosa*, radice non cavâ, major. C. B. P. 144. *Greater bulbous Fumatory with a solid root.*
9. *FUMARIA* (*Cucularia*) *scapo nudo*. Hort. Cliff. 351. *Fumatory with a naked stalk*. *Capnorchis Americana*. Boerh. Ind. alt. 1. 309. and the *Fumaria tuberosa* insipida. Cornut. 129. *Tuberous insipid Fumatory.*
10. *FUMARIA* (*Vesicaria*) *filiquis globosis inflatis*. Hort. Upsal. 207. *Fumatory with globular inflated pods*. *Cysticapnos Africana scandens*. Boerh. Ind. alt. 1. 310. *Climbing African Cysticapnos.*
11. *FUMARIA* (*Eneaphylla*) *foliis triternatis, foliolis cordatis*. Lin. Sp. Plant. 700. *Fumatory with leaves composed of three trifoliate small leaves, which are heart-shaped*. *Fumaria enneaphyllos Hispanica saxatilis*. Bocc. Mus. 2. p. 83. *Five-leaved Rock Fumatory of Spain.*
12. *FUMARIA* (*Sempervirens*) *filiquis linearibus paniculatis, caule erecto*. Hort. Upsal. 207. *Fumatory with narrow pods growing in panicles, and an upright stalk*. *Capnoides*. Tourn. Inst. R. H. 423. *Bastard Fumatory.*

The first sort is the common Fumatory which is used in medicine. This grows naturally on arable land in most parts of England; it is a low annual plant, and flowers in April, May, and June; and very often from plants which rise late in the summer, there will be a second crop in autumn. The juice of this plant is greatly commended for bilious cholics. It is never cultivated in gardens.

The second sort grows naturally in the south of France, Spain, and Portugal, but is preserved in botanic gardens for the sake of variety. It is an annual plant,

F U M

plant, which rises from the scattered seeds better than when it is sown with care; the stalks of this grow more erect, the leaves are very finely divided, and the flowers grow in a close spike; they are of a deep red colour, and flower about the same time as the common fort.

The third fort grows naturally on the borders of the Mediterranean Sea; it was first brought to England from Tangier. This is a perennial plant, which sends out from the root many branching stalks, which rise about six or eight inches high, growing in tufts or bunches; the leaves are very much divided, the stalks are angular, and the flowers grow in loose panicles upon naked foot-stalks, which come out from the divisions of the branches; they are of a whitish yellow colour, and there is a succession of them most part of the year.

The fourth fort hath an appearance very like the third, and by some it is supposed to be only a variety of that, but is undoubtedly a distinct species; for I have cultivated both more than forty years, and never yet found either of them to vary. The stalks of this fort have blunt angles, whereas those of the third are acute; they are of a purplish colour, and the flowers grow in looser panicles, each having a longer foot-stalk than those of the other; they are of a bright yellow colour, and there is a succession of them great part of the year.

These two forts continue green all the year, and except in very severe frost, are always in flower, which make a pretty appearance; they grow best on walls or rocks, and are very proper for the joints of grottos, or any rock-work; where, if a few plants are planted, or the seeds scattered, they will multiply fast enough from their scattering seeds, which are cast out of the pods by the elastic spring of the valves when ripe, to a considerable distance; and as the plants will require no care to cultivate them, they should not be wanting in gardens.

The fifth fort grows in stony and sandy places in some parts of England; it is an annual plant with trailing stalks, sending out clasps from the leaves, which fasten to any of the neighbouring plants. It flowers in May and June, but is never cultivated in gardens.

The sixth fort is an annual plant with many trailing stalks, which grow about a foot long, sending out a few short tendrils, whereby they fasten to any neighbouring support; the flowers come out from the side of the stalks in loose bunches; they are of a whitish herbaceous colour, with a purple spot on the upper lip. This flowers in May and June. It grows in France and Italy, on stony places in the shade.

The seventh fort grows naturally in the south of France and Italy, and was some years past preserved in the English gardens by way of ornament, but is now rarely to be found here; it was titled *Radix cava*, or hollow root, from its having a pretty large tuberous root hollowed in the middle. The stalk of this fort rises about six inches high, and does not divide, but is garnished toward the bottom with one ramous leaf, somewhat like the common Fumatory, but the lobes are broader; the flowers grow in a spike at the top of the stalk; they are of a pale herbaceous colour, and appear in April. This plant delights in the shade, and is multiplied by offsets, for it rarely ripens seeds in England.

The eighth fort is pretty common in many of the old gardens in England; it grows naturally in the south of France, in Germany and Italy. This hath a pretty large round solid root of a yellowish colour, from which come out branching leaves like those of the last fort, but the lobes are longer; the flowers grow in spikes on the top of the stalks; they are of a purple colour, and come out early in April. The stalks of this fort are single, and rise about four or five inches high.

There is a variety of this with green flowers, which is mentioned in most of the books; but all the plants of this fort which I have yet seen, are only abortive,

F U M

having no real flower, only a green bractea, which has been generally taken for the flowers: there is also mentioned a larger fort; but if there is one which is really different from the common fort, I have not seen it in the English gardens, nor the yellow and white flowering forts, which are also mentioned in many of the books.

The ninth fort grows naturally in North America; this hath a scaly root about the size of a large Hazel Nut, from which come out three or four leaves upon slender foot-stalks; these are divided into three parts, each of these parts is composed of many smaller divisions, which have narrow lobes, divided into three parts almost to the bottom; the flower-stalk is naked, and eight or nine inches long; this is terminated by four or five flowers, growing in a loose spike; these have two petals, which are reflexed backward, and form a sort of fork toward the foot-stalk, and at their base are two horned nectariums, which stand horizontal. The flowers are of a dirty white colour and appear in May, but rarely produce seeds here.

This is propagated by offsets from the root; it loves a shady situation and a light soil; the best time to transplant the roots is in autumn, when the leaves are decayed, for it shoots pretty early in the spring, therefore it would not be safe to remove them at that season.

The tenth fort grows naturally at the Cape of Good Hope; this is an annual plant, with trailing stalks which are two or three feet long, dividing into many smaller, which are garnished with small branching leaves shaped like those of the common Fumatory, but end with tendrils, which clasp to any neighbouring plants, and thereby the stalks are supported; the flowers are produced in loose panicles, which proceed from the side of the stalks; they are of a whitish yellow colour, and are succeeded by globular swollen pods, in which are contained a row of small shining seeds.

This is propagated by seeds, which should be sown upon a moderate hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a small pot filled with light earth, and plunged again into the hot-bed, where they must be shaded from the sun till they have taken new root; after which they should have a large share of air admitted to them at all times in mild weather, to prevent their drawing up weak; and as soon as the season is favourable, they should be inured to bear the open air, to which they may be removed the beginning of June, when they may be shaken out of the pots, preserving all the earth to their roots, and planted in a warm border, where their stalks should be supported with sticks to prevent their trailing on the ground; and in July the plants will flower, and continue a succession of flowers till the frost destroys the plants; the seeds ripen in autumn.

The eleventh fort grows naturally upon old walls, or rocky places in Spain and Italy; this hath weak trailing stalks which are much divided, and are garnished with small leaves divided into three parts, each of which hath three heart-shaped lobes; the flowers are produced in small loose panicles from the side of the stalks, they are of a greenish white, and appear most of the summer months. It is an abiding plant, which propagates itself by the seeds that scatter, and thrives best in a shady situation, and on old walls or buildings.

The twelfth fort is an annual plant with an upright stalk, which grows a foot and a half high, round and very smooth, sending out several branches upward; these are garnished with smooth branching leaves, of a pale colour, which are divided like the common fort, but the small leaves are larger and more obtuse; the flowers are produced in loose panicles from the sides of the stalks, and at the extremity of the branches; they are of a pale purple colour, with yellow chaps (or lips); these are succeeded by taper narrow pods an inch and a half long, which contain many small shining black seeds. This flowers during most of the summer months, and the seeds ripen in July, August,

F U M

gust, and September. If the seeds of this plant are permitted to scatter, the plants will come up without any trouble, and require no other care but to thin them where they are too close, and keep them clean from weeds.

These plants may be suffered to grow on walls, and in some abject part of the garden; for if they are admitted into the borders of the pleasure-garden, they will scatter their seeds, and become troublesome weeds; but they are very proper plants to grow on ruins, or on the sides of grottos or rock-work, where, by their long continuance in flower, they will have a good effect.

The fifth, sixth, seventh, and eighth sorts are propa-

F U R

gated by offsets, as other bulbous-rooted flowers; these produce their flowers in the beginning of April, and are very pretty ornaments to borders in a small flower-garden. They are extreme hardy, but do not increase very fast, seldom producing seeds with us; and their bulbs do not multiply very much, especially if they are often transplanted. They love a light sandy soil, and should be suffered to remain three years undisturbed, in which time they will produce several offsets. The best season for transplanting them is from May to August, when the leaves begin to die off; for if they are taken up when their leaves are fresh, it will greatly weaken their roots.

F U R Z. See GENISTA.

G.

G A L

GALANTHUS. Lin. Gen. Plant. 362. Narcisso-leucoium. Tourn. Inst. R. H. 387. tab. 208. The Snow-drop; in French, *Perce-neige*.

The CHARACTERS are,

The spathe or sheath of the flower is oblong, blunt, and compressed. This opens sideways, and becomes a dry skin; the flower has three oblong concave petals, which spread open, and are equal; in the bottom is situated the three-leaved nectarium, which is cylindrical, obtuse, and indented at the top; under the flower is situated the oval germen, supporting a slender style, which is longer than the stamina, crowned by single stigma; this is attended by six short hairy stamina, terminated by oblong pointed summits, which are gathered together. The germen afterward becomes an oval capsule which is obtuse and three-cornered, opening in three cells, which are filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, which includes the plants whose flowers have six stamina and one style.

This plant, as also the great Snow-drop, was by Dr. Tournefort ranged together under the title of Narcisso-leucoium; which being a compound name, Dr. Linnæus has altered it to this of Galanthus; and has separated the great Snow-drop from this, and given the simple name of Leucoium to that genus.

We know but one SPECIES of this genus, viz.

GALANTHUS (*Nivalis*.) Lin. Hort. Cliff. 134. The common Snow-drop. *Leucoium bulbosum trifolium minus*. C. B. P. The least bulbous Snow-drop with three leaves.

There is a variety of this with double flowers.

These flowers are valued for their early appearance in the spring, for they usually flower in February when the ground is often covered with snow. The single sort comes out the first, and though the flowers are but small, yet when they are in bunches, they make a very pretty appearance; therefore these roots should not be planted single, as is sometimes practised by way of edging to borders; for when they are so disposed, they make very little appearance. But when there are twenty or more roots growing in a close bunch, the flowers have a very good effect; and as these flowers thrive well under trees or hedges, they are very proper to plant on the sides of the wood-walks, and in wilderness-quarters; where, if they are

G A L

suffered to remain undisturbed, the roots will multiply exceedingly. The roots may be taken up the latter end of June, when their leaves decay, and may be kept out of the ground till the end of August, but they must not be removed oftener than every third year.

G A L E. See MYRICA.

G A L E G A. Lin. Gen. Plant. 770. Tourn. Inst. R. H. 398. tab. 222. Goat's-rue.

The CHARACTERS are,

The empalement of the flower is short, tubulous, and of one leaf, indented in five parts. The flower is of the butterfly kind; the standard is oval, large, and reflexed; the wings are near the length of the standard; the keel is erect, oblong, and compressed; the under side toward the point is rounded, but the upper is acute; there are ten stamina, which join above their middle, and are terminated by small summits. In the center is situated a narrow, cylindrical, oblong germen, supporting a slender style, crowned by a stigma terminated by a puncture. The germen afterward becomes a long pointed pod, inclosing several oblong kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, which includes those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. GALEGA (*Officinalis*) leguminibus strictis erectis, foliis lanceolatis strictis nudis. Lin. Sp. Plant. 1062. Goat's-rue with erect close pods, and spear-shaped naked leaves. Galega vulgaris, floribus cæruleis. C. B. P. 352. Common Goat's-rue with blue flowers.
2. GALEGA (*Africana*) foliolis lanceolatis obtusis, floribus spicatis longioribus, siliquis crassioribus. Goat's-rue with obtuse spear-shaped leaves, flowers growing in longer spikes, and thicker pods. Galega Africana, floribus majoribus siliquis crassioribus. Tourn. Inst. R. H. 399. African Goat's-rue, with larger flowers and thicker pods.
3. GALEGA (*Frutescens*) foliis ovatis, floribus paniculatis alaribus, caule fruticoso. Goat's-rue with oval leaves, and flowers growing in panicles from the sides of the stalks, which are shrubby. Galega Americana, foliis subrotundis, floribus coccineis. Houst. MSS. American Goat's-rue with roundish leaves and scarlet flowers.
4. GALEGA (*Virginiana*) leguminibus retrofalcatis compressis villosis spicatis, calycibus lanatis, foliolis ovali-oblongis acuminatis. Amœn. Acad. 3. p. 18. Goat's-rue with hairy, compressed, sickle-shaped pods, oblong oval-

oval-pointed leaves, and woolly empalements. *Orobis Virginianus*, foliis fulva lanugine incanis, foliorum nervo in spinam aberunte. Pluk. Mant. 142.

5. *GALEGA (Purpurea)* leguminibus strictis adscendentibus glabris racemosis terminalibus, stipulis subulatis, foliis oblongis glabris. Flor. Zeyl. 301. *Goats-rue* with close, smooth, ascending pods, terminating the stalks in an oblong bunch, awl-shaped stipule, and oblong smooth leaves. *Coronilla Zelanica* herbacea, flore purpurascens. Burm. Zeyl. 77.

The first sort grows naturally in Italy and Spain, but is propagated in the English gardens for medicinal use. This hath a perennial root, composed of many strong fibres, which are frequently jointed, from which arise many channelled hollow stalks, from two to three feet high, which are garnished with winged leaves, composed of six or seven pair of narrow spear-shaped lobes, terminated by an odd one, which are smooth and entire; the flowers terminate the stalks growing in spikes, they are of the Pea-blossom shape, and of a pale blue colour, and are disposed in loose spikes. They appear in June, and are succeeded by taper pods about one inch and a half in length, having one row of kidney-shaped seeds, which ripen toward the end of August.

There is a variety of this with white flowers, and another with variegated flowers, which have accidentally been produced from seeds, so are not constant, therefore are only mentioned here.

The second sort grows naturally in Africa; this differs from the former, in having larger leaves, which are composed of eight or ten pair of lobes, broader and blunter at their ends than those of the common sort; the flowers are larger, and the spikes are longer; the seed-pods are also much thicker than those of the common sort, but in other respects are very like it.

These plants are propagated by seeds, which may be sown either in the spring or autumn, upon a bed of ground in an open situation; and when the plants come up, they must be kept clean from weeds till they are strong enough to remove; then a spot of ground should be prepared, in size proportionable to the quantity of plants designed; this should be well dug, and cleared from the roots of all noxious weeds; then the plants should be carefully taken up, and planted in rows at a foot and a half distance, and in the rows one foot asunder, observing to water them till they have taken new root; after which they will require no farther care to keep them clean from weeds, which may be easily done by hoeing of the ground frequently between the plants, and in the spring the ground between the rows should be dug, which will encourage their roots, and cause them to shoot out vigorous stalks; and if their stalks are cut down before the seeds are formed every year, the roots will continue the longer, especially if they grow on a light dry soil. The seeds of these will grow wherever they are permitted to scatter, so that plenty of the plants will come up without any care, and these may be transplanted and managed in the same manner as is before directed.

The first sort is used in medicine; it is accounted cordial, sudorific, and alexipharmic, so very good against pestilential distempers, expelling the venom through the pores of the skin, and is of use in all kinds of fevers. Mr. Boyle, in his treatise of the Wholsomeness and Unwholsomeness of the Air, bestows three or four pages, in celebrating the virtues of *Goats-rue* in pestilential and malignant diseases, from his own observation and experience.

The third sort was discovered by the late curious botanist Dr. William Houstoun, at Campeachy, from whence he sent the seeds into Europe. This plant is propagated by seeds, which must be sown on a hot-bed early in the spring; and when the plants come up, and are fit to transplant, they must be transplanted each into a separate small pot, and plunged into a hot-bed of tanners bark, shading them from the sun till they have taken new root; then they must be treated as hath been directed for other

tender plants, which are kept in the bark-stove. With this management they will flower in July, and in September they will perfect their seeds, but the plants may be preserved through the winter in the bark-stove.

The fourth sort grows naturally in Virginia and Carolina; this hath a perennial root, and an annual stalk which rises three feet high; the lobes of the leaves are oblong and oval, generally seven or nine to each leaf: the whole plant is covered with a silvery down. The flowers are of a red colour, and are produced in spikes at the end of the branches: these are succeeded by sickle-shaped compressed pods of a silvery colour, containing one row of kidney-shaped seeds.

This plant, although it is tolerable hardy, yet it is with difficulty preserved in gardens; for the seeds rarely ripen in England, and the plants are often destroyed by frost in winter. The only method in which I have been able to keep the plant, has been by potting them, and placing them in a common frame in winter, where they enjoyed the free air in mild weather, but were protected from frost; in this way I have kept the plant three years, but it has not ripened seeds here.

The fifth sort grows naturally in Ceylon, and in many parts of India, from whence I have received the seeds. This sort was annual here, and decayed before the seeds were ripe. It hath an herbaceous stalk; which rises two feet high, garnished with winged leaves, composed of eight or nine pair of oval lobes, terminated by an odd one; the foot-stalks of the flowers come out opposite to the leaves; these sustain a long loose spike or thyrse of small purple flowers, which are succeeded by slender erect pods.

This may be cultivated in the same way as the third sort; and if the plants are brought forward early in the spring, if the summer proves warm, the seeds may ripen.

GALENIA: Lin. Gen. Plant. 443. *Sherardia*. Ponted. Epist. 14.

The title of this genus was given to it by Dr. Linnaeus, from the famous physician Galen.

The CHARACTERS are;

The flower hath a small quadrifid empalement of one leaf; it hath no petals, but hath eight hairy stamina the length of the empalement, terminated by double summits. In the center is situated a roundish germen, supporting two reflexed styles, crowned by simple stigmas. The empalement afterward becomes a roundish capsule with two cells, containing two oblong angular seeds.

This genus of plants is ranged in the second section of Linnaeus's eighth class, intitled *Octandria Digynia*, which includes those plants whose flowers have eight stamina and two styles:

We know but one SPECIES of this genus; viz.

GALENIA (Africana): HORT. Cliff. 150. *Shrubby Galenia*. *Sherardia*. Ponted. Epist. 14. and the *Atriplex Africana*, lignosa frutescens, rosinarini foliis. Hort. Pis. 20. *Shrubby African woody Atriplex*, with *Rosemary* leaves.

This shrub grows naturally at the Cape of Good Hope, and in other parts of Africa; it rises with a shrubby stalk about four or five feet high, sending out many weak branches, garnished with very narrow leaves, which are placed irregularly on every side the branches; they are of a light green, with a furrow running longitudinally through the middle; the flowers are produced in loose panicles from the side and at the end of the branches; they are very small, and have no petals, so make little appearance. The flowers come out in July and August, but are not succeeded by seeds in England.

This plant will not live through the winter in the open air in England, so must be placed in the greenhouse, or under a frame, with other hardy exotic plants, where it may have a large share of air in mild weather, for it only requires to be protected from frost. In the summer it may be exposed in the open air, with other plants of the same country, and in dry weather it must be frequently watered. This may be

propagated by cuttings, which, if planted during any of the summer months, and watered frequently, will take root in about five or six weeks, and may then be treated as is directed for the old plants.

GALEOPSIS. Lin. Gen. Plant. 637. Tourn. Inst. R. H. 185. tab. 86. Stinking Dead Nettle.

The CHARACTERS are,

The empalement of the flower is tubulous, of one leaf, cut into five segments, which end in acute points. The flower is of the lip kind, having a short tube; the chaps are a little broader, but the length of the empalement; from the base to the under lip, it is on both sides sharply indented; the upper lip is concave, roundish, and sawed at the top; the under lip is trifid, the middle segment being the largest, which is crenated. It hath four stamina inclosed in the upper lip, two being shorter than the other, terminated by roundish bifid summits. In the center is situated a quadrifid germen, supporting a slender style, crowned by a bifid acute stigma. The germen afterward become four naked seeds, sitting in the rigid empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, intitled Didynamia Gymnospermia, which includes those plants whose flowers have two long and two short stamina, and the seeds are naked.

The SPECIES are,

1. **GALEOPSIS (Ladanum)** internodiis caulinis æqualibus, verticillis omnibus remotis. Lin. Sp. Plant. 579. *Stinking Hedge Nettle, with equal distances between the joints, and whorls growing at a distance. Sideritis arvensis angustifolia rubra. C. B. P. 233. Red narrow-leaved Field Ironwort.*
2. **GALEOPSIS (Tetralix)** internodiis supernè incrassatis, verticillis summis subcontiguis. Lin. Sp. Plant. 579. *Stinking Hedge Nettle, whose joints are thicker above, and the whorls at the top growing near each other. Lamium cannabinum folio vulgare. Raii Syn. Ed. 3. p. 240. Common Dead Nettle with a Hemp leaf.*
3. **GALEOPSIS (Speciosa)** corollâ flavâ, labio inferiore maculato. Flor Lapp. 193. *Stinking Hedge Nettle with a yellow flower, whose under lip is spotted. Lamium cannabinum aculeatum flore luteo specioso, labiis purpureis. Pluk. Alm. 204. Prickly Hemp Dead Nettle, with a beautiful yellow flower and purple lips.*
4. **GALEOPSIS (Galeobdolon)** verticillis sexfloris, involucro tetraphyllo. Lin. Sp. Plant. 780. *Stinking Hedge Nettle with six flowers in each whorl, and a four-leaved involucre. Galeopsis five urtica iners flore luteo. J. B. 3. 323. Stinking or Dead Nettle with a yellow flower.*
5. **GALEOPSIS (Orientale)** verticillis bifloris, foliis oblongo-cordatis. *Stinking Hedge Nettle with two flowers in each whorl, and oblong heart-shaped leaves. Galeopsis Orientalis ocimastri folio, flore majore flavescente. H. R. Par. Eastern Stinking Hedge Nettle, with an Ocimastrum leaf, and a larger yellowish flower.*
6. **GALEOPSIS (Hispanica)** caule piloso, calycibus labio corollæ superiore longioribus. Lin. Sp. Plant. 580. *Stinking Hedge Nettle with a hairy stalk, and the empalement longer than the upper lip of the petal. Galeopsis annua Hispanica, rotundior folio. Inst. R. H. 186. Annual Spanish Stinking Hedge Nettle, with a rounder leaf.*

These are all of them annual plants, except the fourth sort; the three first grow naturally in England. The first is found upon arable land in many places; the second grows upon dunghills, and by the side of paths, in many parts of England. The third sort grows chiefly in the northern counties, but I have found it growing wild in Essex, within ten miles of London. These plants are seldom cultivated in gardens, for if their seeds are permitted to scatter, the plants will come up as weeds wherever they are allowed a place.

The fourth is a perennial plant with a creeping root; this grows in the woods and under hedges in most parts of England. The fifth grows in the Levant; this is a biennial plant, which perishes soon after the seeds are ripe. It is preserved in botanic gardens for the sake of variety, but hath no great beauty.

GALEOPSIS FRUTESCENS. See PRASIVM.

GALIUM. Lin. Gen. Plant. 117. Tourn. Inst. R. H. 114. tab. 39. Ladies Bedstraw, or Cheese-rennet; in French, *Caillelait*.

The CHARACTERS are,

The flower hath a small empalement indented in four parts, sitting upon the germen. It hath one petal, divided into four segments almost to the bottom; and four axel-shaped stamina which are shorter than the petal, terminated by single summits. It hath a twin germen situated under the flower, supporting a slender half bifid style, crowned by a globular stigma. The germen afterward become two dry berries, which are joined together, each inclosing a large kidney-shaped seed.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, which includes those plants whose flowers have four stamina and one style:

The SPECIES are,

1. **GALIUM (Verum)** foliis octonis linearibus fulcatis, ramis floriferis brevibus. Hort. Cliff. 34. *Ladies Bedstraw with eight narrow furrowed leaves, and short flowering branches. Galium luteum. C. B. P. 335. Yellow Ladies Bedstraw.*
2. **GALIUM (Mollugo)** foliis octonis ovato-linearibus subferratis patentissimis mucronatis, caule flaccido, ramis patentibus. Lin. Sp. Plant. 107. *Ladies Bedstraw with eight oval narrow leaves, which are spread open, sawed, and pointed, a weak stalk, and spreading branches. Mollugo montana latifolia ramosa. C. B. P. 333. Branching broad-leaved Mountain Mollugo.*
3. **GALIUM (Purpureum)** foliis verticillatis linearis-setaceis, pedunculis folio longioribus. Hort. Cliff. 34. *Ladies Bedstraw with narrow bristly leaves growing in whorls, and foot-stalks of the flowers longer than the leaves. Galium nigro-purpureum montanum tenuifolium. Col. Ecphr. 1. p. 298. C. B. P. 335. Narrow-leaved Mountain Ladies Bedstraw, with a black purple flower.*
4. **GALIUM (Glaucum)** foliis verticillatis linearibus pedunculis dichotomis, summo caule floriferis. Prod. Leyd. 256. *Ladies Bedstraw with narrow leaves growing in whorls, foot-stalks divided by pairs, and flowers growing at the top of the stalk. Galium saxatile glauco folio. Bocc. Mus. 2. p. 172. Rock Ladies Bedstraw with a gray leaf.*
5. **GALIUM (Rubrum)** foliis verticillatis linearibus patulis, pedunculis brevissimis. Hort. Cliff. 34. *Ladies Bedstraw with narrow leaves growing in whorls, and short foot-stalks. Galium rubrum. C. B. P. 335. Red Ladies Bedstraw.*
6. **GALIUM (Boreale)** foliis quaternis lanceolatis trineruiis glabris, caule erecto, seminibus hispidis. Flor. Lapon. 60. *Ladies Bedstraw with four smooth spear-shaped leaves having three veins, an upright stalk, and rough seeds. Rubia pratensis lævis acuto folio. C. B. P. 333. Smooth Meadow Madder with an acute leaf.*
7. **GALIUM (Album)** foliis verticillatis, linearis-lanceolatis, ramis floriferis longioribus. *Ladies Bedstraw with narrow spear-shaped leaves growing in whorls, and longer branches of flowers. Galium album vulgare. Tourn. Inst. R. H. 113. Common white Ladies Bedstraw.*
8. **GALIUM (Linifolium)** foliis linearis-lanceolatis glabris, caule erecto ramosissimo. *Ladies Bedstraw with seven narrow, smooth, spear-shaped leaves, and an upright branching stalk. Galium album linifolium. Barrel. Obser. 99. White Ladies Bedstraw with a Flax leaf.*
9. **GALIUM (Palustre)** foliis quaternis obovatis inæqualibus, caulibus diffusis. Flor. Suec. 119. *Ladies Bedstraw with four unequal oval leaves, and a diffused stalk. Galium palustre album. C. B. P. 335. White Marsh Ladies Bedstraw.*

The first of these plants (which is the sort commonly used in medicine) is very common in moist meadows, and in pasture grounds, in several parts of England. The other varieties are preserved in curious botanic gardens, but as they are plants of very little beauty, and are subject to spread very far, and over-run whatever plants grow near them, they are seldom cultivated in other gardens.

These sorts may any of them be propagated by parting their roots, which spread and increase very fast, either

in the spring or autumn, and will grow almost in any soil or situation, especially the first sort; the other sorts require a drier soil, but will all grow in any situation.

GALLERIES, are ornaments made with trees of various kinds, which are very common in all the French gardens, but are seldom introduced into the English gardens, especially since the taste for clipped trees has been exploded; but as there may be some who yet fancy these obsolete ornaments, I shall just mention the way of constructing them.

In order to make a gallery in a garden with porticoes and arches, a line must first be drawn of the length you design the gallery to be; which being done, it is to be planted with Hornbeam, as directed under the article **HORNBEAM**; which Hornbeam thus planted, is to be the foundation of the gallery.

The management of them is not very difficult; they require only to be digged about, and sheared a little when there is occasion.

The chief curiosity required is in the ordering the fore-part of the gallery, and in forming the arches.

Each pillar of the porticoes or arches ought to be four feet distant one from the other; the gallery twelve feet high, and ten feet wide, that there may be room for two or three persons to walk a-breast.

When the Hornbeams are grown to the height of three feet, the distance of the pillars well regulated, and the ground-work of the gallery finished, the next thing to be done is to form the frontispiece: to perform which you must stop the Hornbeam between two pillars at the height, and run up a trellis made for that purpose, which forms the arch.

As it grows up you must with your shears even those boughs that overshoot the others; in time they will grow strong, and may be kept in form by the shears. Portico galleries may be covered with Lime-trees.

GARCINIA. Lin. Gen. Plant. 526. The Mangosteen.

The CHARACTERS are,

The flower hath a one-leaved empalement, which is permanent. It hath four roundish concave petals, which spread open, and are larger than the empalement. It hath sixteen stamina which are erect, and form a cylinder, terminated by roundish summits. In the center is situated an oval germen, with scarce any style, but is crowned by a buckler-shaped plain stigma divided into eight parts, and is permanent. The germen afterward becomes a thick globular berry with one cell, including eight hairy fleshy seeds, which are convex and angular.

This genus of plants is ranged in the first section of Linnæus's eleventh class, intitled Dodecandria Monogynia, which includes those plants whose flowers have twelve stamina and one style.

We have but one SPECIES of this genus, viz.

GARCINIA (*Mangostana*.) Hort. Cliff. 182. *The Mangostan, or Mangosteen*. Arbor peregrina aurantio simili fructu. Clus. Exot. 12. *Foreign Tree with a fruit like the Orange*.

This tree grows naturally in the Molucca Islands, and also in the inland parts of New Spain, from whence I received perfect specimens, which were sent me by Mr. Robert Millar, who gathered them near Tolu, but did not know the tree. It rises with an upright stem near twenty feet high, sending out many branches on every side, which are placed opposite, and stand oblique to each other, and not at right angles; the bark of the branches is smooth, of a gray colour, but on the tender shoots it is green, and that of the trunk is of a darker colour and full of cracks: the leaves are of the spear-shape, and entire; they are seven or eight inches long, and about half so much in breadth in the middle, gradually diminishing to both ends, of a lucid green on their upper side, and of an Olive colour on their under, having a prominent midrib through the middle, with several small veins running from that to both sides of the leaf. The flower is like that of a single Rose, composed of four roundish petals, which are thick at their base, but are thinner toward their ends; they are of a dark

red colour. The fruit which succeeds the flower is round, the size of a middling Orange; the top is covered by a cap, which was the stigma on the top of the style, and remains to the top of the fruit, and is indented in rays to the number of six or seven; which are obtuse. The shell of the fruit is like that of the Pomegranate, but softer, thicker, and fuller of juice; it is green at first, but changes to a dark brown with some yellowish spots; the inside of the fruit is of a Rose colour, and divided into several parts by thin partitions, as in Oranges, in which the seeds are lodged, surrounded by a soft juicy pulp of a delicious flavour, partaking of the Strawberry and the Grape, and is esteemed one of the richest fruits in the world; the trees naturally growing in the form of Pyramolas, whose branches are well garnished with large shining green leaves; they have an elegant appearance, and afford a kindly shade in hot countries, therefore are worthy of cultivation, in all those countries where there is warmth enough to ripen the fruit. As there are but few of the seeds in these fruit which come to perfection (for the greatest part of them are abortive) so most of those which have been brought to Europe have failed; therefore the surest way to obtain the plants, is to sow their seeds in tubs of earth in the country, and when the plants have obtained strength, they may be brought to Europe; but there should be great care taken in their passage, to screen them from salt water and the spray of the sea, as also not to give them much water, especially when they are in a cool or temperate climate, for these plants are very impatient of wet. When the plants arrive in Europe, they should be carefully transplanted, each into a separate pot, filled with light kitchen-garden earth, and plunged into the tan-bed, observing to shade them from the sun till they have taken new root; then they must be treated in the same manner as other tender plants from hot countries.

GARDENS are distinguished into flower-gardens, fruit-gardens, and kitchen-gardens: the first, being designed for pleasure and ornament, are to be placed in the most conspicuous parts, i. e. next to, or just against the back front of the house; the two latter being principally intended for use and service, are placed less in sight.

Though the fruit and kitchen-gardens are here mentioned as two distinct gardens, and have by the French gardeners, as also by some of our own countrymen been contrived as such, yet they are now usually in one; and with good reason, since they both require a good soil and exposure, and will equally require to be placed out of the view of the house. And as it will be proper to inclose the kitchen-garden with walls, and to secure the gates, that no persons may have access to it, who have no business in it, for the sake of preserving the product, so these walls will answer the purposes of both. Moreover, in the disposition of the kitchen-garden, when it is properly divided into quarters, the planting of espaliers of fruit-trees round each of the quarters, will be of use in screening from the view the kitchen-herbs growing in the quarters; and, by that means, give an elegance to both parts, and save besides a great expence. The only objection which has been made to this of any consequence is, that the gardeners are too apt to crowd the borders near the walls with kitchen-herbs, whereby the trees are deprived of their nourishment; but this is in every gentleman's power to redress, by not suffering the borders to be thus crowded. But I shall treat more fully of this under the article of **KITCHEN-GARDEN**.

In the choice of a place to plan a garden in, the situation and exposure of the ground are the most essential points to be regarded; since, if a failure be made in that point, all the care and expence will in a manner be lost.

In a garden for pleasure, the principal things to be considered, are, 1st, the situation; 2dly, the soil, aspect, or exposure; 3dly, water; 4thly, prospect.

1st, Situation: this ought to be such an one as is wholesome, in a place that is neither too high nor too low; for if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees; if it be too low, the dampness of the ground, the vermin, and venomous creatures that breed in ponds and marshy places, add much to their insalubrity.

A situation on a rising ground, or on the side of a hill, is most happy, especially if the ground be not too steep; if the slope be easy, and in a manner imperceptible; if a good deal of level may be had near the house; and if it abounds with springs of water; for, being sheltered from the fury of the winds, and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hills, either from springs or rain, will not only supply fountains, canals, and cascades, for ornament, but when it has performed its office, will water the adjacent valleys, and render them fertile and wholesome, if it be not suffered to stagnate in them.

Indeed, if the declivity of the hill be too steep, and if the water be too abundant, a garden on the side of it may often suffer, by having the trees torn up by the torrents and floods; and the earth above tumbling down, the walls may be demolished, and the walks spoiled.

It cannot however be denied, that the situation on a plain or flat, has several advantages that the higher situation has not: floods and rains make no spoil; there is a continued prospect of champaigns, intersected by rivers, ponds, brooks, meadows and hills, covered with buildings or woods; and the level surface is less tiresome to walk on, and less chargeable, than that on the side of a hill; the terrace-walks and steps are not necessary; but the greatest disadvantage of flat gardens is the want of an extensive prospect, which rising grounds afford.

2dly, The second thing to be considered in chusing a plat for a garden, is a good earth or soil.

It is scarce possible to make a fine garden in a bad soil; there are indeed ways to meliorate ground, but they are very expensive; and sometimes, when the expence has been bestowed of laying good earth two feet deep over the whole surface, which for a large garden is an expence too great for most persons; and after this a whole garden has been ruined, notwithstanding the exposure has been southerly and healthful, when the roots of the trees have come to reach the natural bottom.

To judge of the quality of the soil, observe whether there be any Heath, Thistles, or such like weeds, growing spontaneously in it, for they are certain signs that the ground is poor. Likewise if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, of a faded green, and full of moss, or infested with vermin; if so, the place is to be rejected: but on the contrary, if it be covered with good Grass fit for pasture, then you may be encouraged to try the depth of the soil.

To know this dig holes in several places, six feet wide and four feet deep; if you find three feet of good earth it will do well, but less than two will not be sufficient.

The quality of good ground is neither to be stony, nor too hard to work; neither too dry, nor too moist; nor too sandy and light, nor too strong and clayey, which is the worst of all for gardens.

3dly, The third requisite is water. The want of this is one of the greatest inconveniencies that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry situation in summer; besides the usefulness of it in fine gardens, for making jets d'eau, canals, cascades, &c. which are the greatest ornaments of a garden.

4thly, The fourth thing required in a good situation is, the view and prospect of a fine country; and though this is not so absolutely necessary as water, yet

it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that is buried, as I may say, and has no kind of prospect, it will be not only disagreeable but unwholesome, by being too much shaded and obscured; as the trees will rather retain insalubrious damps, than communicate the refreshing air, that is so purifying to vegetable nature.

In short, a garden necessarily requires (besides the care of the gardener) the sun, a good soil, a full, or at least an open prospect, and water, the last above all; and it would be egregious folly to plant a garden where any of these are wanting.

Of the Designing or Manner of Laying out a Pleasure Garden.

The area of a handsome garden may take up thirty or forty acres, not more.

And as for the disposition and distribution of this garden, the following directions may be observed.

1st, There ought always to be a descent from the house to the garden not fewer than three steps, but if there are six or seven it will be better. This elevation of the building will make it more dry and wholesome, also from the head of these steps there will be a farther prospect or view of the garden.

In a fine garden, the first thing that should present itself to the sight, should be an open lawn of Grass, which, in size, should be proportionable to the garden; in a large garden it should not be less than six or eight acres; but in middling or small gardens, the width of it should be considerably more than the front of the house; and if the depth be one half more than the width, it will have a better effect. The figure of this lawn need not be regular, and if on the sides there are trees planted irregularly, by way of open grove, some of which may be planted forwarder upon the lawn than the others, whereby the regularity of the lawn will be broken, it will render it more like nature, the beauties of which should always be studied in the laying out and planting of gardens; for the nearer these gardens approach to nature, the longer they will please; for what is a garden, but a natural spot of ground dressed and properly ornamented? there are those who have erred in copying of what they call nature, as much as those who have drawn a whole garden into strait lines, great alleys, stars, &c. by bringing the roughest and most deformed part of nature into their compositions of gardens: as for instance, where the ground has been naturally level, they have at great expence, made hollows and raised mole-hills; so that the turf has been rendered not only more unpleasant to walk upon, but much worse to keep: and after all the pains that have been taken to ape nature, the whole is as easily discovered to be the work of art, as the stiffest slopes and the most finished parterres.

The great art in laying out of gardens, is to adapt the several parts to the natural position of the ground, so as to have as little earth to remove as possible; for this is often one of the greatest expences in making of gardens; and it may with truth be affirmed, that wherever this has been practised, nine times in ten it has proved for the worse; so that if instead of levelling hills to form large terraces, stiff slopes, and even parterres, as have been too often practised; or the sinking of hollows, and raising of hills, as hath by others been done; if the surface of the ground had only been smoothed and well turfed, it would have had a much better effect, and been more generally approved than the greatest number of these gardens, which have been made with an infinite expence both of time and money.

The next thing to be observed is, to contrive a dry walk, which should lead quite round the whole garden; for as gardens are designed to promote the exercise of walking, the greater the extent of this dry walk, the better it will answer the intent; since in bad weather, or in dewy mornings and evenings, when

when the fields are unpleasant or unsafe to walk over, these dry walks in gardens become useful and pleasant; and such walks, if laid either with gravel or sand, may lead through the different plantations, gently winding about in an easy natural way, which will be more agreeable than those long strait walks, which are too frequently seen in gardens.

But as the taste of designing gardens has of late altered from the former method, there are many persons who have gone into the opposite extreme; and in the forming of what they term serpentine walks, have twisted them about in so many short turns, as to render it very disagreeable to walk on them; and at the same time they strike the sight with as much stiffness and appearance of art, as any of the methods formerly practised. In short, the fewer turns there are in these walks, and the more they are concealed, the better they will please; and yet the turns being easy, and at great distances, will take off all the appearance of straitness. And here let me observe, that there can be no better, or more easy or natural method of laying out these walks, than by tracing the easy turns made on a road, where it bends by the track of the coach wheels.

These walks should be so contrived, as to lead into shade as soon as possible; as also into some plantations of shrubs, where persons may walk in private, and be sheltered from the wind; for no garden can be pleasing where there is want of shade and shelter.

Another thing absolutely necessary is, where the boundaries of the garden are fenced with walls or pales, they should be hid by plantations of flowering shrubs, intermixed with Laurels, and some other Evergreens, which will have a good effect, and at the same time conceal the fences, which are disagreeable, when left naked and exposed to the sight.

In situations where there is a good supply of water, the designer has room for adding one of the greatest beauties to the garden, especially if it will admit of a constant stream; for in such places, if the water is properly conducted through the garden, it will afford infinite pleasure; for although these streams may not be sufficient to supply a large surface, yet if these narrow rivulets are judiciously led about the garden, they will have a better effect than many of the large stagnating ponds or canals, so frequently made in large gardens; for where these pieces of water are large, if all the boundaries can be seen from one point of view, they cannot be esteemed by persons of judgment; and frequently these standing waters are brought so near the house, as to render the air damp and unhealthy; and many times they are so situated, as to occasion this inconvenience, and at the same time are not seen to any advantage from the house.

Where wildernesses are intended, these should not be cut into stars, and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design is trifling, but the walks should be noble, and shaded by tall trees; and the spaces of the quarters planted with flowering shrubs and Evergreens, whereby they will be rendered pleasant at all seasons of the year; and if there are hardy sorts of flowers (which will thrive with little care) scattered about near the sides of the walks, they will have a very good effect, in making a variety of natural beauties almost through the year.

The situation of these wildernesses should not be too near the house, lest they should occasion damps; therefore it is much better to contrive some open groves, through which there may be a communication under shade, from the house to these wildernesses, which are much the best when they are planted at the farthest part of the garden, provided they do not obstruct the view of fine objects.

Buildings are also very great ornaments to a garden, if they are well designed and properly placed; but the modern taste of crowding gardens with large useless buildings, I presume to think is censurable, with regard as well to propriety as expence.

Statues and vases are also very beautiful objects, but

these should by no means be placed too near each other; for when several of them appear at once, they fill and confound the eye, and lose the beautiful effect which they would have, if now and then one properly situated engages the sight.

What an expence might be spared, and applied to nobler purposes, if nature only were to be imitated, if simplicity were studied in this delightful art, rather than ostentation! for any thing may be said to be more of nature, than what we miscall grandeur.

Fountains are also very ornamental to a garden, if they are magnificently built, and where a constant supply of water can be obtained; but if they are meanly erected, or have not water to keep them constantly running, they should never be introduced into gardens, for nothing can be more ridiculous than to see a dry fountain; which, perhaps, at a great expence, may have water forced up, to supply it for an hour or two, and no more; and this perhaps not in dry seasons, when there is a general scarcity of water.

The same may also be observed of cascades, and other falls of water, which ought never to be contrived in gardens, where there cannot be a constant run of water; but where the situation of a garden is so happy, as to be naturally supplied with water, these falls and jets d'eau, may be rendered very great beauties, especially if they are well designed, and not made in the low mean taste, in which too many of those now in being appear, and where the water is made to fall over a parcel of regular steps of stone; but the fall should be in one sheet from top to bottom, where should be placed many large rough stones to break and disperse the water, and to increase the noise of the fall.

Where the ground is naturally uneven, and has gentle rises and falls, these may be so humoured in the laying out of the ground, as to be rendered very great beauties; but these inequalities of the ground must by no means be cut into regular stiff slopes, nor amphitheatres, as has been too much the practice: but if the knolls are properly planted with clumps of trees or shrubs, and the sloping sides smoothed and left in their natural position, they will have a much better effect, than can be given them by all the regular angles, lines, and flat slopes, which have been till of late, introduced by all the designers of gardens. The taste in laying out of gardens has greatly altered, and has been as greatly improved in England, in the compass of a few years; for, with the revolution, the Dutch taste of laying out gardens was introduced, which consisted of little more than flower-borders laid out in several scrolls of Box-work, clipped Evergreens, and such low expensive things; as also the walling round, and dividing the several parts of gardens by cross walls; so that a garden consisting of eight or ten acres, was generally divided by brick walls, into three or four separate gardens; and these were reduced to exact levels, having many gravel-walks, and the borders on each side crowded with clipped trees and Evergreen hedges, dividing these small inclosures again; so that the first making and planting of these small gardens was attended with a greater expence, as was the keeping of them afterward, than gardens of six times the extent, when designed after nature.

Whether this taste so universally prevailed in England, in complaisance to his late Majesty King William, or was owing to the low grovelling taste of those persons, who had the designing of most of the English gardens, it is difficult to determine; but it is very certain, that the gentlemen, at that time, attended very little themselves, to the disposition of their gardens, but were contented to leave the whole direction of them to persons of the meanest talents that ever professed the art; so that soon after, when another taste prevailed, these gardens were almost totally demolished, and it would have been well, if a good, that is to say, a natural taste had succeeded the other; but this was not the case; for though a more open and extensive way of laying out gardens was introduced, yet this was lit-

G A R

tle more than copying after the French, whose taste was in making long avenues, strait walks, stiff regular slopes, cabinets, fret-work, tall hedges cut into various shapes, jets d'eau, fountains, &c. so that there was little of nature studied; but, on the contrary, all the geometrical figures introduced in wilderness-work, as also in the parterres, and other compartments of the garden: nor is it so much to be wondered at, that this taste prevailed in France, when the designs of all the principal gardens were there formed by architects, who were as studious to have the symmetry of the opposite, or corresponding part of the garden, as exact as the apartments of a habitation; nor has length of time, nor the improvements already made in other countries, amended their taste, or convinced them of its absurdity.

As the gardens of Versailles, Marli, and others, were extolled for their magnificence, so the plans of them were almost universally copied; the designers, or imitators rather, only varying the parts according to the situation or figure of the ground; and this was practised for several years, at a time, when great sums of money were expended in gardens, which might have rendered this country the most beautiful of any in Europe, had a natural taste then prevailed in the designing of gardens; which is the more to be lamented, as the plantations then made, have been many of them rooted out, to make way for the alterations and improvements which have been since introduced. Many persons, I am sensible, will have it, that, in the designs of gardens, the taste should alter from time to time, as much as the fashion of apparel; but these cannot be persons of judgment; for wherever there are natural beauties in a country, they will always please persons of real knowledge; and frequently it is observed, that persons of but little skill in the art of gardening, are struck with these beauties without knowing the cause; therefore where the beautiful parts of nature are justly imitated in gardens, they will always be approved by judicious persons, let the taste of gardening alter as it will.

When trees have been long growing in a garden, nothing can be more disagreeable than to have them destroyed, to alter the garden according to the fashion of the time, because it requires much time to bring up trees to such a height as to afford shade and shelter; and, as time is precious, so, where the disposition of the garden is altered; there should be great attention given to the preservation of all the good trees, wherever they can be either useful or ornamental.

There is another essential part of gardening, which cannot be too much considered by persons who design gardens, which is that of adapting the several sorts of trees and shrubs, to the situation and soil of the garden, as also to allow the trees a proper share of room; but, however necessary this will appear, yet very few persons have made this their study, in so much that when one views many modern gardens, and sees the great number of trees and shrubs, which are crowded into them, one would be induced to believe, that private interest has had a greater influence than any other motive, with the designers. Indeed this fault may often be ascribed to the master, who, perhaps, is too much in haste for shade and shelter, so will have three or four times the number of trees and shrubs planted as should have been, or that can remain long without injury, where the plantations succeed; and to this over-haste are owing the miserable plantations of large trees, so often seen in gardens and parks, where trees of all sorts, and of any age are taken out of woods, hedge-rows, &c. and removed at a great expence to stand and decay annually, till they become so many dead sticks, than which nothing can be a more disagreeable sight to the owner; who, after an expectation for several years, attended with an expence of watering, digging, and cleaning, finds himself under a necessity either of replanting, or giving up the thoughts of having any. Numbers of persons have indeed amused themselves with the hopes of success, by seeing these

G A R

new planted trees put out branches for a year or two, which they generally do; but in three or four years after, instead of making a progress, they begin to decay at the top, and continue to do so gradually, until they quite perish, which, perhaps, may not happen in eight or ten years, especially if no severe winter, or very dry summer, intervenes, either of which generally proves fatal to these plantations; so that persons may be led on with hopes, for so many years, in the best part of their lives, when there is a certainty of their failing, or at least of their never increasing in size; but of this I shall treat more fully in the article of PLANTING, and shall proceed.

In the business of designs, a mean and pitiful manner should be studiously avoided, and the aim should be always at that which is noble and great, not to bring too many little things into a garden, nor to make small pieces of water, narrow walks, &c. especially in large gardens; for it is much better to have a few great things, than four times the number of small ones, which are trifling. In small gardens there is more excuse for this, nor indeed would it be right, to have either large lawns, broad walks, or large pieces of water in such; but yet even in these there ought to be a medium, and persons should never attempt to crowd too many things in these, whereby the whole will appear only as a mean and trifling model of a large garden. Before the design of a garden is entered upon, it ought to be considered, what it will be in twenty or thirty years time, when the trees and shrubs are grown up, and spread; for it often happens, that a design, which looks handsome when it is first planted, and in good proportion, in process of time becomes so small and ridiculous, that there is a necessity either of altering or totally destroying it.

The general distribution of a garden, and of its parts, ought to be accommodated to the different situations of the ground, for a design may be very proper for a garden on a perfect level, which will by no means do for one where there are great inequalities in the ground; so that, as I have before intimated, the great art of designing is, in properly adapting the design to the situation, and contriving to save the expence of removing earth, to humour the inequalities of the ground, to proportion the number and sorts of trees and shrubs to each part of the garden, and to shut out, from the view of the garden, no objects that may become ornamental.

There are, besides these, many other rules relating to the proportions, conformity, and disposition of the different parts and ornaments of gardens, of which more may be seen under their several articles.

GARDENIA. See JASMINUM.

GARIDELLA. Tourn. Inst. R. H. 655. tab. 430. Lin. Gen. Plant. 507. [This plant was so named by Dr. Tournefort, in honour of Dr. Garidel, who was professor of physic, at Aix, in Provence.]

The CHARACTERS are,

The flower hath a small, oblong, erect empalement of five leaves; it hath no petals, but five oblong equal nectariums occupy their place; these are bilabiate. The outer part of the under lip is bifid and plain; the interior part of the upper lip is short and single. The flower hath eight or ten awl-shaped stamina, which are shorter than the empalement, and are terminated by obtuse erect summits. In the center is situated three germina, which are oblong, compressed, and sharp-pointed, having no styles, but crowned by simple stigmas; these become three oblong compressed capsules with two valves, inclosing several small seeds.

This genus of plants is ranged in the third section of Linnæus's tenth class, which includes those plants whose flowers have ten stamina and three germen.

We know but one SPECIES of this genus, viz.

GARIDELLA (*Nigellastrum*.) Hort. Cliff. 170. Garidella foliis tenuissime divis. Tourn. Garidella with very narrow divided leaves; and the *Nigella Cretica* folio Fœniculi. C. B. P. 146. Fennel-flower of Crete with a Fennel leaf.

This plant is very near akin to the *Nigella*, or Fennel-flower, to which genus it was placed by the writers on botany before Dr. Tournefort, and was by him

G A U

him separated from it, as differing in the form of the flower.

It grows wild in Candia, and on mount Baldus, in Italy, as also in Provence, where it was discovered by Dr. Garidel, who sent the seeds to Dr. Tournefort, for the Royal Garden at Paris.

This is an annual plant, which rises with an upright stalk a foot high, dividing into several slender branches, garnished at their joints with very slender leaves like those of Fennel. The stalks are terminated by one small flower, of a pale herbaceous colour, which is succeeded by three capsules, each containing two or three small seeds. It flowers in June and July, and the seeds ripen in September. It is propagated by seeds, which should be sown in autumn, on a bed or border of light fresh earth, where the plants are designed to remain (for they seldom thrive if they are transplanted;) when the plants are come up, they must be carefully cleared from weeds, and where they are too close, they must be thinned, leaving them about four or five inches apart; this is all the culture the plants require, and if the seeds are permitted to scatter, the plants will come up without any farther care.

GAULTHERIA.

The CHARACTERS are,

It hath a double permanent empalement; the outer has two oval, concave, short leaves; the inner has one bell-shaped leaf cut into five segments; the flower has one oval petal, cut half-way into five segments, which are reflexed; it has ten awl-shaped nectarii, which are short, surrounding the germen and stamina, and ten awl-shaped incurved stamina inserted to the receptacle, terminated by bifid horned summits, and a roundish depressed germen, supporting a cylindrical style, crowned by an obtuse stigma; the germen afterward becomes an obtuse five-cornered capsule, having five cells, fastened to the interior empalement, which turns to a berry open at the top, filled with hard angular seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flower having ten stamina and one style.

We know but one SPECIES of this genus, viz.

GAULTHERIA (*Procumbens.*) Amœn. Acad. 3. p. 14. *Trailing Gaultheria.* Vitis Idæa Canadensis, pyrolæ folio. Tourn. Inst. 608. *Canada Wortle-berry with a winter-green leaf.*

This plant grows naturally in several parts of North America upon swampy ground, so is with difficulty preserved in the English gardens. The branches of this trail upon the ground, and become ligneous, but never rise upward; they are garnished with oval entire leaves, placed alternate; the flowers are produced on the side of the branches; they are of an herbaceous colour, so make little appearance, and very rarely are succeeded by fruit in England.

The only method in which I have succeeded to keep this plant, was by planting of it in a pot, filled with loose undunged earth, placing it in the shade, and frequently watering it; with this management I have kept the plant alive three years, and have had flowers but no fruit.

GAURA.

The CHARACTERS are,

It hath an empalement of one leaf, which falls off, with a long cylindrical tube, having four oblong glands fastened to it; the upper part is cut into four oblong segments, which are reflexed. The flower hath four oblong rising petals, which are broad at the top but narrow at their base, sitting upon the tube of the empalement; and eight upright slender stamina which are shorter than the petals, and a nectarious gland between the base of each, with oblong moveable summits. The oblong germen is situated under the flower, supporting a slender style the length of the stamina; crowned by four oval spreading stigmas; the flower is succeeded by an oval four-cornered compressed capsule, containing one oblong angular seed.

This genus of plants is ranged in the first section of Linnæus's eighth class, intitled Octandria Monogynia, the flower having eight stamina and one style.

G E N

We know but one SPECIES of this genus, viz.

GAURA (*Biennis.*) Amœn. Acad. 3. p. 26. *Gaura.* *Lyfimachia chamænerio similis floridana, foliis nigris punctis capsulis carinatis in ramulorum cymis.* Pluk. Amalth. 139. tab. 428. f. 1.

This is a biennial plant, which grows naturally in Virginia and Pennsylvania: the stalk rises four or five feet high, sending out several branches, which are garnished with oblong, smooth, pale, green leaves, sitting pretty close. The flowers are produced in close tufts at the end of the branches; they are composed of four oblong petals, of a pale Rose colour, irregularly placed, having eight stamina surrounding the style. The flowers appear in September, and when the autumn proves favourable, the seeds will ripen toward the end of October.

If the seeds of this plant are sown on open borders soon after they are ripe, they will more certainly succeed than when they are sown in the spring. When the plants come up, they must be kept clean from weeds; and if they are too close, some of them should be drawn out, and planted in a bed to allow room for the other to grow; in the autumn they should be all transplanted to the place where they are designed to stand for flowering and perfecting their seeds, and will require no other culture but to support their branches to prevent the autumnal winds from breaking them down.

GENERATION is, by naturalists, defined to be the act of procreating and producing a thing which before was not; or, according to the schoolmen, it is the total change or conversion of a body into a new one, which retains no sensible part or mark of its former state.

Thus we say, fire is generated, when we perceive it to be where before there was only wood, and other fuel, or when the wood is so changed, as to retain no sensible character of wood; in the like manner a chick is said to be generated, when we perceive a chick, where before was only an egg, or the egg is changed into the form of a chick.

In generation there is not properly any production of new parts, but only a new modification or manner of existence of the old ones, and thus generation is distinguished from creation.

Generation also differs from alteration, in that in alteration the subject remains apparently the same, and is only changed in its accidents or affections, as iron, which before was square, is now made round; or when the same body which is well to-day, is sick to-morrow. Again: generation is the opposite to corruption, which is the utter extinction of a former thing; as, when that which before was an egg, or wood, is no longer either the one or the other; whence it appears, that the generation of one thing is the corruption of another.

The Peripateticks explain generation by a change or passage from a privation, or want of a substantial form, to the having such a form.

The moderns allow of no other change in generation, than what is local; and, according to their notion, it is only a transposition, or new arrangement of parts; and, in this sense, the same matter is capable of undergoing an infinite number of generations.

As for example: A grain of Wheat, being committed to the ground, imbibes the humidity of the soil, becomes turgid, and dilates to such a degree, that it becomes a plant; and, by a continual accession of matter, by degrees, ripens into an ear, and at length into a seed; this seed, when ground in a mill, appears in the form of a flour, which, being mixed up with water, makes a paste, of which bread is generated by the addition of yeast, and undergoing the operation of fire, i. e. by baking; and this bread being comminuted by the teeth, digested in the stomach, and conveyed through the canals of the body, becomes flesh, or, in other words, flesh is generated.

Now the only thing effected in all this series of generation, is a local motion of the parts of the matter, and their settling again in a different order; so that where-

GEN

wherever there is a new arrangement, or composition of the elements, there is, in reality, a new generation, and thus generation is reduced to motion.

Generation is more immediately understood of animal and vegetable bodies from seed, or the coition of others of different sexes, but of the same genus or kind.

Mons. Perrault, and some of the modern naturalists after him, maintained, That there is not properly any new generation, that God created all things at first, and that what is by us called generation, is no more than an augmentation and expansion of the minute parts of the body of the seed; so that the whole species, which are afterwards produced, were, in reality, all formed at the first, and inclosed therein, to be brought forth and exposed to view in time, and according to a certain order and œconomy.

And accordingly Dr. Garden says, It is most probable, that the stamina of all the plants and animals that have been formed, ab origine mundi, by the Almighty Creator, within the first of each respective kind; and he who considers the nature of vision, that it does not give us the true magnitude, but only the proportion of things; and that which seems to our naked eye but a point, may truly be made up by as many parts as seem to be in the whole universe, will not think this an absurd or impossible thing.

Dr. Blair, treating of the generation of plants, says, That when Almighty God created the world, he so ordered and disposed of the materies mundi, that every thing produced from it should continue so long as the world should stand. Not that the same individual species should always remain; for they were, in process of time, to perish, decay, and return to the earth, from whence they came; but that every like should produce its like, every species should produce its own kind, to prevent a final destruction of the species, or the necessity of a new creation, in order to continue the same species upon earth, or in the world.

For which end he laid down certain regulations, by which each species was to be propagated, preserved, and supported, till, in order, or course of time, they were to be removed hence; for, without that, those very beings, which were created at first, must have continued till the final dissolution of all things, which Almighty God of his infinite wisdom did not think fit.

But, that he might still the more manifest his omnipotence, he set all the engines of his providence to work, by which one effect was to produce another by the means of certain laws, or rules laid down for the propagation, maintenance, and support of all created beings; this his divine providence is called nature, and these regulations are called the laws, or rules of nature, by which it ever operates in its ordinary course, and whatever exceeds from that is said to be preternatural, miraculous, or monstrous.

Moses, in his account of the creation, tells us, that plants have their seeds in themselves, in these words: And God said, Let the earth bring forth grass, the herb yielding seed, and the fruit-tree yielding fruit, after his kind, whose seed is in itself upon the earth.

The antients, indeed, distinguished the generation of animals into two kinds, i. e. into regular, called univocal; and anomalous, called also equivocal, or spontaneous.

The first was effected by parent animals of the same kind, as that of men, birds, beasts, &c. The second they supposed to be effected by corruption, the sun, &c. as that of insects, frogs, &c. but this latter is now generally exploded.

Many, indeed, have essayed to treat of the generation of animals, but few have been able to give that satisfactory account of it that were to be wished for, and far fewer yet have been able to treat of the generation of plants as it ought to be; for that which still kept them in the dark, was,

First, That though there were two different sexes in animals, by whose mutual assistance the species was

GEN

propagated, yet there was no such thing then known in plants.

Secondly, That though it can now be made appear, that every animal is produced by univocal generation, i. e. from an egg, and not by corruption, &c. as most of the antients imagined the insects were; yet there are still those who maintain, that those which they call imperfect plants, are the product of a certain rottenness in the earth.

The generation of plants bears a close analogy to that of some animals, especially such as want local motion, as muscles, and other immoveable shell-fish, which are hermaphrodite, and contain both the male and female organs of generation.

The flower of a plant is found to be the pudendum, or principal organ of generation; but the use of so much mechanism, and so many parts, has been but little known till of late years.

The flower of a Lily consists of six petala, or flower-leaves, from the bottom of which, in the middle, arises a kind of tube, called by Tournefort, the pistillum, and by Dr. Linnæus the style; this rests upon the germen, which is the female organ of generation; round this are placed pretty fine threads, called the stamina, or filaments; these stamina arise likewise from the bottom of the flower, and terminate at the top in little summits, called by some apices, which are replete with a fine dust, called farina; these are the male organs of plants.

This is the general structure of the flowers of plants, although they are infinite ways diversified, and to such a degree, that some have no sensible pistil, and others want the stamina; others again have the stamina, but want the apices, and some plants exceed all others in this, that they have no visible flowers; but if it be allowed, that this before-mentioned is the most common structure of flowers, it will follow, that these parts that seem wanting are usually only less apparent, or are situated in different plants, or in different parts of the same plant.

The fruit is usually at the base of the pistillum, so that when the pistillum falls with the rest of the flower, the fruit appears in the stead of it; but oftentimes the pistillum is the fruit itself, but still they have both the same situation in the center of the flower, and the petala, or flower-leaves, which are disposed around the little embryo, seem to be designed only to prepare a fine juice in the little vessels, for the support of it during the little time that they last, and it requires; but some suppose the chief use of them to be to defend the pistillum, &c.

The apices of the stamina are small capsulæ, or bags, full of a farina, or dust, which falls out when the capsula grows ripe, and bursts.

Mons. Tournefort supposed this dust to be only an excrement of the food of the fruit, and the stamina to be nothing but excretory ducts, which filtrated this useless matter, and thus discharged the embryo; but Mr. Morland, Mr. Geoffroy, and others, find nobler uses for this dust; on their principle the stamina, with the apices and farina, make the male part of the plant, and the pistil, the female.

Mr. Morland says, It hath been long ago observed, that there is in every particular seed a seminal plant conveniently lodged between the two lobes, which constitute the bulk of the seed, and are designed for the first nourishment of the tender plant.

But the admirable Dr. Grew, to whose generous industry, and happy sagacity, we are indebted for the best improvements of this part of knowledge, is the only author I can find, who hath observed that the farina, or fine powder, which is, at its proper season, shed out of those thecæ, or apices seminiformes [i. e. seed-forming cases] which grow at the top of the stamina, doth some way perform the office of male sperm. But herein, I think, he falls short, in that he supposes them only to drop upon the outside the uterus, or vasculum seminale, and to impregnate the included seed by some spirituous emanations, or energetical imprints.

That

That which is now subjected to the disquisitions and censure of such whose exquisite skill constitutes them judges of such performances, is, Whether it may not be more proper to suppose, that the seeds which are lodged in the proper involucra, are at the first unimpregnated ova (or eggs) as of animals; that this farina is a congeries of seminal plants, one of which must be conveyed into every ovum before it can become prolific; that the stylus, in Mr. Ray's language, or the upper part of the pistillum, in Mr. Tournefort's, is a tube designed to convey these seminal plants into their nests in the ova; that there is so vast a provision made, because of the odds there are, whether one, of so many, shall ever find its way into, and through so narrow a conveyance.

To make this supposition the more credible, I shall lay down the observations I have made upon the situation of these stamina, and the stylus, in some few species of plants.

First, In the *Corona Imperialis*, where the uterus, or vasculum feminine of the plant stands upon the center of the flower; and from the top of this ariseth the stylus, the vasculum feminine and stylus together representing a pistillum.

Round this are placed six stamina; upon the ends of each of these are apices, so artfully fixed, that they turn every way with the least wind, being in height almost equal to the styles about which they play, and which in this plant is manifestly open at the top, as it is hollow all the way; to which we must add, that upon the top of the stylus there is a sort of tuft, consisting of pinguid villi, which I imagined to be placed there to catch and detain the farina, as it flies out of the thecae; from hence, I suppose, the wind shakes it down the tube, till it reach the vasculum feminine.

In the *Caprifolium*, or *Honeysuckle*, there rises a stylus from the rudiments of a berry, into which it is inserted to the top of the monopetalous flower; from the middle of which flower are sent forth several stamina, that shed their farina out of the cases upon the orifice of the stylus, which, in this plant, is villous or tufted, upon the same account as in the former.

In *Allium*, or common *Garlic*, there arises a tricoccus uterus, or seed-vessel; in the center of which is inserted a short stylus, not so high as the apices, which thus over-topping it, have the opportunity of shedding their globules into an orifice more easily; for which reason, I can discern no tuft upon this (as in the former) to insure their entrance, that being provided for by its situation just under them.

The reader, I hope, will excuse me, if I present him now with some such reasonings or reflections as the foregoing account doth suggest, and will support; and I cannot but hope to persuade those that are candid, that I have assigned to the several parts of the flowers I have mentioned, their true and real use.

For nothing can be more natural than to conclude, that where a fine powder is curiously prepared, carefully repositied, and shed abroad at a peculiar season, where there is a tube so placed as to be fit to receive it, and such care in disposing this tube, where it doth not lie directly under the cases that shed the powder, it hath a particular apparatus at the end, to insure its entrance.

Nothing can be more genuinely deduced from any premises, than it may from this, that this powder, or some of it, was designed to enter this tube. If these stamina had been only excretory ducts, as has been hitherto supposed, to separate the grosser parts, and leave the juice designed for the nourishment of the seed more reserved, what need was there to lodge these excrements in such curious repositories? They would have been conveyed any where, rather than where there was so much danger of their dropping into the seed-vessel again, as there is here.

Again: the tube, over the mouth of which they are shed, and into which they enter, leads always directly into the seed-vessel.

To which we must add, that the tube always begins to die when these thecae are emptied of their contents; if they last any longer, it is only whilst the globules, which enter at their orifice, may be supposed to have finished their passage. Now, can we well expect a more convincing proof of these tubes being designed to convey these globules, than that they wither when there are not more globules to convey.

If I could now shew, that the ova, or unimpregnated seeds, are ever to be observed without this seminal plant, the proof would arise to a demonstration; but having not been so happy as to observe this, I shall content myself at present with suggesting, that hence one would conclude, that the petala of the flower were rather designed to sever superfluous juices from what was left to ascend in the stamina, than the stamina to perform this office, either for them, or the unimpregnated semina, and observe the analogy between animal and vegetable generation, as far as was necessary there should be an agreement between them. I shall recommend the enquiry to those gentlemen who are masters of the best microscopes, and address in using them; though, in the mean time, I have made some steps toward a proof of this sort, and have met with some such hints, as make me not despair of being able, in a short time, to give the world even this satisfaction. For, not to insist upon this, that the seminal plant always lies in that part of the seed which is always nearest to the insertion of this stylus, or some propagation of it into the seed-vessels, I have discovered in Beans, Peas, and Kidney-beans, just under one end of that we call the eye, a manifest perforation, (discernible by the grosser sort of magnifying glasses) which leads directly to the seminal plant, and at which I suppose the seminal plant did enter; and, I am apt to think, the Beans or Peas that do not thrive well, may be found destitute of it.

But I must now proceed to describe some other plants, whereby it will appear, that there is a particular care always exercised to convey this powder, so often mentioned, into a tube, which may convey it to the ova.

Now, in leguminous plants, if we carefully take off the petala of the flower, we shall discover the pod, or siliqua, closely covered with an involving membrane, which, about the top, separates into nine stamina, each fraught with its quantity of farina; and these stamina closely adhere to the style, which is observable at the end of that tube, which here also leads directly to the pod; it stands not upright, indeed, but so bent, as to make near a right angle with it.

In *Roses* there stands a column, consisting of many tubes closely clung together, though easily separable, each leading to their particular cell, the stamina in a great number placed all round about.

In *Tithymalus*, or *Spurge*, there rises a tricoccus vessel, that, whilst it is small, and not easily discernible, lies at the bottom till it is impregnated, but afterwards grows up, and stands so high upon a tall pedicle of its own, as would tempt one to think, that there were to be no communication betwixt this and the apices.

In the *Strawberries* and *Raspberries*, the hairs which grow upon the ripe fruit (which, I suppose, may be surprising to some) are so many tubes leading each to their particular seed; and therefore we may observe, that in the first opening of the flower there stands a ring of stamina, within the petala, and the whole inward area appears like a little wood of these hairs or pulp, which, when they have received and conveyed their globules, the seeds swell, and rise in a carneous pulp. Thus far Mr. Morland.

We may observe a vessel at the bottom of the pistil of the *Lily*, which vessel we may call the uterus, or womb, in which are three ovaries filled with little eggs, or rudiments of seed found in the ovaria, which always decay, and come to nothing, unless impregnated with the farina of the same plant, or some other of the same kind; the stamina also serve for the conveyance of the male seed of the plant to be per-

fects in the apices, which, when ripe, burst forth in little particles like dust; some of them fall into the orifice of the pistil, and are either conveyed thence into the utricle, to fecundify the female ova, or lodged in the pistil, where, by their magnetic virtue, they draw the nourishment from the other parts of the plant into the embryos of the fruit, making them swell, grow, &c.

In flowers that turn down, as the Cyclamen, and the Imperial Crown, the pistil is much longer than the stamina, that their dust may fall from their apices in sufficient quantities on the pistil, for the business of impregnation.

Mr. Geoffroy assures us, That in all the observations he had made, the cutting off the pistil before it could be impregnated by the farina, actually rendered the plant barren for the season, and the fruit abortive.

In many kinds of plants, as the Oak, Pine, Willow, &c. the flowers, Mr. Geoffroy observes, have their stamina and apices, whose farina may easily impregnate the rudiments of the fruit, which are not far off.

Indeed there is some difficulty in reconciling this system with a certain species of plants, which bear flowers without fruit; and another species of the same kind and denomination, which bear fruit without flowers; such are the Palm, Hemp, Hop, Poplar, &c. which are hence distinguished into male and female; for how should the farina of the male here, come to impregnate the ova of the female?

This difficulty Mr. Geoffroy solves, by supposing the wind to be the vehicle that conveys the male dust to the female uterus, which is confirmed by an instance of Jovianus Potanus, of a single female Palm-tree growing in a forest, which never bore fruit, till, having risen above the other trees of the forest, and being then in a condition to receive the farina of the male by the wind, it began to bear fruit in abundance.

As to the manner wherein the farina fecundifies, Mr. Geoffroy advances two opinions:

First, That the farina being always found of a sulphureous composition, and full of subtil and penetrating parts (as appears from its sprightly odour) which, falling on the pistils of the flowers, there resolves, and the subtilest parts of it, penetrating the substance of the pistil, excite a fermentation, which putting the latent juices of the young fruit in motion, occasions the parts to unfold the young plant that is inclosed in the embryo of the seed.

In this hypothesis, the plant in miniature is supposed to be contained in the seed, and to want only a proper juice to unfold its parts, and to make them grow.

The second opinion is, That the farina of the male plant is the first germ or semen of the new plant, and stands in need of nothing to enable it to grow or unfold, but a suitable nidus with the juice it finds prepared in the embryo of the seed or ovary.

It may be observed, that these two theories of vegetable generation bear a strict analogy to those two of animal generation, viz. either that the young animal is in the semen masculinum, and only stands in need of the juice of the matrix to cherish and bring it forth; or that the female ovum contains the animal, and requires only the male seed to excite a fermentation.

Mr. Geoffroy rather makes the proper seed to be in the farina, inasmuch as the best microscopes do not discover the least appearance of any bud in the little embryos of the grains, when they are examined, before the apices have shed their dust.

In leguminous plants, if the petala and stamina be removed, and the pistil, or that part which becomes the pod, be viewed with the microscope before the flower be open, those little green-transparent vesiculæ, which are to become grains, will appear in their natural order, yet still shewing nothing else but the mere coat, or skin of the grain.

If you continue to observe the flowers as they advance for several days successively, you will find them to swell, and, by degrees, to become replete with a limpid liquor; in which, when the farina comes to be shed, and the leaves of the flower to fall, there may be observed a little greenish speck, or globule, floating about at large.

There is not at first any appearance of an organization in this little body; but in time, as it grows, you may begin to distinguish two little leaves like two small horns; as the little body grows, the liquor diminishes insensibly, till at length the grain becomes quite opaque; and upon opening it, the cavity will be found filled with a young plant in miniature, consisting of a little germ, or plantula, a little root, and the lobes of the Bean, or Pea.

The manner wherein this germ of the apex enters the vesicula of the grain, is not very difficult to determine: for, besides that the cavity of the pistil reaches from the top to the embryos of the grains, or those vesiculæ, have a little aperture corresponding to the extremity of the cavity of the pistil, so that the small dust, or farina, may easily fall, or find an easy passage in the aperture in the mouth of the vessels, which is the embryo of the grain.

The aperture, or cicatricula, is much the same in both grains; and it is easily observed in Peas, Beans, &c. without a microscope.

Dr. Patrick Blair, treating of the generation of plants, says, That a vegetative life is common to them, as well as animals; and that the propagation or production of the species is the effect of the vegetative, not the sensitive life in animals, as well as in plants; and that if there be a necessity of the concurrence of two different sexes in animals, at the beginning or generating of the species, the same necessity must be in plants too; for as a cow, a mare, a hen, a she-reptile, an insect, &c. cannot produce an animal without the male, no more can it be supposed, that a plant can produce fertile seed without the concurrence of the male plant, or the male parts of the plant.

Mr. Ray says, That he will not deny, that both trees and herbs may produce fruit, and even come to maturity, without the male seed being sprinkled upon them. For though most birds do not lay eggs without congress of the male, yet the hen often does it without copulating with the cock, but then these eggs are barren and wind eggs; just so, though a female plant may produce seed of itself, yet that seed is never fertile. For,

First, As the work of generation in animals does not proceed from their animal or sensitive life but from their vegetative, which being the same as in plants, that operation must be performed after the same manner in both; therefore, as there is a necessity of two different sexes in animals, it must be so too in plants.

Secondly, As passive seminal matter in female animals cannot be productive or fertile of itself, without being impregnated, animated, or its particles set in motion and dilated by the active principles of the male seminal matter; neither can the female seed in plants be rendered fertile, until it be impregnated by the farina fecundans from the male parts of the plants.

As to the flowers of plants, if they were not assisting to, or if there were not some extraordinary use from them in the perfection of the seed, they would not be so often observed upon plants as they are. But since there is no fruit or seed without a previous flower; and since where the one is obvious the other is conspicuous, and since one is scarce to be observed with the naked eye, neither is the other; this implies a relation between them, that the one of them is not to be expected without the other.

It is true, there may be flowers upon a plant, where the fruit is seldom seen, especially in these northern climates; such as the Pervinca, the *Nymphæa alba minima*, and several others; where the plant exhausts the

the nutritious juice, in pushing forth tendrils or creeping roots, which so weaken the plants, as not to be able to bring the fruit to perfection; but there is no fruit or seed to be seen, unless a flower has been sent as a messenger before it, to give notice of its approach; though it is not always upon the same plant, yet it is still upon some other plant of the same species; for the flowers are to be seen upon distinct plants, different branches, or different parts of the branch from the fruit, in the *Abies*, *Corylus*, *Nux Juglans*, &c. the *Mercurialis*, *Spinachia*, &c.

But the fruit never appears, or never begins to increase upon these plants, till the flower is spent and gone; therefore they must serve for another use, than to be merely ornamental; for if that were their principal use, they would be always conspicuous, which they are not for the most part in apetalous flowers; and they would always be to be seen, and never be hid; which is not so in the *Asarum*, *Hydrocotyle*, &c. where, though the flower is large enough in proportion to the fruit, yet it is not to be seen, unless the leaf be turned up, and both flower and fruit be narrowly searched for.

The *Frumenta* and *Gramina* have their staminate flowers; yet in some of them the flower is seldom to be seen, unless the spike be shaken; and then the apices will appear.

The *Polypodium*, and other capillary plants, have regular flowers, which precede the minute capsulae or seed-vessels, but neither of them are conspicuous without a microscope.

From these instances it appears, that the flowers are not constantly a guard to preserve the tender embryos from the injuries of the air, for then the flowers must always have been upon the same pedicle with the fruit.

Therefore, since the appearance of the flower is the first step towards the production of the seed, whether both be upon the same pedicle or not, it necessarily follows, that the one must contribute towards the bringing of the other to perfection.

The ancients taking notice, that several plants did produce flowers and had no seeds, and that other plants of the same species, and sown from the same seed, did produce the seed without a previous flower, they were ready to call the one male, and the other female, without any notion that the one was assisting to the other; for they looked upon such flowers to be only barren; and therefore they called those which had flowers female, and those that produced the fruits, male plants. Thus *Mercurialis* is called *Spicata Foemina*, and *Testiculata Mas*. That which produces the fruit must needs be the female, as the female animal brings forth the foetus; therefore the *testiculata* must needs be the female, and the *spicata* the male.

Wherever the plants are annual, these with the flowers, and such as have the seed, are always near to each other; but where the root is perennial, and where the plant is more frequently propagated by the root than the seed, the case alters; for there being no need of the seed to propagate the plant, there is the less need of the flower to be nearer to the plant which produces the seed.

So the *Spinachia* and the *Lupulus* are frequently seen to grow, to produce the seed, and the other the squamous fruit; when the plants which produce the male flowers of the one or the other, are at some distance. And this is so far from being an objection against the necessity of two sexes in plants as well as in animals, that it is an argument to confirm it; for it shews the wonderful contrivances in order to preserve the species, when the ordinary means of propagating it by the seed cannot be so conveniently attained.

These, and more that might be produced, being evident proofs of two sexes in plants, as well as in animals, we shall in the next place, give some experiments to confirm this in a negative way, as have been already done in a positive.

When plants have been deprived of their male flowers,

or male parts in the flower, they either produced no seed at all, or if they did, they became abortive, dried up, or dwindled away; or though the seeds did come to perfection, they were barren, or did not produce.

Experiment 1. Mr. Geoffroy having cut off all the staminate tufts of male flowers from the top of the stalk in the *Maiz* or *Turkey-wheat*, as soon as they appeared, and before the spike loaded with the embryos of the semen had put forth from the axils of the leaves, several of these embryos decayed and dried up after they were pretty big; but some grains upon their pedicles all along the spike swelled considerably, and seemed to be full of the bud, and were consequently fertile, while all the others miscarried, and there was not one spike where the whole seeds did not ripen to the full.

This experiment is a sufficient proof of the use of the male flowers of this plant; for whatsoever that is which flows from the raceme of these flowers, it seems it must be conducive not only for the impregnation of the seed, but also for the growth and impregnation of the fruit.

At present we shall shew, that what nourishment is usually furnished by the pedicle to the embryos, does not appear to be capable to dilate or expand itself, or contribute to the continual supply of nutritious particles, unless the embryos were animated or enlivened by the spirit which should have flowed from the male flowers; so that they were so debilitated and weakened, in ascending from the body of the plant towards the embryos, before they could arrive at them, that they which otherwise might have served for the augmentation and increase of all the embryos upon the spike, could not now do any thing more than contribute to the ripening of a few. And although Mr. Geoffroy might have imagined, that these few seeds which came to perfection were fertile also, because they were full of germs, yet he could not be sure of that, unless he had sown the same seeds next season, and tried whether they would chit or not.

Gardeners who buy *Onion* and *Leek-seed* brought from *Strasburgh*, commonly try the following experiment: they put a few of the seeds into a pot of water mixed with earth, and if they find they begin to spring, or send forth the seminal leaf or fibre of the root, after a few days, they judge of the product of it; and notwithstanding all the seeds without this trial may seem to be productive, being equally firm, hard, and solid, perhaps not more than one third of them will prove fertile.

And this barrenness may proceed, either because they had never been impregnated by the male parts of the flower, or that they had been too much exposed to the air; being some time or other too much moistened, and not afterwards been carefully dried, or have been kept too long, by which neglect they lose their spirit or life.

Now, if the fulness, solidity and firmness of a seed is not a sure sign of its fertility, then Mr. Geoffroy might have been mistaken in his opinion of the fertility of these seeds in the *Maiz*, since he did not make any trial of it, by committing it to the ground.

In like manner, as to his second experiment of the *Mercurialis Dioscoridis*, where he raised some plants which had the fruit, and others which had the staminate flowers, and removed the floriferous plants before the flowers were blown, every one of the seeds upon the fructiferous plants, except five or six, miscarried; which seeds were so full, that he was persuaded they were capable of producing new plants, and the like was found by *Camerarius* in the *Cannabis*. Yet inasmuch as neither of them tried the experiment, by sowing the same seed the second year, they could not be sure but that they might have failed in their expectation.

Mr. Bobart, overseer of the physic-garden at Oxford, many years since, which was before the doctrine of the different sexes of plants was well understood, being herbarizing, found a plant of the *Lychnis sylvestris simplex*,

simplex, no apices; and taking notice that this was not only in one, but in all the flowers upon the same plant, he imagined it might be a new species; and therefore marked the plant, and took care to have it preserved till the seeds were ripe; and then, they being full, hard, and firm, and to outward appearance full of germ, he sowed them in a proper place in the garden the next season, but not a plant sprung up from them. These and other instances, set the opinion of the different sexes of plants upon another footing than has been received by most of our modern authors; for it imports, that it is not the nourishment of the gross substance of the seed itself which is hereby meant, nor the increase of the seed-vessel, which is thereby designed; for (as is already observed) a hen can lay an egg, without having before had congress with a cock; and this, when newly laid, shall be of the same bigness, colour, taste, and smell, with another egg which has been cocked (as they call it;) i. e. which has been fecundated by the masculine seminal materies: but the difference will appear, when both are put under the hen, in order to be hatched; for the one shall pululate or chit, and the other shall become fetid and rot.

The case is just the same with the seed of a plant, it may be augmented and increased in its bulk; it may become firm, hard, and solid, and have all the tokens of a perfect ripeness; the seed-vessels may be enlarged, and the pulp or parenchyma of the fruit may be augmented; and yet the particles of the seed may remain crude, indigested, and incapable to be explicated and dilated, or set in a suitable motion, whereby to protrude the fibrilla of the root at one end, and the seminal leaves at the other; except it has before received some extraneous matter, or some active particles from the male parts of the flower, or from the male flower itself.

In order to confirm the necessity of two sexes of plants, as well as in animals, this familiar consideration may be added: that the fertility or barrenness of any tree, in the more or less fruitful seasons, may be known to ignorant or less curious persons, by the quantity of the flowers which appear in the spring time; and that not only in trees alone, where the flower and fruit are upon one and the same foot-stalk, but also in such trees, where the flowers are upon distinct trees, or separate places upon the same tree; for it is easy to determine by the catkins or *ipili* upon the Walnut, Filbert, or Hazle-trees, whether such or such trees will be fertile or barren for the ensuing season, before any of the embryos begin to break, be pushed forth, or appear.

Having already treated of the male and female parts of flowers, we shall next consider their use.

Flowers, in this respect, may aptly be divided into that of male flowers, which (as has been before observed) were formerly reputed barren; and the plants which produce them were also called female plants, because those persons not having any notion of different sexes in plants, they were called female, upon account of their weakness; or if they had any thought of sexes in them, it was only illusive.

The ancients were ignorant of those which are now-a-days called hermaphrodite flowers; and they, not having a true notion of sexes of plants, could not imagine that the parts of both sexes should be in one flower, upon one and the same foot-stalk.

And although hermaphrodite animals bear the least proportion in the animal kingdom, yet hermaphrodites have the greatest share in the vegetable, though they are not so numerous as they have been supposed to be; for upon a strict examination it will be found, that a great many more plants have distinct male and female flowers, than was formerly believed.

The necessity of different sexes in plants having been demonstrated, and that the female seed, though it should ripen to the full, cannot be fertile, except it be impregnated by what it receives from the male parts of flowers, we shall next explain the organs of generation in both sexes.

In the animal œconomy, there are, besides those vessels that are destinated for nutrition, and the secretion of the several juices in the body, spermatic vessels, which consist of præparantia, deferentia, and continentia semen. The præparantia in males, are the blood-vessels and the testes; the one conveys the blood, and the other separates the semen from blood, and elaborates it.

So likewise in plants there are vessels that receive the nutritious particles from the earth, and convey it to the extremity of the plant; some of which tend directly to the leaf, and others to the flowers.

Those which go to the foot-stalk of the flower may not improperly be called spermatic-vessels, for it is from them that the seminal particles in male, female, and hermaphrodite flowers are separated; therefore the foot-stalks of the hermaphrodite flowers are proportionably larger than those either of the male or female; they have a double office, and contribute successively to both.

In those where the calyx becomes the fruit, the greatest supply is furnished to it first, and distributed in its cortical parts, as is visible in the Rose; in which the foot-stalk is so far enlarged at first, as to be of an equal bigness with the bud.

After the calyx is thus formed, the next distribution is to the inner or central part of the flower, which Dr. Grew calls attire, and where the pistillum becomes the fruit; the pistillum and stylus are formed at the same time with the stamina and apices.

The stylus at the very first acquires both its due length and bigness; for the nutritious particles ascending in the center never stop till the stylus is stretched out to its full length; and in such as are furnished with a peculiar apex, that is formed first; the neck of the stylus, or that part next to it, is the biggest; from thence it gradually decreases in its grossness, till it comes to the pistillum. This is easily perceived by those who will take the pains to open the bud of a Lily, Tulip, &c. before they are half blown.

The stamen is furnished next with an extraordinary supply of the nutritious particles before the flower is blown; these, whether fewer or more, are at first brought to their proportional largeness, being round and juicy.

The apex is the third which receives this extraordinary supply of the nourishment, for after that the stylus is formed, that it may lean to it after the vessels of the stamen and summit are extended to their full length, and so formed, that they can convey such an extraordinary quantity of particles as may fill up the capacity of the apex, it is then more enlarged than ever after; for if the flower of a Lily be opened before it be blown, the apex will be found to be full as long as the stamen; for as the one half of the apex covers the stamen, fixed to its center, so the other half of it is so far extended above the stamen, as the stamen remained uncovered below it, towards the pedicle or foot-stalk.

The fourth part of a flower is the petala, which receives this extraordinary supply of nourishment before the blowing; these upon the reverse, are first enlarged towards the pedicle, and are afterwards extended and stretched forth in proportion to the enlargement of the attire; at first they are all grosser, and more succulent towards the origin, and gradually become thinner and broader. The stamina of monopetalous flowers do, for the most part, arise partly from the petalon itself, and partly from the calyx; especially if the stamina correspond in number to the petala, as in the Hexapetalæ, or Polypetalæ Liliaceæ of Tournefort, where every stamen arises opposite to the middle of the petalon.

This observation (how and when this more than ordinary supply of nourishment is carried to the flowers) easily demonstrates wherein the analogy of the organs of generation in plants and animals consists.

In animals, the seminal matter is received by proper vessels from the same blood from whence the other secretions, fit for the preservation of the animal œconomy

mony proceed; so that the blood in animals being the same with the sap in plants, and both being conveyed after the same manner throughout the several bodies, it necessarily follows, that the one as well as the other, must have proper vessels for secretion of the seminal matter.

Let it then be considered, that the sap or nutritious juice ascends in common to the pedicle of the flower, as the blood flows by the aorta descendens; and that at the calyx or bottom of the flower, some share goes to one part of it, and some to another; as the aorta sends one branch to the spermatie vessels, and the remainder of it goes to perform the other functions; and as a part of the sap is separated by the pedicle of the flower, when the remainder is distributed throughout the remaining parts of the plant, so the arteria præparans goes directly to the testes in the males, and ovarium in the female: and in flowers some vessels tend directly to the calyx (if it becomes the fruit) or to the perianthium (if there be any,) some to the petala, some to the stamina, some to the pistillum or uterus, as it is called by Malpighius.

These things being seriously reflected on, we must of necessity conclude,

1. That the same due care is taken to elaborate and prepare the more subtile and impenetrable particles of the nutritious juice in plants, as of the blood in animals.

2. This substance so prepared, as it must be designed for some extraordinary use, so this use can be no other than that of being the means of fecundating the female seed in plants, as the other is of the feminine oval in animals.

If any one shall take a flower full blown, and pull one of the stamina from the pedicle, he will find a rough viscid liquor, like to the sperma, which remains here till its most subtile parts have ascended the stamina, or perhaps the more gross particles might have remained there, after the most subtile had ascended, before the flower was blown; this is as plain and demonstrable as can be in the Lilies, particularly in the Orange Lily, and most of the Martagon Lilies, there is a contrivance more obvious.

This viscid liquor ascending by parallel ducts to the apex, there this subtile matter is retained till it is farther elaborated by the evaporations of the more humid and aqueous particles, by the heat of the sun; and then it becomes a most subtile, fine, impalpable dust, which is then said to be ripe, and is called the farina.

Dr. Blair, after having given the sentiments of seven different authors upon the subject, proceeds to give his own, without subscribing to the sentiment of either the one or the other; and endeavours by a strict examination of the flowers themselves, to find out which of these two opinions, so diametrically opposite to each other, are most agreeable to fact.

But before he begins, he lays down this general maxim, which he takes for granted, that nature is uniform in all her operations, and never recedes from those rules laid down by the wise Disposer of all things at the creation, by performing the same thing after two different and contrary methods; and thence concludes, that if the farina be a congeries of seminal plants in one species, it must be so in all.

If there be an open and direct passage, or though it be not so direct, yet if by any direct passage, by which it can be demonstrated, that one single grain of the farina can enter every individual seed in one plant, it must be so in all; but if neither of these hold good, and if it can be proved by ocular inspection, without the assistance of a microscope, in those very plants exemplified by Mr. Morland, Mr. Geoffroy, and Mr. Bradley, that the farina in substance cannot enter the seminal vessel; or if it does, that there is no direct passage for it to enter each particular seed, after it has so got into the capsula or siliqua; then he hopes, both their queries, suppositions, and assertions, must fall.

As for the Corona Imperialis, the first example given

by Mr. Morland, the flower of which hangs downwards, though he does not deny but its stylus may be hollow all the way, and that it may be open at the extremity, yet by its situation, and several other circumstances, it does not seem to him to favour this opinion.

For first, as there is a continual conflux of particles through the skin in animal bodies, it is also so in vegetables: this appears by the immediate fading of flowers, or any other part of the plant, after it has been plucked off; which proceeds from the evaporation of the particles in the little tubes, without any more succeeding in their place.

He thinks it as reasonable to suppose, that these particles flow out by the hollow stylus, as by any other part, and also more sensibly there than elsewhere, because of their being concentrated within such narrow bounds; and that if these particles descend by the stylus hanging downwards, the particles, or rather grains of the farina, can never ascend the same way.

2dly, That if it should be granted, that these grains did ascend by the stylus, how do they get into the seminal vessel; that being closely shut up, as will appear to any one who shall observe it.

3dly, Whereas Mr. Morland supposes, that the rain either washes it, or the wind shakes it down the tube, till it reaches the seminal vessel; Dr. Blair observes, that the extremity which is the upper part of the stylus in an erect flower, must be the lower in a dependent one; so that if either the rain or wind have access to it, it must necessarily either wash or drive it away from the seminal vessel, which is now the stylus.

But here the Doctor takes notice of another contrivance, for answering that purpose, i. e. a sort of a pelvis or cistern, called by Linnæus nectarium, situated at the origin or root of each petalon, filled with a viscous liquor which continues there, and never exceeds its bounds so long as the petalon is in health: for since the apices are here so artfully fixed, that they turn every way with the least wind, as Mr. Morland rightly observes, when they burst, and the farina is driven to and fro, though it cannot so easily enter the tube, yet it may conveniently be blown up towards the orifice of the petala surrounding the stylus, where it is stopped or staid by this viscosity, till it has performed its office.

To confirm this, he instances Mr. Fairchild, who, he says, being persuaded that this viscous liquor did some way or other contribute towards the fructifying of this plant, but not understanding how it did so, he tried the experiment, by wiping this liquor off as soon as it was deposited in the pelvis, and the flower which he so served did not bear any fruit.

And the way the doctor accounts for this is, that the humidity being removed, the farina is no sooner blown upwards, than it immediately falls down, without producing any effect; and that which he takes to be a confirmation of this is, that both Tulips and Fritillarias have this pelvis or basin, yet it is for the most part dry and empty; because the flowers of the former being erect, they have no such need of this liquor to retain the dust; for that the rain, having immediate access to them, may wash the dust towards the origin of the petala, where it can remain till it has performed its office; whereas the rain having no access to the inner surface of the flower of the Corona Imperialis, it is naturally endowed with this humidity, deposited there by several excretory ducts, in order to render it fit for the purpose: and Malpighius himself takes notice of this singularity in this flower, though he ascribes no use to it.

The next example proposed by Mr. Morland, is the Yellow Lily, which, according to his figure, is represented as having the apices equally high with the top of the stylus, and the petala over-topping each other; whereas he says, that by the narrowest inspection he ever could make, the top of the apices (they being then perpendicularly situated) reaches no higher than the neck of the button upon the top of the stylus, and that this is before the apices begin to burst and

shed the dust; but as soon as the flower begins to open, they depart from the stylus, and force the petala outwards, by a certain elasticity, and expand themselves; this being done, they immediately change their posture from a perpendicular to an oblique or horizontal one; nor do they ever pour out their dust or farina, till they can conveniently drop it upon the bottom of the flower, and towards the root of the pistillum.

But taking it for granted that it was so, the top of the stylus (which the Doctor calls the button, in opposition to the apices staminum,) he says, is so compact, and of so firm a substance, that it is next to impossible, that the farina in substance, or in integral parts, can pass through it.

If the integral parts, the complete grain, the minute globuli, in which the whole seminal plant is contained, cannot then enter, the whole compound must be dissolved, and the minute seminal particles in this small grain of dust must be disunited; and if so, how shall these again come to cement, so as to make up one continued body? or how shall this little body, so united, penetrate a second time the partition-wall betwixt the stylus and pistillum? and again, how shall it find out its way to its nest, in the proper embryo of the seed?

The Doctor takes notice of the White Lily, the Orange Lily, the Martagon Lily, &c. as objections to the opinions of Mr. Morland, Bradley, &c. and also mentions the Iris, as a most pregnant instance, that the farina cannot so much as come at the pistillum; for having six petals, the three stamina with long apices lie hid between the three petala which hang downwards, and three large expansions of the bifid stylus, and the upper part of the down-hanging petalon: the farina can never reach the center of the stylus, though it were hollow, which it is not, but must descend along its outside, to the top and outside of the rudiment of the fruit, there to emit its effluvia. These and other instances he concludes, are sufficient proof, that the farina cannot enter the stylus, penetrate into the pistillum, or inner part of the seminal vessel, nor have the least access to the embryo of the seed.

As to the objection, that there is not passage sufficient to admit the male seed into the uterus, or even into the ovaries, it is thus answered:

If it be considered how every flower, when it is prepared for the act of receiving the male seed, is so much under the influence of the sun, that the petals open at its approach, and shut up again at its departure, it very well explains how the pistillum, or female parts of generation, are relaxed at one time more than another, i. e. that the female parts are more relaxed at the opening of the flower, than when the flower is shut up; for the flower-leaves adhering to the bottom of the pistillum, must consequently, when they bend back, put every part of the pistillum into a different posture to that in which it was when the petals were shut.

And it is certain, that it is the presence of the sun that ripens the male dust in the apices, and opens the little cases in which it is contained, giving them a springiness that flings forth that dust as soon as it is ripe, so as to scatter it to a considerable distance. The female parts are at this time dilated by the opening of the flower-leaves, and the apices and chives, concurring at the same time in flinging forth their male dust, answer the same end in the generation of plants, that the act of copulation does among animals.

Having thus given several reasonings and arguments used by various authors, who have made it their study to investigate the mode of generation of vegetables, whether the impregnation of them proceeds from the farina fecundans, or male dust, entering the uterus of plants in substances, or by effluvia, I shall not take upon me to determine the dispute; especially since Mr. Boyle has proved, that all effluvia are subtile particles of matter; so that it matters not how small or minute these particles are, since a body in its first state may be so minute as to be scarcely perceptible.

I shall therefore conclude with mentioning a few ex-

periments of my own, which I communicated to Dr. Patrick Blair, which he improved as a proof of his opinion of effluvia; and Mr. Bradley also, as a proof of the farina entering the uterus in substance, and leave the curious enquirer to determine on that side of the question, to which reasoning and experiment shall influence him.

I separated the male plants of a bed of Spinach from the female; and the consequence was, that the seed did swell to the usual bigness, but when sown it did not grow afterwards; and searching into the seed, I found it wanted the punctum vitæ, or what Geoffroy calls the germen.

I set twelve Tulips by themselves, about six or seven yards from any other, and as soon as they blew, I took out the stamina with their summits so very carefully, that I scattered none of the male dust; and about two days afterwards I saw bees working on a bed of Tulips, where I did not take out the stamina; and when they came out, they were loaded with the farina or male dust on their bodies and legs; and I saw them fly into the Tulips, where I had taken out the stamina, and when they came out, I found they had left behind them sufficient to impregnate the flowers, for they bore good ripe seeds which afterward grew.

In a parcel of Savoy, which were planted for seed near white and red Cabbages, the seeds, when sown, produced half red, and some white Cabbages, and some Savoy with red ribs, and some neither one sort nor the other, but a mixture of all sorts together in one plant, which I suppose might happen by the effluvia of the different sorts impregnating the uterus of each other.

In a letter communicated by Paul Dudley, Esq; to the Royal Society, written from New England, he mentions the interchanging of the colours of the Indian Wheat, if the various colours are planted in rows near each other; but if they are planted separately, they constantly keep to their own colour; and this interchanging of colours has been observed, when the distance between the rows of Corn has been several yards, though he says, if there happens to be a high board fence between the different coloured Corns, the alteration of colours is entirely prevented.

It is from different flowers impregnating each other, that the several varieties have been produced; and this gives new light to the florists, for raising a much greater variety of flowers; for by planting the different coloured flowers near each other, so that the flowers when fully blown may be intermixed, their farina will impregnate each other, so that the seeds will produce variegated flowers partaking of both colours. But it must be observed, that flowers of different genera will not impregnate each other, therefore the plants must be of the same genus which are placed together.

Cucumbers and Melons always produce male and female flowers upon different parts of the same plant; the male flower (which appears upon a slender foot-stalk, and has a large style in the middle, covered with an Orange-coloured farina) is by the gardeners commonly called false blossoms, and are sometimes by unskilful persons pulled off soon after they appear, supposing that they weaken the plants, if suffered to remain, which is a very great mistake; for, in order to try this experiment, I planted four holes of Melons in a place pretty far distant from any other; and when the flowers began to appear, I constantly pulled off all the male flowers from time to time before they opened; the consequence was, that all the young fruit dropt off soon after they appeared, and not one single fruit remained to grow to any size, though the vines were equally strong with those which I had planted in another place, where I suffered all the flowers to remain upon them, from which I had a great quantity of fruit. But this doctrine is now so well established among the gardeners, being confirmed by experience, that they now carry the male flowers of the Cucumbers and Melons to the female, if there are none situated

situated very near them, and gently strike the farina of the male, into the bosom of the female flowers, and thereby set the young fruit, which would otherwise drop off.

There are some persons, who still object to this theory of the generation of plants, from having observed some plants, which were termed female, growing singly, and at a very great distance from any male plants of the same kind, which had for some years produced seeds which were perfect, and grew when sown; and indeed I was myself a little staggered in my opinion, on having observed a female plant of the white Briony, which grew singly in a garden, where there were no other plants of the same kind; which for several years produced berries, which grew and flourished perfectly well. This put me upon examining the plant more carefully than I had before done, when I found there were great numbers of male flowers intermixed with the female, on the same plant; and since then I have frequently found the same in many other plants, which are sometimes male and female in different plants, yet have sometimes both sexes on the same plant; so that the objections which have been made to this doctrine, may not have proper evidence for their support.

It is certain, that the female plants may produce fruit, without the impregnation of the male; but it is not certain, that this fruit or seed will, if sown, produce another plant. What has been so often related by travellers and historians, of the necessity of the male Palm-tree being near the female, in order to render it fruitful, hath been fully confirmed by Father Labat, in his account of Africa, where he has treated of the several sorts of Palms: he says, that he observed in Martinico a large Palm-tree, which grew by the side of a convent, which produced plenty of fruit, though there was no other Palm-tree growing within two leagues of this; but he also observed, that none of these fruit would grow, though they had made many trials of them; so that they were obliged to procure some fruit from Barbary, in order to propagate these trees. He likewise adds, that the fruit which grew on this female tree, never ripened so perfectly, nor was so well tasted, as those which came from trees which had stood near some of the male: therefore we may conclude, that the fruit or seed may be produced by the female plants of most kinds, without the assistance of the male sperm, which may appear to fight perfect, and fit to produce others; but if we examine the seeds, we shall find that most of them have not the germ or little plant inclosed, nor will grow if they are sown.

From these and many other experiments, it is very plain, that there is a necessity that the embryo of the female flower should be impregnated by the farina or male dust, in order to render the fruit perfect; but how, or in what manner it is performed, is what we can only guess at, since in the generation of animals, our greatest naturalists differ very much in their opinions; nor can any of them ascertain any particular method how it is performed. I shall therefore conclude with quoting the words of the Rev. Dr. Hales, which are a most ingenious summary of the whole doctrine of the generation of plants.

"If I (says he) may be allowed to indulge conjecture in a case in which the most diligent enquirers are, as yet, after all their laudable researches, advanced but little farther than mere conjecture, I would propose it to their consideration, whether from the manifest proof we have, that sulphur strongly attracts air, a hint may not be taken, to consider whether this may not be the primary use of the farina fecundans, to attract or unite with elastic or other refined active particles. That this farina abounds with sulphur, and that a very refined sort, is probable from the subtle oil which chymists obtain from the chives of Saffron; and if this be the use of it, was it possible that it could be more aptly placed for the purpose on very moveable apices

"fixed on the slender points of the stamina, whereby it might easily, with the least breath of wind, be dispersed in the air, thereby surrounding the plant, as it were, with an atmosphere of sublimed sulphureous pounce? for many trees and plants abound with it, which uniting with the air particles, may, perhaps, be inspired at several parts of the plant, and especially at the pistillum, and be thence conveyed to the capsula seminalis, especially towards evening, and in the night, when the beautiful petals of the flowers are closed up, and they, with all the other parts of the vegetable, are in a strongly imbibing state. And if to these united, sulphureous and aerial particles, we suppose some particles of light to be joined (for Sir Isaac Newton has found, that sulphur attracts light strongly;) then the result of these three by far the most active principles in nature, will be a punctum saliens to invigorate the seminal plant; and thus we are at last conducted, by the regular analysis of vegetable nature, to the first enlivening principle of their minutest origin."

GENISTA A. Lin. Gen. Plant. 766. Tourn. Inst. R. H. 643. tab. 412. Broom; in French, *Genêt*.

The CHARACTERS are,

The empalement of the flower is of one leaf, tubulous, and divided into two lips; the upper lip is deeply cut into two, and the under into three equal parts. The flower is of the butterfly kind; the standard is oval, acute, and remote from the keel, being wholly reflexed; the wings are a little shorter than the standard, and are loose: the keel is erect, and longer than the standard, and is indented at the top. It hath ten stamina joined in two bodies, which are situated in the keel, terminated by single summits. In the center is an oblong germen, supporting an ascending style, crowned by an acute twisted stigma. The germen afterward becomes a roundish turgid pod with one cell, opening with two valves, inclosing kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes the plants with flowers having ten stamina, joined in two bodies; and to this he adds some of Tournefort's species of Spartium, and the Genistella of Tournefort.

The SPECIES are,

1. GENISTA (*Sagittalis*) ramis ancipitibus articulatis, foliis ovato-lanceolatis. Hort. Cliff. 355. *Jointed Broom, with two-edged branches, and jointed, oval, spear-shaped leaves.* Chamæ Genista sagittalis. C. B. P. 395. *Dwarf arrow-shaped Broom.*
2. GENISTA (*Florida*) foliis lanceolatis, ramis striatis teretibus racemis secundis. Hort. Cliff. 355. *Broom with spear-shaped leaves, and erect taper branches abounding with flowers.* Genista tinctoria Hispanica. C. B. P. 395. *Spanish Dyers Broom.*
3. GENISTA (*Tinctoria*) foliis lanceolatis glabris ramis striatis teretibus erectis. Hort. Cliff. 355. *Broom with spear-shaped leaves which are acute, and taper channelled branches proceeding from the side of the stalk.* Genista tinctoria Germanica. C. B. P. 395. *Common Dyers Broom, or Wood-waxen.*
4. GENISTA (*Purgans*) spinis terminalibus, ramis teretibus striatis, foliis lanceolatis simplicibus pubescentibus. Lin. Sp. 999. *Broom with taper-streaked branches terminated by spines, and simple, spear-shaped, hairy leaves.* Genista sive spartium purgans. J. B. I. p. 404.
5. GENISTA (*Candicans*) foliis ternatis subtus villosis, pedunculis lateralibus subquinquefloris foliatis, leguminibus hirsutis. Amœn. Acad. 4. p. 284. *Trifoliate Broom with hairy leaves, foot-stalks from the side of the branches having five flowers, and hairy pods.* Cytisus Monspesulanus, medicæ folio, siliquis dense congestis & villosis. Tourn. Inst. 648.
6. GENISTA (*Tridentata*) ramis triquetris subarticulatis, foliis tricuspidatis. Lin. Sp. Plant. 710. *Broom with three-cornered jointed branches, and leaves ending in three points.* Genistella fruticosa Lusitanica. Tourn. Inst. 646. *Shrubby Portugal Dyers Broom.*
7. GENISTA (*Pilosa*) foliis lanceolatis obtusis, caule tuberculato decumbente. Hort. Cliff. 355. *Broom with obtuse*

obtusely spear-shaped leaves, and a declining stalk having tubercles. This is the *Genista ramosa*, foliis Hyperici. C. B. P. 395. *Branching Broom with leaves like St. Johnswort.*

8. *GENISTA (Anglica)* spinis simplicibus, ramis floriferis inermibus, foliis lanceolatis. Hort. Cliff. 355. *Broom with single spines, flower-branches without spines, and spear-shaped leaves.* *Genista spartium minus Anglicum.* Tourn. Inst. R. H. 645. *Small English Broom, called Petty Whin.*

9. *GENISTA (Hispanica)* spinis decompositis, ramis floriferis, inermibus, foliis lanceolatis. Lin. Sp. Plant. 711. *Broom with decomposed spines, flower-branches without spines, and narrow hairy leaves.* *Genista spinosa minor Hispanica villosissima.* C. B. P. 395. *Most hairy, small, Spanish, prickly Broom.*

The first sort grows naturally in France, Italy, and Germany. This plant sends out several stalks from the root, which spread flat on the ground, and divide into many flat branches which are jointed, and their two sides are edged like a broad sword; these are green and herbaceous, but are perennial. At each of the joints is placed one small spear-shaped leaf, without any foot-stalk. The flowers are produced in close spikes at the end of the branches; they are yellow, and of the Pea-bloom kind, and are succeeded by short hairy pods, which contain three or four kidney-shaped seeds. The plants flower in June, and the seeds ripen in September.

This sort is propagated by seeds, which, if sown in the autumn, the plants will come up the following spring; but when they are sown in the spring, the plants rarely come up the same year: when the plants come up, they will require no other culture but to keep them clean from weeds, and thin them where they are too close; at Michaelmas they may be transplanted where they are designed to remain, and after that they will only require to be kept clean, for they are very hardy, and will live several years.

The second sort rises with ligneous stalks about two or three feet high, sending out many taper channelled branches which grow erect, garnished with small spear-shaped leaves placed alternate, and are terminated by several spikes of yellow flowers, which are of the Pea-bloom kind; these are succeeded by short pods, which turn black when ripe, and contain four or five kidney-shaped seeds. It flowers in June and July, and the seeds ripen in autumn.

The third sort grows naturally in England. This hath shrubby stalks, which rise about three feet high, garnished with spear-shaped leaves, which are broader, and end in sharper points than those of the former; the branches come out from the side of the stalks, almost their whole length, and do not grow so upright as those of the second; these are terminated by loose spikes of yellow flowers, which are succeeded by pods like those of the second sort. It flowers, and the seeds are ripe about the same time as the former. The branches of the plant are used by the dyers, to give a yellow colour, from whence it is called Dyers Broom, Green-wood, Wood-waxen, or Dyers-weed.

The fourth sort grows naturally about Montpellier. This rises with shrubby, striated, taper stalks four feet high, sending out several branches which are terminated by spines; the leaves are spear-shaped, single, and hairy; the flowers are produced in spikes at the end of the branches, they are larger than those of the other sorts, and are of a paler yellow colour. They appear in June and July, and are succeeded by pods like the former sorts.

This sort is tender, and in severe frosts is often killed in England, where the plants are not protected.

The fifth sort grows naturally about Montpellier. This rises with a woody stalk to the height of seven or eight feet, sending out many slender branches, garnished with trifoliate leaves, hairy on their under side; the upper part of these branches, for more than a foot in length, send out small flowering branches on their side, supporting five yellow flowers. These

appear in June and July, and the seeds ripen in autumn.

The sixth sort hath a low shrubby stalk, which seldom is more than a foot high, sending out several weak branches which are jointed, garnished with small leaves ending in three acute parts. The flowers are produced in loose spikes at the top of the branches, they are of a pale yellow colour, and appear the latter end of June and in July, and the seeds ripen in September. This plant grows naturally in Portugal.

The seventh sort hath a shrubby stalk which declines toward the ground, and is set over with tubercles; it divides into a few small branches, which are garnished with small obtuse leaves. The flowers are disposed in small loose spikes at the end of the branches; they are small, of a pale yellow colour, and are succeeded by short pods filled with kidney-shaped seeds. It flowers in June, and the seeds ripen in autumn. This grows naturally in Germany and France.

The eighth sort grows naturally upon open heaths in many parts of England. It hath a shrubby stalk which rises about two feet high, sending out many slender branches, which are armed with long single spines, and garnished with very small spear-shaped leaves, placed alternate on every side the branches: the flower-branches have no spines; these are short, and have five or six yellow flowers growing in a cluster at the end. They come out in April and May, and are succeeded by short turgid pods, which contain four or five small kidney-shaped seeds. These ripen in July.

The ninth sort grows naturally in Spain. This hath a low shrubby stalk, which sends out many ligneous branches, armed with branching thorns, composed of several sharp thorns, which come out from each other, but the short branches which produce the flowers have no spines; these are garnished with small hairy leaves of different forms, some of them being as narrow as hairs, and others are of the spear-shape; the branches are terminated by clusters of yellow flowers, which are succeeded by short, compressed, hairy pods, filled with kidney-shaped seeds. The whole plant has much the appearance of the common Furz or Gorse, but is very hairy, and the flower-branches being without thorns, are the most obvious distinctions.

All these sorts of Brooms are propagated by seeds, which, if sown in the autumn, will succeed much better than if sown in the spring, and a year will be thereby saved; as these plants send out long, stringy, tough roots, which run deep into the ground, they do not bear transplanting well, especially if they are not removed young; therefore the best way is to sow a few seeds in those places where the plants are designed to remain, and to pull up all except the most promising plants as soon as they are past danger; after this the plants will require no other culture, but to keep them clean from weeds: but where this cannot be practised, the seeds may be sown thin upon a bed of light earth, and when the plants come up, they must be kept clean from weeds till the following autumn, when the plants should be carefully taken up and transplanted where they are designed to remain. They are all very hardy plants except the fourth, fifth, and ninth sorts, which must have a warm sheltered situation and dry soil, otherwise they will not live through the winter, but the others will grow in almost any soil or situation.

GENISTA SPINOSA, the Furz, Whins, or Gorse. See ULEX.

GENTIANA. Lin. Gen. Plant. 285. Tourn. Inst. R. H. 80. tab. 40. [takes its name from Gentius, a king of Illyrium, who first discovered the virtues of this plant.] *Gentian*, or *Fellwort*; in French, *Gentiane*.

The CHARACTERS are,

It hath a permanent empalment, which is cut into five acute segments. The flower hath one petal, which is tubulous, cut into five parts at the top, which are flat. It
hath

both five awl-shaped stamina, which are shorter than the petal, terminated by single summits. In the center is situated an oblong cylindrical germen, having no style, but is crowned by two oval stigmas. The germen afterward becomes an oblong taper-pointed capsule, with one cell, containing many small seeds fastened to the valves of the capsule.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, which includes the plants whose flowers have five stamina and two stigmas.

The SPECIES are,

1. GENTIANA (*Lutea*) corollis quinquefidis rotatis verticillatis, calycibus spathaceis. Hall. Helv. 479. *Gentian with quinquefid wheel-shaped petals growing in whorls, and hood-like empalements.* Gentiana major lutea. C. B. P. 187. *Greater yellow Gentian.*
2. GENTIANA (*Pneumonanthe*) corollis quinquefidis campanulatis oppositis pedunculatis, foliis linearibus. Lin. Sp. Plant. 228. *Gentian with bell-shaped quinquefid petals placed opposite upon foot-stalks, and very narrow leaves.* Gentiana angustifolia autumnalis major. C. B. P. 188. *Greater narrow-leaved autumnal Gentian.*
3. GENTIANA (*Asclepiades*) corollis quinquefidis campanulatis oppositis sessilibus, foliis amplexicaulibus. Lin. Sp. Plant. 227. *Gentian with bell-shaped quinquefid petals sitting close to the stalk opposite, and leaves embracing the stalk.* Gentian Asclepiades folio. C. B. P. 187. *Gentian with a Swallow-wort leaf.*
4. GENTIANA (*Acaulis*) corollâ quinquefidâ campanulatâ, caulem excedente. Lin. Sp. Plant. 228. *Gentian with a bell-shaped quinquefid petal exceeding the stalk.* Gentiana Alpina latifolia, magno flore. C. B. P. 187. *Broad-leaved Alpine Gentian with a large flower, commonly called Gentianella.*
5. GENTIANA (*Nivalis*) corollis quinquefidis infundibuliformibus, ramis unifloris alternis. Lin. Sp. Plant. 229. *Gentian with funnel-shaped quinquefid petals, and alternate branches having one flower.* Gentiana annua, foliis Centaurii minoris. Tourn. Inst. 81. *Annual Gentian with lesser Centaury leaves.*
6. GENTIANA (*Cruciata*) corollis quadrifidis imberbibus verticillatis sessilibus. Lin. Sp. Plant. 231. *Gentian with quadrifid petals without beards, growing in whorls close to the stalks.* Gentiana cruciata. C. B. P. 188. *Crosswort Gentian.*
7. GENTIANA (*Ciliata*) corollis quadrifidis margine ciliatis. Lin. Sp. Plant. 231. *Gentian with a four-pointed petal, whose border is hairy.* Gentianella cærulea oris pilosis. C. B. P. 188. *Blue Gentian with hairy brims.*

Cat. 3. *Lesser maritime Centaury with a large blue flower.*

The first sort is the common Gentian of the shops,

whose root is one of the principal ingredients in bitters.

This plant has a large thick root of a yellowish brown colour, and a very bitter taste; the lower leaves are of an oblong oval shape, a little pointed at the end, stiff, of a yellowish green, and have five large veins on the back of each, and are plaited. The stalk rises to the height of three or four feet, which is garnished with leaves, growing by pairs at each joint, almost embracing the stalk at their base; these are of the same form with the lower, but diminish gradually in their size to the top. The flowers come out in whorls at the joints, toward the upper part of the stalks, standing on short foot-stalks, whose origin is from the wings of the leaves; these are of a pale yellow, and have one petal, which is divided almost to the bottom, having an oblong cylindrical germen, which afterward swells to an oblong taper capsule, which is bifid at the point, and opens in two cells, filled with small seeds.

It grows naturally in the pastures in Switzerland, and in the mountainous parts of Germany, from whence the roots are brought to England for medicinal use; there is a compound water, and an extract made of them. The root of the Gentian is also one of the principal ingredients in bitters, and is frequently used in many disorders.

But a few years ago, there was a mixture of Henbane roots brought over with Gentian, which was unhappily used, and occasioned great disorders in the persons to whom it was administered; upon which great enquiry was then made to find out what that root could be, some suspecting it to be the root of Deadly Nightshade, and others believing it to be some of the poisonous umbelliferous roots, but on comparing it with some dried roots of the Henbane, I found they were the same. We have likewise an account of the noxious quality of these roots, printed in the Synopsis Stirpium Hibernicarum, which was communicated to the author by Dr. Thomas Molyneux, physician to the state; it was as follows:

The Dean of Clonfert was making some alterations in his garden, and, looking over his workmen, he observed them to dig up many roots, which he took for Skirrets, and therefore ordered some of them to be carried in and dressed for dinner, which was accordingly done; but all those who eat of them were in a short time seized with dizziness in their head, sickness at the stomach, attended with an unusual heat and dryness in their throats; and two, who had eaten a larger share than the rest, lost the use of their reason, and became delirious, which continued for some days; and as it appeared evident these disorders were occasioned by the roots, the Dean caused some of them to be planted, that he might be assured what the plant was whose roots had this bad quality; and in the spring, when they put out their leaves, they proved to be the Henbane, which has been noticed by old writers to be possessed of these qualities. And as the disorders which were occasioned by these supposed Gentian roots, were nearly the same, as is above related, I thought it might be of use to insert it here, to caution others against eating of roots which they are unacquainted with.

This plant delights in a light loamy soil and a shady situation, where it will thrive much better than in a light dry soil, or in an open exposure. It is propagated by seeds, which should be sown in pots soon after it is ripe, for if it is kept till the spring, it will not succeed; these pots should be placed in a shady situation, and kept clean from weeds. In the spring the plants will appear, when they must be duly watered in dry weather, and kept clean from weeds till the following autumn; then they should be carefully shaken out of the pots, so as not to break or injure their roots; and a shady border of loamy earth should be well dug and prepared to receive them, into which the plants should be planted at about six inches distance each way, observing to let the top of the roots be a little below the surface of the

ground, then press the earth close to the roots; after this they will require no farther care, but to keep them constantly clean from weeds; and if the following spring should prove dry, they should be duly watered, which will greatly forward their growth. In this border the plants may stand two years, by which time they will be fit to transplant where they are designed to remain; therefore in autumn, so soon as their leaves decay, they may be removed; but as the roots of these plants run deep into the ground, like Carrots, there must be great care taken in digging them up, not to cut or break their roots, for that will greatly weaken, if it does not kill them. After the plants are well fixed in their places, they require no other culture, but to dig the ground about them early in the spring before they begin to shoot, and in the summer to keep them clean from weeds. The roots of these plants will continue many years, but the stalks decay every autumn; the same roots do not flower two years together, nor seldom oftener than every third year; but when they flower strong, they make a fine appearance; and as these delight in shady moist ground, where but few ornamental plants will thrive, so they should not be wanting in good gardens.

The second sort grows naturally in moist pastures in many parts of England, but particularly in the north; this rises with an upright stalk about a foot high, garnished with smooth leaves an inch and a half long, and less than a quarter of an inch broad; they are placed opposite, and have no foot-stalks. The flowers are produced on the top of the stalk, three or four in number, standing upon foot-stalks alternately above each other; they are large, bell-shaped, and divided into five points at their brim, and are of a deep blue colour, so make a fine appearance; these come out the latter end of July in the warm parts of England, but in the north they are full a month later.

It may be propagated by seeds in the same manner as the first sort, and the plants may be treated in the same way; but as this sort does not shoot its roots deep into the ground, it may be transplanted with less hazard; however, if these are removed with a ball of earth to their roots, they will not feel their removal so much as when the earth is all taken from them. This sort should be planted in a strong, moist, loamy soil, in which the plants will thrive and flower annually, but in a warm dry soil they will not thrive or flower.

The third sort grows naturally upon the Helvetian mountains; this rises with an upright stalk near a foot high, garnished with smooth leaves about two inches long, and three quarters of an inch broad at their base, where they embrace the stalk, but they end in acute points; they are placed opposite, and are of a fine green, and diminish in their size as they are nearer the top; they have five longitudinal veins, which join at both ends, but diverge from each other in the middle. The flowers come out by pairs opposite, from the bottoms of the leaves, standing on short foot-stalks; they are pretty large, bell-shaped, and of a fine blue colour, so make a fine appearance when they are open. This sort flowers in June and July.

It may be propagated by seeds in the same manner as the first sort, and the plants may be treated in the same way, but they must have a moist loamy soil, otherwise they will not thrive. It may also be propagated by offsets, which may be divided from the roots; these should be taken off in autumn, which is the best season for removing all these sorts of plants; but these should not be removed, or parted oftener than every third year, where they are expected to produce strong flowers.

The fourth sort grows naturally on the Alps and Helvetian mountains, but has been long cultivated in most of the curious gardens in Europe; this is commonly known by the title of *Gentianella*. It is a low plant, the stalks seldom growing more than three or

four inches high; they are garnished with smooth leaves placed opposite, which are two inches long, and half an inch broad, sitting close to the stalk. The flowers grow erect on the top of the stalk, so stand quite above them; these are often single, but sometimes, when the plants are strong, there will be four or five at the end of each stalk; they are large, bell-shaped, and of a deep azure blue, so is the finest of that colour of any flower yet known. It usually flowers in May, but sometimes the plants flower again in autumn.

This is commonly propagated by parting of the roots, in the same manner as is before directed for the third sort, but these must not be often transplanted, or parted, if they are wanted to flower strong; this sort should have a soft loamy soil and a shady situation, where the plants will thrive and flower well every year.

It may also be propagated by seeds, which, in a good soil, the plants will produce in plenty; these should be sown in autumn, in the same manner as is before directed for the first sort; and if the plants are planted in a good soil, they will be strong enough to flower the second year after they come up, and these seedling plants will flower much stronger than those which are propagated by offsets.

The fifth and eighth sorts are low annual plants, which grow naturally upon the Alps and other mountainous places in Europe, and are very rarely cultivated in gardens. The fifth seldom rises more than two inches high, branching out from the root into several slender stalks, garnished with very small leaves placed by pairs, and each stalk is terminated by one smaller blue flower standing erect. The eighth sort grows about four inches high, with a single upright stalk of a purple colour. The leaves at the root are oval, but those upon the stalk are narrow, and stand opposite. The stalk is terminated by one blue flower, with a large bellied empalement, which is plaited, and the petal of the flower rises but a little above the empalement, so does not make much appearance. After the top flower decays, there are frequently two smaller flowers which come out from the side of the stalk, at the two upper joints; these flower after each other, the upper one coming first, so that there is a succession of flowers till autumn.

As these plants usually grow upon moist spongy ground, it is very difficult to cultivate them in gardens; for unless they have a soil approaching near to that in which they naturally grow, they will not thrive; the only method to obtain them is, either to sow their seeds in pots, or upon a moist boggy ground in autumn, but it must be in the shade; and when the plants come up, they may be thinned, and the surface of the ground about them covered with moss, which should be constantly kept moist; with this management I have seen the plants thrive and flower very well.

The sixth sort is a perennial plant, which grows naturally upon the Appenines and the Helvetian mountains; this rises with an upright stalk about six inches high, garnished with smooth spear-shaped leaves about two inches long, and one broad in the middle, sitting close to the stalk; they are placed opposite, and each pair of leaves cross one another, from whence it is called *Crosswort Gentian*. The flowers are produced in whorls round the stalks at the upper joints, sitting very close to the stalks, and at the top there is a large cluster growing in the same form; these are of a light blue colour, and appear in May. This may be propagated by seeds, or offsets, in the same manner as the third and fourth sorts, and the plants must be treated in the same way.

The seventh sort grows naturally upon the Alps, and other mountainous parts of Europe; this is a low perennial plant, whose stalks are very slender, and rarely rise more than three or four inches high, garnished with small, narrow, acute-pointed leaves, placed in pairs; each stalk is terminated by one large blue flower, which is hairy on the inside at the brim. This

flowers

flowers in July and August, and may be propagated and treated in the same manner as the third and fourth forts.

The ninth fort is the Lesser Centaury of the shops; this grows naturally upon dry pastures in most parts of England, where it rises in height proportionable to the goodness of the soil; for in good land it is frequently a foot high, but in poor soils not more than three or four inches. It is an annual plant, with upright branching stalks, garnished with small leaves placed by pairs. The flowers grow in form of an umbel at the top, and are of a bright purple colour; they come out in July, and the seeds ripen in autumn. This plant cannot be cultivated in the gardens.

The tenth fort grows naturally upon chalky grounds in many parts of England. It is an annual plant, rising with an upright stalk a foot high, garnished with oval-pointed leaves, whose base surrounds the stalk; they grow by pairs, and are of a gray colour; the stalks and leaves are very smooth. The flowers grow in form of an umbel on the top of the stalk; they are of a bright yellow colour, and are cut into eight parts at the top. These appear in July, and the seeds ripen in autumn.

The eleventh fort is an annual plant, which grows naturally in the south of France and in Italy; this rises with an upright stalk about a foot high, sending out several branches toward the top, which are garnished by small leaves placed opposite. The flowers are produced from the side and at the top of the stalk, in form of loose irregular umbels; they are white, and about the size of those of the common Centaury.

The twelfth fort grows naturally in the West-Indies, where it was discovered by Father Plumier, and the late Dr. Houstoun found it growing in plenty at La Vera Cruz, in low moist places where the water stagnates, but at a remoter distance from the sea. The seeds of this plant he sent to England, which succeeded in the Chelsea garden; this rises with an upright branching stalk near two feet high, garnished with oblong, smooth, acute-pointed leaves, placed opposite; the upper part of the stalk divides into several forks, between which are six or seven long naked foot-stalks, each sustaining one large blue flower, divided into five segments at the brim. The flowers are succeeded by oblong capsules with one cell, filled with small seeds.

This is propagated by seeds, which must be sown on a hot-bed soon after they are ripe, and the plants afterward treated in the same manner as other tender annual plants from warm countries, being too tender to thrive in the open air in England. If the seeds of this plant are sown in autumn, in pots placed in the tan-bed of the stove, they will succeed better than when they are sown in the spring, and the plants will flower early, so good seeds may be obtained.

GENTIANELLA. See GENTIANA.

GERANIUM. Lin. Gen. Plant. 346. Tourn. Inst. R. H. 266. tab. 142. [takes its name from *Γέρανος*, Gr. a crane, or stork, because its fruit resembles the bill of a Crane.] *Crane's-bill*; in French, *Bec de Grue*.

The CHARACTERS are,

The flower hath a permanent empalement, composed of five small oval leaves. The flower hath five petals, which are oval, or heart-shaped, spreading open; these are in some species equal, and in others, the upper two are much larger than the three lower. It hath ten stamina, which are alternately longer, but are shorter than the petals, and are terminated by oblong summits. In the bottom of the flower is situated a five-cornered germen, supporting an awl-shaped style longer than the stamina, which is permanent, crowned by five reflexed stigmas. The flower is succeeded by five seeds, each being wrapped up in the husk of the beak, which is extended the length of the style, where they are twisted together at the point, so as to form the resemblance of a stork's beak.

This genus of plants is ranged in the second section of Linnæus's sixteenth class, which includes those plants whose flowers have ten stamina, and the male and female organs are joined in one body. Tournefort

places it in the sixth section of his sixth class, in which he ranges the herbs with a Rose-flower, whose pointal becomes a fruit with several capsules.

The SPECIES are,

1. GERANIUM (*Pratense*) pedunculis bifloris, foliis subpeltatis multipartitis pinnato laciniatis rugosis acutis, petalis integris. Hort. Cliff. 344. *Crane's-bill with two flowers on each foot-stalk, target-shaped leaves cut into many acute segments, and entire petals.* Geranium batrachioides, Gratia Dei Germanorum. C. B. P. *Crane's-bill with a Crow-foot leaf, and large blue flowers.*
2. GERANIUM (*Macrorrhizum*) pedunculis bifloris, calycibus inflatis, pistillo longissimo. Hort. Cliff. 343. *Crane's-bill with two flowers on each foot-stalk, inflated empalements, and a very long pointal to the flower.* Geranium batrachioides, longius radicum, odoratum. J. B. *Long-rooted sweet-smelling Crane's-bill, with a Crow-foot leaf.*
3. GERANIUM (*Sanguineum*) pedunculis unifloris, foliis quinquepartitis trifidis orbiculatis. Lin. Sp. Plant. 685. *Crane's-bill with one flower on each foot-stalk, and orbicular leaves, which are trifid and divided into five parts.* Geranium sanguineum, maximo flore. H. Ox. *Bloody Crane's-bill with a larger flower.*
4. GERANIUM (*Lancastrense*) pedunculis unifloris, foliis quinquepartitis laciniis obtusis brevibus, caulibus decumbentibus. *Crane's-bill with one flower upon each foot-stalk, leaves divided into five parts, whose segments are short, blunt, and declining stalks.* Geranium hæmatodes Lancastrense, flore eleganter striato. Raii Hist. *Bloody Crane's-bill with a variegated flower.*
5. GERANIUM (*Nodosum*) pedunculis bifloris, foliis caulinis trilobis integris serratis, summis subsessilibus. Hort. Cliff. 343. *Crane's-bill with two flowers on each foot-stalk, the leaves upon the stalks having three entire sawed lobes, the upper leaves sitting close to the stalk.* Geranium 5. nodosum. Plateau. Clus. Hist. *Knotty Crane's-bill.*
6. GERANIUM (*Phæum*) pedunculis bifloris, foliisque alternis, calycibus subaristatis, caule erecto, petalis undulatis. Lin. Sp. Plant. 681. *Crane's-bill with two flowers on each foot-stalk, alternate leaves, bearded empalements, an erect stalk, and waved petals to the flower.* Geranium phæum sive fuscum, petalis reflexis, folio non maculoso. H. L. *Brown Crane's-bill with reflexed petals, and leaves not spotted.*
7. GERANIUM (*Fuscum*) pedunculis bifloris, foliis quinquelobatis incis, petalis reflexis. *Crane's-bill with two flowers upon each foot-stalk, leaves divided into five lobes, which are cut, and the petals of the flowers reflexed.* Geranium phæum sive fuscum, petalis rectis seu planis, folio maculato. H. L. *Brown Crane's-bill with plain petals, and spotted leaves.*
8. GERANIUM (*Striatum*) pedunculis bifloris, altero brevior, foliis quinquelobis medio dilatatis, petalis bilobis venoso reticulatis. Burm. Ger. *Crane's-bill with two flowers upon each foot-stalk, one bigger than the other, leaves having five lobes, and flowers with two lobes.* Geranium Romanum, versicolor sive striatum. Park. Par. *Roman Crane's-bill with striped flowers.*
9. GERANIUM (*Sylvaticum*) pedunculis bifloris, foliis subpeltatis quinquelobis inciso-serratis, caule erecto, petalis emarginatis. Flor. Lapp. 266. *Crane's-bill with two flowers on each foot-stalk, target-shaped leaves with five lobes deeply sawed, an erect stalk, and indented petals to the flower.* Geranium batrachioides montanum nostras. Ger. *Mountain Crane's-bill with a Crow-foot leaf.*
10. GERANIUM (*Orientale*) pedunculis bifloris, foliisque oppositis, petalis integris, calycibus brevioribus. *Eastern Dove's-foot Crane's-bill, with opposite leaves, two flowers on each foot-stalk, and a short empalement.* Geranium Orientale columbinum, flore maximo, asphodeli radice. T. Cor. *Oriental Dove's-foot Crane's-bill, with an Asphodel root and large flowers.*
11. GERANIUM (*Percenne*) pedunculis bifloris, foliis inferioribus quinque-partito-multifidis rotundis, superioribus trilobis, caule erecto. Hudf. Flor. Ang. 265. *Crane's-bill with two flowers on each foot-stalk, the lower leaves having five many-pointed lobes, the upper three,*

three, and an erect stalk. *Geranium Columbinum* perenne Pyrenaicum maximum. Tourn. Inst. R. H. 268. *Greatest perennial Dove's-foot Crane's-bill of the Pyrennes.*

12. GERANIUM (*Alpinum*) pedunculis longissimis multifloris, calycibus aristatis, foliis bipinnatis. *Crane's-bill with very long foot-stalks sustaining many flowers, bearded empalements, and double wing-pointed leaves.* *Geranium Alpinum Coriandri folio*, longius radicatum, flore majore purpureo. Michel. *Alpine Crane's-bill with a Coriander leaf, a long root, and a larger purple flower.*
13. GERANIUM (*Argenteum*) pedunculis bifloris, foliis subpeltatis septempartitis trifidis tomentoso-sericeis, petalis emarginatis. Amœn. Acad. 4. p. 324. *Crane's-bill with two flowers on each foot-stalk, target-shaped leaves divided into seven parts, which are silvery, and the petals of the flower indented.* *Geranium argenteum Alpinum.* C. B. P. 318. *Silvery Alpine Crane's-bill.*
14. GERANIUM (*Maculatum*) pedunculis bifloris, caule dichotomo erecto, foliis quinquepartitis incisissimis sessilibus. Flor. Virg. 78. *Crane's-bill with two flowers on each foot-stalk, upright stalks divided by pairs, and cut leaves divided into five parts, the upper sitting close to the stalk.* *Geranium batrachiodes Americanum maculatum*, floribus obsolete cæruleis. Hort. Elth. 158. *American spotted Crane's-bill with obsolete blue flowers.*
15. GERANIUM (*Bohemicum*) pedunculis bifloris petalis emarginatis arillis hirtis cotyledonibus trifidis medio truncatis. Burm. Ger. 4. *Crane's-bill with two flowers on each foot-stalk, indented petals to the flower, hairy beards, and a trifid leaf.* *Geranium annuum minus batrachiodes Bohemicum*, purpureo-violaceum. Mor. Hist. 2. 511. *Lesser annual Crane's-bill of Bohemia, with a purple Violet flower.*
16. GERANIUM (*Sibiricum*) pedunculis subunifloris, foliis quinquepartitis acutis foliolis pinnatifidis. Lin. Sp. Plant. 683. *Crane's-bill with one flower on a foot-stalk, leaves divided into five acute parts, and the smaller leaves wing-pointed.*
17. GERANIUM (*Moschatum*) pedunculis multifloris, floribus pentandris foliis pinnatis incisissimis cotyledonibus pinnatifidis. Burm. Ger. 22. *Crane's-bill with many flowers on each foot-stalk, having five stamina to the flowers, and cut winged leaves.* *Geranium cicutæ folio, moschatum.* C. B. P. *Musked Crane's-bill, frequently called Muscovy.*
18. GERANIUM (*Gruinum*) pedunculis sub multifloris, floribus pentandris, foliis ternatis lobatis. Burm. Ger. 32. *Crane's-bill with many flowers on a foot-stalk, five stamina to the flower, and ternate lobed leaves.* *Geranium latifolium annuum*, cæruleo flore, acu longissimâ. H. Ox. *Broad-leaved annual Crane's-bill with a blue flower, and a very long beak.*
19. GERANIUM (*Ciconium*) pedunculis multifloris, calycibus pentaphyllis, floribus pentandris, foliis pinnatis acutis sinuatis. Lin. Sp. Plant. 680. *Crane's-bill with many flowers on each foot-stalk, having five-leaved empalements, five stamina to the flowers, and acute, sinuated, winged leaves.* *Geranium Cicutæ folio, acu longissimâ.* C. B. P. 319. *Crane's-bill with a Hemlock leaf, and very long beaks to the seed.*
20. GERANIUM (*Viscosum*) pedunculis multifloris, calycibus pentaphyllis, floribus pentandris, foliis bipinnatis multifidis caule erecto. *Crane's-bill with many flowers on each foot-stalk, having five-leaved empalements, flowers with five stamina, and many-pointed winged leaves.* *Geranium cicutæ folio viscosum erectum, acu longissimâ.* Jussieu. *Erect viscos Crane's-bill with a Hemlock leaf, and very long beaks to the seed.*
21. GERANIUM (*Cucullatum*) calycibus monophyllis, foliis cuculatis dentatis. Hort. Cliff. 345. *Crane's-bill with an empalement of one leaf, and indented hooded leaves.* *Geranium Africanum arborescens*, ibisci folio rotundo, carlinæ odore. H. L. *African-tree Crane's-bill with a round Marshmallow leaf, and smell of the Carline Thistle.*
22. GERANIUM (*Angulosum*) calycibus monophyllis, foliis cuculatis angulosis, acutè dentatis. *Crane's-bill*

with a one-leaved empalement, and angular hooded leaves sharply indented. *Geranium Africanum arborescens*, ibisci folio anguloso, floribus amplis purpureis. Phil. Transf. 388. *African-tree Crane's-bill with an angular Marshmallow leaf, and large purple flowers.*

23. GERANIUM (*Zonale*) calycibus monophyllis, foliis cordato-orbiculatis incisissimis zona notatis. Hort. Upsal. 196. *Crane's-bill with a one-leaved empalement, and round heart-shaped leaves, which are cut, and marked with a circle.* *Geranium Africanum arborescens*, alchimillæ hirsuto folio, floribus rubicundis. Com. Præl. *African-tree Crane's-bill with an hairy Ladies Mantle leaf, and red flowers.*
24. GERANIUM (*Inquinans*) calycibus monophyllis, foliis orbiculato-reniformibus tomentosis crenatis integrifolius, caule fruticoso. Hort. Upsal. 195. *Crane's-bill with a one-leaved empalement, and round kidney-shaped leaves which are woolly, crenated, entire, and a shrubby stalk.* *Geranium Africanum arborescens*, malvæ folio plano lucido, flore elegantissimè kermesino. Di van Leur. Boerh. Ind. *African-tree Crane's-bill, with a plain, shining, Mallow leaf, and an elegant scarlet flower.*
25. GERANIUM (*Capitatum*) calycibus monophyllis, foliis lobatis undatis villosis, caule fruticoso. Hort. Upsal. 196. *Crane's bill with empalements of one leaf, leaves divided into lobes, which are waved and hairy, and a shrubby stalk.* *Geranium Africanum frutescens*, malvæ folio odorato laciniato. H. L. *African shrubby Crane's-bill with a jagged, sweet-smelling, Mallow leaf.*
26. GERANIUM (*Vitifolium*) calycibus monophyllis, foliis adscendentibus lobatis pubescentibus, caule fruticoso. Hort. Upsal. 196. *Crane's-bill with one-leaved empalements, ascending leaves which have lobes, are covered with soft hairs, and a shrubby stalk.* *Geranium Africanum frutescens*, malvæ folio laciniato, odorato instar melissæ, flore purpurascens. Boerh. Ind. *African shrubby Crane's-bill, with a jagged Mallow leaf smelling like Balm, and a purplish coloured flower.*
27. GERANIUM (*Papilionaceum*) calycibus monophyllis, corollis papilionaceis, alis carinaque minutis, foliis angulatis, caule fruticoso. Hort. Cliff. 345. *Crane's-bill with an empalement of one leaf, a butterfly flower, whose wings and keel are very small, and a shrubby stalk.* *Geranium Africanum arborescens*, malvæ folio mucronato, petalis florum inferioribus vix conspicuis. Phil. Transf. *African-tree Crane's-bill with a pointed Mallow leaf, and the under petals of the flower scarce discernible.*
28. GERANIUM (*Acetosum*) calycibus monophyllis, foliis glabris obovatis carnosissimis crenatis, caule fruticoso. Hort. Cliff. 345. *Crane's-bill with empalements of one leaf, smooth, oval, fleshy leaves, which are crenated, and a shrubby stalk.* *Geranium Africanum frutescens*, folio crasso & glauco, acetosæ sapore. Com. Præl. *African shrubby Crane's-bill with a thick glaucous leaf, and an acid taste like Sorrel.*
29. GERANIUM (*Carnosum*) calycibus monophyllis, caule fruticoso, articulis carnosissimis gibbosis, foliis pinnatifidis laciniatis, petalis linearibus. Lin. Sp. Plant. 67. *Crane's-bill with an empalement of one leaf, a shrubby stalk with fleshy knees, wing-pointed leaves, and very narrow petals to the flower.* *Geranium Africanum frutescens*, chelidonii folio, petalis florum angustis albidis, carnosissimis caudice. Phil. Transf. *Geranium Africanum*, folio alceæ, flore albo. Boerh. Ind. alt. *African shrubby Crane's-bill with a leaf like the Alcea, the petals of the flower white and narrow, and a fleshy stalk.*
30. GERANIUM (*Gibbosum*) calycibus monophyllis, caule fruticoso, geniculis carnosissimis gibbosis, foliis subpinnatis appositis. Lin. Sp. Plant. 677. *Crane's-bill with a one-leaved empalement, shrubby stalk with fleshy knees, and winged leaves placed opposite.* *Geranium Africanum noctu olens*, tuberosum & nodosum, aquilegiæ foliis. H. L. *African Crane's-bill smelling sweet in the night, with knotty tuberous stalks, and leaves like Columbine.*
31. GERANIUM (*Fulgidum*) calycibus monophyllis, foliis tripartitis incisissimis, intermedia majore umbellis, geminis, caule fruticoso carnosissimis. Lin. Vir. 67. *Crane's-bill*

Ind. 1. p. 263.
- The first sort grows naturally in moist meadows in many parts of England, but is frequently planted in gardens for the beauty of its large blue flowers; of this there is a variety with white flowers, and another with variegated flowers; but these are apt to degenerate to the common sort, if they are raised from seeds, but by parting of their roots they may be continued. It hath a perennial root, which sends up many stalks, which rise near three feet high, garnished with target-shaped leaves, divided into six or seven lobes; these are cut into several acute segments, after the manner of winged leaves, ending in many points. The flowers are produced at the top of the stalks, each foot-stalk sustaining two flowers, whose petals are large and equal; they are of a fine blue colour, and appear in May and June.
- The varieties of this may be preserved by parting of their roots in autumn; they may be planted in almost any soil or situation, and require no other culture but to keep them clean from weeds. They may also be propagated by seeds, but by this method they are very apt to vary in the colour of their flowers. If the seeds of these plants are permitted to scatter, the plants will come up without any farther care.
- The second sort grows naturally in Germany and Switzerland; this hath a thick, fleshy, perennial root,

GER

from which arise several branching stalks, which grow about one foot high, garnished with leaves at each joint, which are divided into five lobes; and are divided at the top into many short segments, which are crenated on their edges; they are of a light green, and smooth. The flowers are produced at the end of the branches, many growing together in a bunch, but each short foot-stalk sustains two flowers. The flowers have swollen empalements, resembling inflated bladders. The petals are pretty large, equal, and of a fine bright purple colour, and the stamina and style are much longer than the petals; the whole plant, when rubbed, emits an agreeable odour. This flowers about the same time with the first sort, and may be propagated and treated in the same manner, the plant being equally hardy.

The third sort grows naturally in many parts of England, but is often admitted into gardens; this hath pretty thick, fleshy, fibrous roots, which grow to a large head, from which arise many stalks, garnished with leaves, divided into five lobes, which are again divided almost to the midrib. The flowers stand upon long hairy foot-stalks, which come out from the side of the stalk, each sustaining one flower, composed of five broad regular petals, which are of a deep purple colour. This sort flowers in June and July; there are two varieties mentioned of this sort as distinct species, one whose stalks grow more erect, and the other hath leaves more deeply divided; but the plants which I have raised from seeds of these do not come up the same as the parent plants, so they are only seminal varieties.

This hath a perennial root, which may be parted in autumn, and thereby propagated; or it may be propagated by seeds, and the plants treated in the same manner as the first.

The fourth sort hath been supposed by some to be only a variety of the third, but it is undoubtedly a distinct species; for I have frequently raised the plants from seeds, which have always proved to be the same. The stalks of this plant are shorter than those of the third, and spread flat on the ground; the leaves are much less, and not so deeply divided, and the flowers much smaller and of a pale colour, marked with purple; it grows naturally in Lancashire and Westmoreland, where I saw it in plenty. This may be propagated and treated in the same manner as the others.

The fifth sort is a perennial plant, of smaller growth than either of the former. It rises with branching stalks about six inches high, garnished with leaves, having three pretty broad lobes, which are undivided, and crenated on their edges: those on the lower part of the stalks are placed opposite, upon pretty long foot-stalks, but the upper leaves sit close to the stalks and are single. The flowers are produced at the end of the stalks, standing together upon two short foot-stalks; they are of a dirty purple colour, and appear in June. It grows naturally in France. This sort may be propagated and treated in the same manner as the first.

The sixth sort grows naturally on the Alps and Helvetian mountains, and is found in some places in the North of England: this hath a perennial root, from which arise several stalks near a foot high, with leaves which are divided into five or six lobes, which are lacinated on their edges; those which grow near the root have long foot-stalks, but those on the upper part of the stalk sit close; the stalk branches out at the top into three or four divisions, each being terminated by two or three foot-stalks, sustaining two flowers of a dark purple colour, with erect petals. This flowers in June, and may be propagated by seeds or parting of the roots, in the same manner as the first sort.

The seventh sort is very like the sixth, but the leaves are larger, the lobes shorter, broader, and not so much cut; they are striped with black; the stalks rise higher, the flowers are larger, and the petals are reflexed. These differences are permanent, so are

GER

sufficient to constitute a specific difference between them. This may be propagated and treated in the same manner as the first sort. It grows naturally on the Alps.

The eighth sort hath a perennial root, which sends up many branching stalks a foot and a half high, garnished with light green leaves; those on the lower part of the stalk hath five lobes, and stand upon long foot-stalks; but those on the upper part have but three lobes, sit closer to the stalks, and are sharply indented on the edges; the flowers stand upon long slender foot-stalks, each sustaining two flowers, composed of five obtuse petals, which are deeply indented at the top; they are of a dull white, with many purple stripes running longitudinally thro' them. These appear in June, and in cool seasons there will be a succession of flowers a great part of July. This sort is very hardy, so may be propagated by dividing of the roots, or from seeds, in the same manner as the first sort.

The ninth sort grows plentifully in the meadows in Lancashire and Westmoreland; this hath a perennial root, which sends out three or four upright stalks about nine inches high, garnished with leaves, having five lobes, which are sawed on their edges; they are placed opposite on the stalks; those on the lower part have pretty long foot-stalks, but those on the upper part sit closer. The flowers are situated on the top of the stalks, standing upon short foot-stalks, each sustaining two pretty large blue flowers, with entire petals. This flowers in May and June, and may be propagated and treated in the same way as the first sort.

The tenth sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the Royal Garden at Paris; this hath a perennial root, from which arise a few weak stalks about nine inches long, garnished with leaves which are round, and divided into five lobes, which are indented at the top, and placed opposite on the stalks. The flowers stand upon pretty long foot-stalks, which come single from the joints of the stalks, each sustaining two purplish flowers with entire petals, having very short empalements. It flowers in June, and may be propagated either from seeds, or by parting of the roots in the same manner as the first sort, but the plants require a drier soil and a warmer situation; for although in common winters it will live in the open air, yet in severe frost these plants are sometimes killed, especially when they are planted in moist cold land.

The eleventh sort grows naturally on the Pyrenean mountains; this hath a perennial root, from which arise many branching stalks a foot and a half high, garnished with round leaves, divided into many obtuse segments at the top, placed opposite. The flowers are produced upon short foot-stalks, which come out at the divisions on the sides, and at the top of the stalks; they are in some of a pale purple colour, and in others white. The petals of the flowers are bifid, like those of the common Dove's-foot Crane's-bill, to which the whole plant bears some resemblance; but the stalks are erect, the leaves and flowers much larger, and the root is perennial; this will propagate itself fast enough by its scattered seeds where it has once got possession, and will thrive in any soil or situation.

The twelfth sort grows naturally upon the Alps. The seeds of this were sent me by Sig. Micheli, of Florence; this hath a perennial root, which runs very deep into the ground. The lower leaves of the plant have very long foot-stalks, they are doubly winged and smooth. The stalks rise a foot and a half high, which are garnished with leaves of the same form as the lower, but smaller, and stand opposite. The flowers grow many together upon very long foot-stalks; they are purple. This flowers in June, but has never ripened any seeds in England. The plant is hardy, and lives in the open air, but as the root puts out no offsets, nor perfects seeds here, we have not been able to propagate it.

The

GER

The thirteenth sort grows naturally on the Alps; this hath a very thick perennial root, from which come out roundish leaves, divided into many parts, standing upon pretty long foot-stalks; they are very silvery, and shining like silk. The flower-stalks rise about four or five inches high, garnished with one or two small leaves like those below, which sit close to the stalk. The stalks are terminated by two pretty large pale flowers, whose petals are entire, and spread open flat. It flowers in June, but rarely ripens seeds here; it may be propagated by parting of the roots in the same manner as the first, and must have a shady situation.

The fourteenth sort grows naturally in North America, from whence the seeds were sent to England; this hath a perennial root, from which arise several stalks about one foot high, which divide by pairs, and from the middle of the divisions come out the foot-stalks of the flowers, which are pretty long and naked, each sustaining two pale purple flowers with entire petals. The leaves are divided into five parts, which are cut on their edges, and are placed opposite, the lower having pretty long foot-stalks, but the upper sit close to the stalks. It flowers in June, and frequently ripens seeds, from which the plant may be propagated; it thrives very well in the open air, and requires no other culture but to keep it clean from weeds.

The fifteenth sort grows naturally in Bohemia; this is an annual plant, which sends out many stalks, dividing into several smaller, which are garnished with leaves divided into five lobes, crenated on their edges; they stand upon long foot-stalks, and are for the most part opposite. The flowers stand by pairs upon pretty long slender foot-stalks, which come out from the side of the stalk; they are of a fine blue colour, and are succeeded by seeds, whose capsules and beaks are black. It flowers most part of summer, and the seeds ripen soon after, which, if permitted to scatter, there will be a supply of plants, which want no other care but to keep them clean from weeds.

The sixteenth sort grows naturally in Siberia. The seeds of this plant were sent me by Sir Charles Linnæus, professor of botany at Upsal; this sort hath a perennial root. The leaves are divided into five acute lobes, which are cut into many sharp wing-like segments on their edges; they are placed opposite, and have long slender foot-stalks. The foot-stalks of the flower come out from the wings of the stalk; they are pretty long, slender, and each sustain one pale purplish flower. This sort flowers in June, and perfects its seeds very well, so may be easily propagated; it will grow on any soil, or in any situation.

The seventeenth sort is an annual plant, which is sometimes found growing naturally in England, but is frequently preserved in gardens for the musky odour of the leaves, which in dry weather is very strong. The leaves of this are irregularly winged, the lobes grow alternate, and are cut into many obtuse segments on their edges. The stalks branch into many divisions, and frequently decline to the ground. The flowers are produced in umbels upon long foot-stalks, which arise from the wings of the stalks; they are small, blue, and have but five stamina in each, their empalements are composed of five leaves. It flowers in May, June, and July, and the seeds ripen soon after; which, if permitted to scatter, there will be a supply of plants without care, which will require no other culture but to keep them clean from weeds, and thin them where they are too close; it will thrive on any soil, or in any situation.

The eighteenth sort grows naturally in Crete; this is an annual plant with very broad leaves, which are cut on their sides regularly, in form of winged leaves, and are crenated on their borders. The flowers are produced on pretty long foot-stalks, which come out from the wings of the stalk; they have five-leaved empalements, and are composed of five entire blue petals; these are succeeded by the largest and longest beaks of any species of this genus yet known. It

GER

flowers in June and July; this ripens seeds very well, and if they are permitted to scatter, the plants will come up without care; or they may be sown in the spring where they are designed to remain, and will require no other culture but to thin them where they are too close, and keep them clean from weeds.

The nineteenth sort grows naturally in Germany and Italy; this is an annual plant, which hath several prostrate stalks near a foot long, garnished with winged leaves, cut into several acute parts, placed opposite. The flowers come out from the wings of the stalk, upon foot-stalks about three inches long; some of these sustain many flowers, but others have no more than two; they are of a pale blue colour, and are succeeded by very long beaks, but not so long or large as those of the former sort; but the seeds of this are frequently used for hygrometers, to shew the moisture of the air: if the seeds of this are permitted to scatter, the plants will come up and thrive without any other care than to keep them clear from weeds, and the plants which come up in autumn will flower early in May, but those which are sown in the spring seldom flower till July. Dr. Linnæus supposes this and the former sort to be the same, but whoever has seen the two plants, cannot doubt of their being distinct species.

The seeds of the twentieth sort were sent to the Chelsea garden by Dr. Jussieu, professor of botany at Paris; this is an annual plant, which hath upright stalks near two feet high, which are garnished with double winged leaves, ending in many points; these are very viscous, and stand opposite. The flowers are produced on long naked foot-stalks, standing many together upon each; they are of a pale blue colour, and have but five stamina; their empalements are composed of five leaves, which end with awns. It flowers in May, June, and July, according to the times when the seeds are sown, and the seeds ripen a month after; this requires no other culture than the two former sorts.

There are several other sorts of annual Geraniums, some of which grow naturally in England, and are troublesome weeds in a garden, others grow naturally in France, Spain, Italy, and Germany, and are preserved in botanic gardens for the sake of variety; but as they are plants of little beauty, they are rarely admitted into other gardens, therefore I shall not trouble the reader with an enumeration of the species, which would swell this article too much; so I shall next treat of the African Crane's-bills, which are preserved in most of the curious gardens, where there is conveniency to screen them from the frost in winter.

The twenty-first sort grows naturally near the Cape of Good Hope; this rises with a shrubby stalk eight or ten feet high, sending out several irregular branches, garnished with roundish leaves, whose sides are erect, so form a sort of hood by the hollow cavity made in the leaf. The base of the leaves are cut in form of a heart-shaped leaf, and from the foot-stalk run many nerves arising from a point, but diverge toward the sides; the borders of the leaves are sharply indented, those on the lower part of the branches have long foot-stalks, and are placed without order on every side, but those on the upper part have shorter foot-stalks, and stand opposite. The flowers are produced in large panicles on the top of the branches; their empalements are of one leaf, deeply cut into five segments, and closely covered with soft hairs. The petals are large, entire, and of a purple blue colour. It flowers in June, July, August, and September, and the flowers are succeeded by seeds, having short hairy beaks.

The twenty-second sort has some appearance of the twenty-first, but the leaves are of a thicker substance, divided into many acute angles, having purple edges, which are acutely indented. The stalks and leaves are very hairy. The branches are not so irregular as those of the former, nor are the bunches of flowers near so large; these differences are permanent in the plants which are raised from seeds, so it is undoubtedly a distinct

a distinct species, though Dr. Linnæus supposes them to be the same.

The twenty-third sort comes from the Cape of Good Hope, but is one of the oldest, and the most common sort in the English gardens; this rises with a shrubby stalk four or five feet high, and divides into a great number of irregular branches, so as to form a large head, which is often eight or ten feet high. The branches are garnished with roundish heart-shaped leaves, indented on their edges in several obtuse segments, which are cut into short teeth at their brims; these have a purplish circle, or mark, like a horse-shoe, through the leaf, going from one side of the base to the other, corresponding with the border of the leaf; these leaves when gently rubbed, have a scent like scalded Apples. The flowers are produced in pretty close bunches, standing upon foot-stalks about five or six inches in length, which come out from the wings of the stalk, toward the end of the branches; they are of a reddish purple colour, and continue in succession great part of summer; there is a variety of this with fine variegated leaves, which is preserved in most of the English gardens for the beauty of its leaves; but as this accidentally came from the other, it is not a distinct species, therefore I have not enumerated it.

The twenty-fourth sort grows naturally at the Cape of Good Hope; this rises with a soft shrubby stem to the height of eight or ten feet, sending out several branches, which are generally erect; these are garnished with roundish kidney-shaped leaves, which are of a thick substance, and of a lucid green, standing on pretty long foot-stalks; they are covered with soft hairs on their under side, and are placed without any order. The flowers grow in loose bunches upon long stiff foot-stalks, which come out from the wings of the stalk; they are of a bright scarlet colour, so make a fine appearance, and there is a succession of these flowers during all the summer months.

The twenty-fifth sort grows naturally at the Cape of Good Hope, but has been many years an inhabitant of the English gardens; this rises with a shrubby stalk four or five feet high, dividing into several weak irregular branches, garnished with leaves divided into three unequal lobes, which are hairy and waved on their edges; they are placed alternate on the branches, and stand upon hairy foot-stalks. The flowers grow in close roundish heads on the top of the foot-stalks, forming a sort of corymbus; they are of a purplish blue colour, and continue in succession great part of the summer. The leaves of this sort, when rubbed, have an odour like dried Roses, from whence many have given it the title of Rose Geranium.

The twenty-sixth sort is a native of the Cape of Good Hope; this rises with an upright shrubby stalk to the height of seven or eight feet, sending out many pretty strong branches, garnished with leaves shaped somewhat like those of the Vine; those on the lower part stand upon long foot-stalks, but the upper have short ones; when the leaves of this are rubbed, they have a scent of Balm. The flowers grow in compact clusters on the top of long naked foot-stalks, which come out from the wings of the stalk, but rise much higher than the branches; they are small, and of a pale blue colour, so make no great figure, but there is a succession of them most part of the summer.

The twenty-seventh sort rises with an upright shrubby stalk seven or eight feet high, sending out several side branches, garnished with large, angular, rough leaves, standing upon long foot-stalks. The flowers are produced in large panicles at the end of the branches; these are shaped somewhat like a Butterfly-flower, the two upper petals, which are pretty large, turn upward like a standard in the leguminous flowers; these are finely variegated, but the three under petals are so small, as not to appear at a small distance; these are reflexed downward, so are screened from sight, unless the flowers are viewed near. This sort flowers in May, at which time the plants make a fine appearance, but they are not succeeded by any

more afterward, as most of the other sorts are; this grows naturally at the Cape of Good Hope.

The twenty-eighth sort is from the same country; this rises with a shrubby stalk six or seven feet high, sending out several side branches, garnished with oblong, oval, fleshy, smooth leaves, of a gray colour, which are crenated on their edges, and have an acid taste, like Sorrel. The flowers stand upon pretty long foot-stalks, which arise from the wings of the stalks, each sustaining three or four flowers, whose petals are narrow and unequal in size; they are of a pale bluish colour, with some stripes of a light red; these continue in succession most part of the summer. There is a variety of this with scarlet flowers, which is said to have been raised from the seeds of this sort. The leaves of it are larger, and seem to be an intermediate species between this and the twenty-fourth sort, for the flowers are larger than those of the twenty-eighth sort, and are of a pale scarlet colour.

The twenty-ninth sort hath a thick, fleshy, knotted stalk, which rises about two feet high, sending out a few slender fleshy branches, garnished thinly with double winged leaves, which, on the lower part of the stalk, stand upon foot-stalks, but those above sit close to the branches. The flowers are produced in small clusters at the end of the branches; these have five narrow white petals, which make no appearance, and continue in succession most part of the summer. It grows naturally at the Cape of Good Hope.

The thirtieth sort hath a round fleshy stalk with swelling knots at the joints, which rise about three feet high, and send out several irregular branches, which are smooth; they are thinly garnished with smooth, fleshy, winged leaves, ending in obtuse points; they are of a gray colour, and stand upon short foot-stalks. The flowers stand four or five upon each foot-stalk, which arises from the wings of the stalk, and are of a dark purple colour. The petals are broader than those of the former sort, and have a very agreeable scent in the evening, after the sun has left them some time; this and the former sort are supposed to be one species by Dr. Linnæus, but they are very different in many particulars, which are permanent in the plants which come up from seeds.

The thirty-first sort hath a fleshy stalk which seldom rises a foot high, and puts out very few branches; these are garnished with smooth, light, green leaves, divided into three lobes, the middle segment being much larger than the others. The flowers stand upon short foot-stalks, each sustaining two or three flowers on the top, which are of a very deep scarlet colour, and have unequal petals; this sort is not regular in its season of flowering, sometimes it is in spring, at other times in summer, and frequently in autumn. The leaves of this sort fall off, so that the stalks are frequently destitute of them for three or four months in summer, and appear as if they were dead, but in autumn they put out fresh leaves again.

The thirty-second sort hath many weak shrubby stalks, which require support to prevent their falling on the ground; these extend to the length of two or three feet, and are garnished with fleshy leaves, divided into five obtuse lobes, which are entire; these have slender foot-stalks, which are fastened to the middle of the leaf like the handle of a target. The leaves are smooth, of a lucid green, and have a circular purple mark in their middle; they have an acid flavour, and are placed alternate on their branches. The flowers are produced upon pretty long foot-stalks, which come out from the wings of the stalk, each foot-stalk sustaining four or five purple flowers, composed of five unequal petals. This sort continues a succession of flowers most of the summer months, and frequently ripen seeds here.

The thirty-third sort sends out several herbaceous stalks about a foot and a half in length, which trail upon the ground if they are not supported; these are garnished with roundish hand-shaped leaves, which are cut into many parts, and are very hairy. The flowers are of a pale bluish colour, and stand several together

together upon very long foot-stalks; there is a succession of these during all the summer months, and the seeds ripen accordingly about a month after the flowers are fallen: there is a variety of this sort which has a dark circle in the middle of the leaves, which is mentioned as a distinct species, but I find it is apt to vary from seeds.

The thirty-fourth sort hath a very short fleshy stalk, which divides near the ground into several heads, each having many leaves, which arise on separate foot-stalks from the heads; these are heart-shaped, soft, and downy, and have a strong scent like Aniseed; from these heads come out several slender stalks near a foot in length, which lie prostrate on the ground, and are garnished with rounder leaves than those near the root, but are of the same texture, and have the like odour. The flowers are produced from the side of these stalks, three, four, or five standing together upon slender foot-stalks; they are very small and white, so make little appearance, but the plant is preserved in gardens for the scent of its leaves.

The thirty-fifth sort hath a thick, roundish, tuberous root, from which arise several hairy leaves, which are finely divided, almost like those of the Garden Carrot; these spread near the ground, and between these come out the stalks, which rise about a foot high, which are garnished with two or three leaves of the same sort with those below, but are smaller, and sit closer to the stalks; from these arise two or three naked foot-stalks, which are terminated by a bunch of yellowish flowers, marked with dark purple spots, which smell very sweet after the sun hath left them; these are frequently succeeded by seeds, which ripen in autumn. This is the sort which has been long cultivated in the gardens, and is known by the title of *Geranium noctu olens*, or *Night-scented Crane's-bill*.

The thirty-sixth sort hath a knobbed tuberous root like the last, from which come out several pretty large leaves, composed of many lobes, set along the midrib in the form of a winged leaf; these are narrow at their base, but are very much enlarged at their ends, which are rounded, and cut all along their side and top into many acute points; the stalks which sustain the flowers arise immediately from the root, and sometimes have one or two small leaves toward the bottom, where they often divide into two naked foot-stalks, each being terminated by a bunch of pale reddish flowers, which smell sweet at night.

The thirty-seventh sort hath oblong tuberous roots, from which come out several compounded winged leaves, ending in many acute points; the segments of these leaves are broader than those of the thirty-fifth sort, and the leaves are very hairy. The stalks rise a foot and a half high, which are garnished with a single leaf at the two lower joints; these are singly winged, and the lobes are narrow, standing at a wider distance, and the segments are more acute than those of the lower leaves; at the two lower knots or joints, arise two long naked foot-stalks, each being terminated by a bunch of yellowish flowers, which have long tubes, and smell sweet in the evening when the sun has left them. This grows naturally at the Cape of Good Hope.

The thirty-eighth sort hath a tuberous root like the former, from which spring out many hairy leaves, which are finely divided like those of the *Pulsatilla*, which have a hoary appearance, and rise immediately from the root, spreading on every side near the ground. The foot-stalk of the flower is naked, and rises from the root; this grows about nine inches high, and is terminated by a loose bunch of flowers, which are of a very dark purple colour, and smell sweet in the evening.

The thirty-ninth sort hath fleshy tuberous roots like those of the former sorts, from which come out three or four broad leaves, divided on their borders into several lobes, in form of a Vine leaf; these spread flat on the ground; they are hairy, and crenated on their edges, standing upon short foot-stalks. The foot-stalks of the flowers arise immediately from the root,

and grow about a foot high; they are naked, and are terminated by a bunch of dark purple flowers, with long tubes, sitting close to the foot-stalks, which have a very agreeable odour in the evening.

The four first sorts of tuberous-rooted Crane's-bill, are by Linnæus supposed to be but one species; but I have propagated them from seeds several times, and have never found either of them vary from their parent plants, so I make no doubt of their being distinct species, for their difference of leaves is as great as in any of the other species.

The fortieth sort is an annual plant, which grows naturally at the Cape of Good Hope; this rises with herbaceous branching stalks near a foot high, which are garnished with doubly-winged leaves at each joint; the lower leaves stand upon long foot-stalks, but those on the upper part sit close to the stalks. The flowers stand upon naked foot-stalks, which proceed from the side of the stalks, on the opposite side to the leaves; they grow three or four together upon short separate foot-stalks; these are shaped somewhat like a papilionaceous flower; the two upper petals, which are large, form a kind of standard, the other three petals are narrow, and reflexed downward; they are of a pale flesh colour, appearing in July, and the seeds ripen in September, soon after which the plants decay.

The forty-first sort hath a pretty thick tuberous root, from which is sent out several irregular stalks, which divide into branches, and grow diffused; these have swelling joints, and are somewhat ligneous; they are garnished with one double winged leaf at each of the joints, and opposite to the leaves come out the foot-stalks of the flowers; those which are situated on the lower part of the stalk, are very long and naked, but those which terminate the branches are shorter, and have one or two small leaves set at their base; these foot-stalks are terminated by a small bunch of flowers, shaped like those of the former sort, but larger, and of a paler colour; these continue in succession most part of the summer: this and the former sort are supposed to be the same by Dr. Linnæus, but the former is an annual plant in every country, perishing soon after the seeds are perfected, and the latter is an abiding plant with ligneous stalks.

The forty-second sort is a biennial plant, which grows naturally at the Cape of Good Hope; this sends out a great number of very slender trailing stalks, which are prostrate on the ground, and extend a foot and a half in length, garnished with small, roundish, hand-shaped leaves, which are crenated on their edges. The flowers sit upon short slender foot-stalks, which come out at every joint from the side of the stalks; they are very small, and of a reddish colour; sometimes they are single, and at other times there are two or three flowers upon a foot-stalk. They continue in succession all the summer, and the seeds ripen in about five weeks after the flowers decay.

The forty-third sort hath a shrubby stalk, which rises to the height of four or five feet, sending out several branches, which are garnished with oblong leaves, indented, and unequally sawed on their edges; the flowers stand upon long foot-stalks, which come out from the side of their branches; they are large, of a red colour, and the two upper petals are larger than the other; this sort flowers in June and July.

The forty-fourth sort grows naturally in the isle of Chio in the Levant. This is an annual plant, which sends out several branches a foot long; the lower leaves are almost heart-shaped, but those on the branches are formed in the shape of an ancient lyre. These are placed alternate on the branches; the foot-stalks of flowers are produced on the side of the branches, these are six inches long, sustaining many bright purple flowers at the top, which are succeeded each by five seeds, having long slender beaks; these ripen in five or six weeks after the flowers fall away, and if they are permitted to scatter, the young plants will come up in the autumn; and if the winter is favourable, they will live in the open air, so will flower early the

following spring: but if these should be killed in the winter, some seeds should be sown in the spring, on a border of light ground, and when the plants come up they should be thinned, and kept clear from weeds; these will flower in July, and their seeds will ripen in August.

The forty-fifth sort grows naturally in Portugal and Spain; this is an annual plant, whose lower leaves are heart-shaped, and divided into three lobes; the foot-stalks of the flowers are placed on the side of the branches, which extend a foot and a half each way; these incline to the ground. The foot-stalks sustain many bright red flowers, which are succeeded each by five seeds, having pretty long beaks. This flowers and seeds about the same time as the former sort, and requires the same culture.

The forty-sixth sort grows naturally in Egypt. This is an annual plant, having oval sawed leaves of a gray colour; the branches extend a foot in length, adorned with small leaves placed alternate, and toward the end have three or four foot-stalks produced from their sides, sustaining several pale blue flowers, which are each succeeded by five seeds, having long feathery beaks.

This sort is much tenderer than the two former, therefore if the seeds are sown on a moderate hot-bed in the spring, and when the weather becomes warm, the plants are carefully transplanted on a sheltered border, there will be greater certainty of their perfecting seeds.

The forty-seventh sort grows naturally in Carolina, and is an annual plant, greatly resembling our common Dove's-foot Crane's-bill, but is smaller, and the branches are shorter; the flowers are very small, of a pale blue colour; these are succeeded by five seeds, having short erect beaks, which are black. If the seeds of this sort are permitted to scatter, the plants will arise without farther care; and if thinned and kept clean from weeds, will produce flowers and seeds.

The forty-eighth sort has some resemblance of the forty-fifth, but the leaves are more of an oval heart-shape; the flowers are also of a bright red colour. This grows naturally at the Cape of Good Hope; the plant is tender, therefore will require the same treatment as the forty-seventh sort, with which they will produce flowers and seeds, after which the plants decay.

All the sorts of African Crane's-bill may be propagated by seeds; these may be sown upon a bed of light earth toward the end of March, where the plants will appear in a month or five weeks after, and by the beginning of June the plants will be fit to remove; when they should be carefully taken up, and each planted into a separate pot, filled with light kitchen-garden earth, and placed in a shady situation till the plants have taken new root; then they may be removed into a sheltered situation, and placed among other of the hardier green-house plants, where they may remain till autumn, when they must be removed into the green-house, and treated in the same manner as other hardy kinds of green-house plants.

But those who are desirous to have their plants large, and flower soon, sow the seeds upon a moderate hot-bed in the spring, on which the plants will come up much sooner, and will be fit to remove long before those which are sown in the open air; but when these plants come up, there must be great care taken not to draw them up weak; and when these are transplanted, the pots should be plunged into another moderate hot-bed, observing to shade them from the sun till they have taken new root; then they must be gradually inured to bear the open air, into which they should be removed the beginning of June, and placed in a sheltered situation with other exotic plants. If these plants are brought forward in the spring, most of the sorts will flower the same summer, and the plants will be very strong before the winter, so will make a better appearance in the green-house.

The shrubby African Geraniums, from the twenty-first to the thirty-second inclusive, and also the for-

ty-first and forty-third sorts, are commonly propagated by cuttings, which, if planted in a shady border in June or July, will take good root in five or six weeks, and may then be taken up and planted into separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated in the same manner as the seedling plants. The twenty-ninth, thirtieth, thirty-first, and thirty-second sorts, have more succulent stalks than either of the other, so the cuttings of these sorts should be planted into pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun in the heat of the day, and should have but little water; for these are very apt to rot with much moisture, so they must only be gently refreshed now and then with water. When these are well rooted, they may be separated and planted in pots filled with the same sort of earth, and placed in the shade till they have taken new root; then they may be removed into a sheltered situation, where they may remain till autumn. These four sorts should be sparingly watered at all times, but especially in the winter, for they are apt to take a mouldiness with moisture, or in a damp air: they will thrive much better in an airy glass-case than in a green-house, because in the former they will have more sun and air than in the latter, so will not be so liable to have a mouldiness or rot. But all the other shrubby sorts are proper furniture for the green-house, where they will only require protection from frost, but should have a large share of free air when the weather is mild; they will require water every week, in mild weather once or twice, but it should not be given them in too great plenty, especially in frosty weather. These plants should be hardened in the spring gradually, and toward the middle or latter end of May, they may be taken out of the green-house, and at first placed under the shelter of trees, where they may remain a fortnight or three weeks to harden; then should be removed into a situation where they may be defended from strong winds, and enjoy the morning sun till eleven o'clock, where they will thrive better than in a warmer situation.

As these shrubby sorts grow pretty fast, so they soon fill the pots with their roots; and if they stand long unremoved in summer, they frequently put out their roots through the holes at the bottom of the pots into the ground, and then the plants will grow vigorously; but when they are suffered to grow long in this manner, it will be difficult to remove them, for if their roots are torn off, all the younger branches will decay, and many times the plants are killed. Therefore the pots should be moved once in a fortnight or three weeks, in the summer months, and the roots which may be then pushing through the holes in the pots cut off, to prevent their striking into the ground. These plants will also require to be new potted at least twice in the summer; the first time should be after they have been three weeks or a month out of the green-house; the second should be towards the end of August, or the beginning of September, that the plants may have time to establish their new roots before they are removed into the green-house.

When these are new potted, all the roots on the outside of the balls of earth should be carefully pared off, and as much of the old earth drawn away from the roots, as can be done with safety to the plants; then if they require it, they should be put into pots a size larger than those out of which they were taken, putting a quantity of fresh earth into the bottom of the pot; then place the plants upon that, being careful the ball about the roots of the plant is not so high as the rim of the pot, that some room may be left to contain the water which may be given to the plants. Then the cavity all round the ball should be filled up with fresh earth, which should be gently pressed down, and the bottom of the pot beaten upon the ground, to settle down the earth; then the plant should be well watered, and the stem fastened to a rail, to prevent the

the wind from displacing of the root before they are fixed in the new earth.

The compost in which I have always found these plants thrive best (where there has not been a convenience of getting some good kitchen-garden earth) was fresh hazel loam from a pasture, mixed with a fourth or fifth part of rotten dung; if the earth is inclinable to bind, then a mixture of rotten tan is preferable to dung; but if it is light and warm, then a mixture of neat's-dung is best: this compost should be mixed three or four months before it is used, and should be turned over three or four times, that the parts may be well mixed and incorporated; but where a quantity of good kitchen-garden earth can be had, which has been well worked, and is clean from the roots of bad weeds, there will need no composition, for in that they will thrive full as well as in any mixture which can be made for them, especially if the earth has lain in a heap for some time, and has been two or three times turned over to break the clods, and make it fine: these plants should not be planted in very rich earth, for that will cause them to grow very luxuriant, but they will not flower so well as in a poorer soil.

The thirty-third sort hath herbaceous stalks, so is best propagated by seeds, which the plants produce in great plenty; but the cuttings of this will take root as freely as either of the other, but the seedling plants are preferable to those propagated by cuttings; and where the seeds of this and many other of the African sorts are permitted to scatter, there will be a supply of young plants come up the spring following, provided the seeds are not buried too deep in the ground. The thirty-fourth sort may be propagated by seeds, or from heads slipped off from the short fleshy stalk; these heads should have their lower leaves stripped off, that the stalk which is to be planted may be clear of leaves; then they may be planted single into a small pot, or if the heads are small, there may be two or three put into one small pot; then they may be plunged into a very moderate hot-bed, which will forward their putting out roots, and if they are shaded from the sun and gently refreshed with water, they will take root in a month or five weeks, when they must be hardened gradually, and removed into the open air, where they may remain till autumn, when they must be removed into shelter for the winter season.

The thirty-fifth, thirty-sixth, thirty-seventh, thirty-eighth and thirty-ninth sorts are generally propagated by parting of their roots; the best time for doing this is in August, that the young roots may be established before the cold comes on. Every tuber of these roots will grow, provided they have a bud or eye to them; they may be planted in the same sort of earth as was before directed, and if the pots are plunged into an old tan-bed, under a good frame in winter, the plants will thrive better than in a greenhouse; the glasses of the frame may be drawn off every day in mild weather, whereby the plants will enjoy the free air; and if in hard frost the glasses are well covered to prevent the cold penetrating to the plants, it is all the shelter they will require; but in this situation they should have but little wet in winter, therefore the glasses should be kept over them in heavy rains to keep them dry; but in mild weather the glasses may be raised on the upper side to admit the fresh air to the plants, which will give them greater slope to carry off the wet. With this management the roots will thrive and flower very strong every year. These sorts may also be propagated by seeds.

The fortieth sort is an annual plant, and is only propagated by seeds, which should be sown upon a gentle hot-bed in the spring, to bring the plants forward; otherwise if the season should not prove very warm, the plants will not perfect their seeds in this country. When the plants are come up, and grown strong enough to remove, they should be each planted into a separate small pot, and plunged into a moderate hot-bed again, observing to shade them till they have

taken new root; then they must be gradually hardened to bear the open air, into which they should be removed in June; and when the plants have filled the small pots with their roots, they should be shaken out, and the ball of earth preserved to their roots, and put into pots a size larger, in which they will flower and ripen seeds, and soon after the plants will decay.

The forty-second sort is also propagated by seeds, which may be either sown upon a moderate hot-bed in the spring, or upon a bed of light earth in the open air, where the plants will come up very well, though they will not be so forward as those on the hot-bed. Those which are sown in the open air will require no other care but to keep them clean from weeds, and thin the plants where they are too close. These plants will flower in July and August, and if the autumn proves favourable, the seeds will ripen in September; but if these should fail, those which were raised on the hot-bed will come earlier to flower, so there will be no danger of their perfecting seeds; and these plants, if they are in pots, may be preserved through the winter, if they are plunged into an old tan-bed under a frame, and treated in the same manner as the tuberous-rooted sorts before mentioned.

The shrubby sorts must be looked over frequently during the winter, while they are in the greenhouse, to pick off all decayed leaves from them, which, if left on, will not only render the plants unsightly, but by their falling off, they will occasion litter among the other plants; and if they are suffered to rot in the house, they will occasion a foul, nasty, damp air, which will be very prejudicial to all the plants; therefore to avoid this, they should be constantly picked off every week; and during the summer season, they will require to be picked every fortnight or three weeks to keep them clean from dead leaves; for as the branches advance, and new leaves are produced on their top, the under ones as constantly decay; and if left on till they drop off, will render the plants very unsightly.

GERMANDER. See TRUCRIUM.

GEROPOGON. Goat's-beard.

The CHARACTERS are,

The empalement is single, composed of many keel-shaped leaves which are longer than the corolla; the flower is composed of several hermaphrodite florets, which are imbricated and shorter than the empalement, and are of one petal, divided into five segments at the top. These have each five short stamina, terminated by cylindrical summits, and an oblong germen with a slender style, supporting two thread-like stigma which are recurved; the seeds are included in the empalement, and are crowned by five bearded spreading rays.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Æqualis, the florets having five connected stamina, and are fruitful.

The SPECIES are,

1. GEROPOGON (*Glabrum*) foliis glabris. Lin. Sp. 1109. Goat's-beard with smooth leaves. Tragopogon gramineo folio glabrum, flore dilute incarnato. Raii Sup. 149.
2. GEROPOGON (*Hirsutum*) foliis pilosis. Lin. Sp. 1109. Goat's-beard with hairy leaves. Tragopogon gramineo folio, suave rubente flore. Col. Ecphr. 1. p. 232.

The first sort grows naturally in Italy; this hath an erect stalk more than a foot high, garnished with smooth, Grass-like, long leaves; the stalk branches upward into two or three divisions, each being terminated by one flesh-coloured flower, composed of several florets.

The second sort grows naturally in Italy and Sicily. This rises with an erect stalk a foot high, garnished with hairy narrow leaves, and seldom divides into branches, but is terminated by one flower composed of four or five hermaphrodite florets, which are succeeded by so many bearded seeds.

These plants require the same treatment as the TRAPOGON, to which article the reader is desired to turn for their culture.

GESNERA A. Plumier Nov. Gen. 27. tab. 9. Lin. Gen. Plant. 667. This plant was so named by father Plumier, who discovered it in America, in honour of Conrad Gefner, a very learned botanist, and natural historian.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five acute parts at the top, and is permanent, in which is situated the germen; the flower hath one petal which is tubulous, and first bent inward, and afterward out again like a bugle-horn; the brim is divided into five obtuse segments which are equal; it hath four stamina which are shorter than the petal, terminated by single summits; the germen which sits under the petal supports a single crooked style, crowned by a beaded stigma. The germen afterward becomes a roundish capsule with two cells, filled with small seeds, which are fixed on each side the partition.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, which includes those plants whose flowers have two long and two shorter stamina, and the seeds are included in a capsule.

The SPECIES are,

1. **GESNERA** (*Tomentosa*) foliis ovato-lanceolatis crenatis hirsutis, pedunculis lateralibus longissimis corymbiferis. Hort. Cliff. 318. *Gesnera with oval, hairy, crenated leaves, and long foot-stalks proceeding from the sides of the stalks, supporting flowers in a corymbus.* Gesnera amplo digitalis folio tomentoso. Plum. Gen. 27.
2. **GESNERA** (*Humilis*) foliis lanceolatis serratis sessilibus, pedunculis ramosis multifloris. Lin. Sp. Plant. 612. *Gesnera with spear-shaped sawed leaves sitting close to the stalks, and branching foot-stalks having many flowers.* Gesnera humilis flore flavescens. Plum. Nov. Gen. 27. *Low Gesnera with a yellowish flower.*

The first sort grows naturally in the West-Indies; the seeds of this were sent me from Jamaica, which succeeded in the Chelsea garden; this rises with a shrubby stalk to the height of six or seven feet, which divides into two or three irregular branches, covered with a russet wool, and garnished with hairy leaves which are seven or eight inches long, and two and a half broad in the middle, having a russet woolly midrib, and the edges are crenated; these are placed on every side the branches without order, and have short foot-stalks; towards the end of the branches come out the foot-stalks of the flowers at every joint, arising from the wings of the stalk; they are naked, and nine inches in length, branching at the top into many smaller foot-stalks, each sustaining a single flower, having a short crooked tube, indented at the top in five obtuse parts, and of an obsolete purple colour. These are succeeded by roundish capsules sitting close in the empalement, the divisions of which arise above the capsule; which Dr. Linnæus, from Plumier's figure, has taken for the empalement sitting upon the capsule, whereas the capsule is distinct from the empalement and is inclosed by it. The capsule is divided into two cells which are filled with small seeds. It flowers here in July and August, but hath not ripened seeds.

The second sort is a plant of humbler growth; this seldom rises more than three feet high; the leaves are much smaller, are sawed on their edges, and sit close to the stalk; the flowers stand upon branching foot-stalks, each sustaining many yellowish flowers, which are deeper cut at their brims than those of the first sort. This was found growing naturally by the late Dr. Houstoun at Carthagen in New Spain.

There is a third species of this genus mentioned by Plumier, which grows to a tree, and hath spotted and fringed flowers; but this I have not seen in any of the English gardens. These plants are propagated by seeds, which must be procured from the countries where they grow naturally; these should be brought over in their capsules, which is the best way to preserve the seeds good; for as they are very small and light, so when they are separated from the partition to which they adhere, they soon lose their vegetative quality; for I have received the seeds se-

veral times from America, which were taken out of the vessels, but not one of them grew, till I procured some to be sent in their vessels, which succeeded very well.

The seeds should be sown in pots filled with light earth, and plunged into a hot-bed of tanners bark as soon as they arrive, for they sometimes lie long in the ground; those which I have sown in autumn, came up the following spring; therefore when they happen to arrive here at that season, the pots in which the seeds are sown should be plunged into the tan-bed in the stove, and during the winter the earth should be now and then gently watered to prevent its drying too much, but it must not be too moist. In the spring the pots should be removed out of the stove, and plunged into a fresh hot-bed, which will bring up the plants soon after. When these are fit to remove, they should be each planted into a separate pot, and plunged into a good hot-bed of tan, observing to shade them till they have taken new root; then they must be treated in the same way as other tender plants from the same countries.

In autumn they must be plunged into the tan-bed in the stove, where, during the winter, they should have but little water given to them; for if they receive much wet, it will destroy them. In this stove the plants must constantly remain, for they will not thrive if they are kept out of the tan. In the summer, they should have free air admitted to them at all times when the weather is warm; and they must be frequently refreshed with water during that season, but it must not be given to them in too great plenty. As the plants advance in growth they will require larger pots, but there must be care taken not to over-pot them, for they will not thrive in large pots. With this management the plants will flower the second year, and may be continued three or four years, but they are not of long duration in their native country.

GEUM M. Lin. Gen. Plant. 561. Caryophyllata. Tourn. Inst. R. H. 294. tab. 151. Avens, or Herb Bennet; in French, *Benoîte*.

The CHARACTERS are,

The flower hath a one-leaved empalement, cut at the top into ten segments, which are alternately smaller than the other. The flower has five roundish petals, which are narrow at their base, where they are inserted in the empalement; it hath a great number of awl-shaped stamina, which are the length of the empalement, into which they are inserted, and are terminated by broad obtuse summits. In the center of the flower is situated a great number of germen collected into a head; these have styles inserted in their sides, which are long, hairy, and crowned by single stigmas. The germen afterward become so many flat rough seeds, which are hairy, and have the style which is bent like a knee adhering to them; these sit in the common empalement.

This genus of plants is ranged in the fifth section of Linnæus's twelfth class, intitled Icosandria Polygynia, in which he places those plants whose flowers have more than twenty stamina, and have many styles inserted into the empalement.

The SPECIES are,

1. **GEUM** (*Urbanum*) floribus erectis, fructu globofo, aristis uncinatis nudis, foliis lyratis. Hort. Cliff. 195. *Geum with erect flowers, a globular fruit, naked hooked beards, and harp-shaped leaves.* Caryophyllata vulgaris. C. B. P. 321. *Common Avens, or Herb Bennet.*
2. **GEUM** (*Rivale*) floribus nutantibus, fructu oblongo, aristis plumosis. Hort. Cliff. 195. *Geum with nodding flowers, and an oblong fruit with feathery beards.* Caryophyllata aquatica, nutante flore. C. B. P. 321. *Aquatic Herb Bennet with a nodding flower.*
3. **GEUM** (*Pyrenaicum*) floribus nutantibus, fructu globofo, aristis nudis, foliis lyratis, foliolis rotundioribus. *Geum with nodding flowers, a globular fruit with naked beards, and harp-shaped leaves with rounder lobes.* Caryophyllata Pyrenaica, amplissimo & rotundiori folio, nutante flore. Tourn. Inst. R. H. 295. *Pyrenean Avens*

Avens with a very large and rounder leaf, and a nodding flower.

4. **GEUM** (*Montanum*) flore erecto solitario fructu oblongo, aristis plumosis. Lin. Sp. Plant. 501. *Geum with a single upright flower, and an oblong fruit with feathery beards.* Caryophyllata montana flore luteo magno. J. B. 2. p. 398. *Mountain Avens with a large yellow flower.*
5. **GEUM** (*Alpinum*) flore solitario erecto, fructu globoso, aristis tenuioribus nudis. *Geum with a single erect flower, and a globular fruit with narrower naked beards.* Caryophyllata alpina minor. C. B. P. 322. *Smaller Alpine Avens.*
6. **GEUM** (*Virginianum*) floribus erectis, fructu globoso, aristis uncinatis nudis, foliis ternatis. Hort. Cliff. 195. *Geum with upright flowers, a globular fruit with naked beards and trifoliate leaves.* Caryophyllata Virginiana, albo flore minore, radice inodora, H. L. 111. *Virginia Avens with a smaller white flower, and a root without scent.*

The first sort grows plentifully by the side of hedges, and in woods, in most parts of England, so is rarely admitted into gardens. This stands in the list of medicinal plants; the root is the only part used, which is esteemed cephalic and alexipharmic, and is manifestly of a binding nature, so is useful in all fluxes, &c.

The second sort grows naturally in moist meadows in the northern parts of England. This is of an humbler growth than the first, the lower leaves have two pair of small lobes at bottom, and three large ones at the top, that which terminates being the largest. The leaves upon the stalks are composed of three acute lobes which sit close to the stalk; the flowers are of a purplish colour, and nod on one side; they appear in May, and the seeds ripen in July.

The third sort grows upon the Alps, and also on the mountains in the north; this hath some resemblance to the second, but the leaves are much larger and rounder, and are indented on their edges; the flowers are larger and of a gold colour. This flowers about the same time as the second.

The fourth sort grows naturally upon the Alps; this hath leaves much larger than either of the other species; the lower leaves are composed of three or four pair of small irregular pinnæ set along the midrib, which is terminated by one very broad roundish lobe, which is crenated on the edge. The flowers are large, of a bright yellow colour, standing single on the top of the stalk, which seldom rises more than five or six inches high. It flowers in May and June.

The fifth sort grows naturally on the Alps; it is a very low plant, the flower-stalks are about three inches long, and bend on one side; they are each terminated by one bright yellow flower, about the size of those of the common sort. This flowers about the same time as the former.

The sixth sort grows naturally in North America; the stalks of this sort rise a foot and a half or two feet high, and branch out at the top into small foot-stalks, each being terminated by a small white flower; the leaves of this sort are trifoliate, and the root has no scent. These are all very hardy plants which require a shady situation, but will thrive in any soil; they may be easily propagated by seeds, which should be sown in autumn; for when they are sown in the spring, they do not grow the same year.

GILLIFLOWER, or JULY-FLOWER. See **DIANTHUS**.

GILLIFLOWER, or STOCK-GILLIFLOWER. See **CHEIRANTHUS**.

GLADE is an open and light passage made through a wood, by lopping off the branches of trees along that way.

GLADIOLUS. Lin. Gen. Plant. 55. Tourn. Inst. R. H. 365. tab. 190. [takes its name of Gladius, Lat.

sword; q. d. little sword; because the leaves of this plant resemble a sword.] Cornflag; in French, *Glaicul*.

The CHARACTERS are,

The flowers are included in sheaths, which stand at a distance from each other; the petal of the flower is cut into six parts, three of the upper are near together, the three under spread open, but they all form a short incurved tube with their base; they have three awl-shaped stamina, which are inserted into every other petal, and all of them ascend to the upper petals, and are terminated by oblong summits. The germen is situated below the flower, supporting a single style the length of the stamina, crowned by a concave trifid stigma. The germen afterward becomes an oblong, swelling, three-cornered capsule, with three cells, opening with three valves, filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's third class, intitled Triandria Monogynia, which includes those plants whose flowers have three stamina and one style.

The SPECIES are,

1. **GLADIOLUS** (*Communis*) foliis ensiformibus, floribus distantibus, Lin. Sp. Plant. 36. *Cornflag with sword-shaped leaves and flowers standing at a distance.* Gladiolus floribus uno versu dispositis. C. B. P. 41. *Cornflag with flowers disposed on one side the stalk.*
2. **GLADIOLUS** (*Italicus*) foliis ensiformibus, floribus antipitibus. *Cornflag with sword-shaped leaves, and flowers standing on both sides the stalk.* Gladiolus utrinque floribus. C. B. P. 41. *Cornflag with flowers on each side the stalk.*
3. **GLADIOLUS** (*Byzantinus*) foliis ensiformibus, spathis longioribus. *Cornflag with sword-shaped leaves and longer sheaths to the flowers.* Gladiolus major Byzantinus. C. B. P. 41. *Greater Cornflag of Byzantium.*
4. **GLADIOLUS** (*Indicus*) foliis ensiformibus, floribus maximis incarnatis. *Cornflag with sword-shaped leaves, and very large incarnate flowers.* Gladiolus maximus Indicus. C. B. P. 41. *Greatest Indian Cornflag.*
5. **GLADIOLUS** (*Angustis*) foliis linearibus floribus distantibus, corollarum tubo limbis longiore. Lin. Sp. Plant. 37. *Cornflag with very narrow leaves, flowers standing at a distance from each other, and the tube longer than the margins of the petal.* Gladiolus Africanus, folio gramineo, floribus carneis, maculam rhomboideam inscriptis uno versu positus. Boerh. Ind. alt. 2. 127. *African Cornflag, with a grassy leaf, and flesh-coloured flowers, marked with a purple rhomboid spot ranged all on one side the stalk.*
6. **GLADIOLUS** (*Tristis*) foliis lineari cancellatis corollis campanulatis. *Cornflag with very narrow channelled leaves, and a stalk bearing bell-shaped flowers.* Lilio-Gladiolus bifolius & biflorus, foliis quadrangulis. Trew. tab. 39. *Lily Cornflag with two leaves and flowers, and four-cornered leaves.*

The first sort grows naturally in arable land in most of the warm countries in Europe, and was formerly cultivated in the English gardens, where the roots have multiplied so greatly as to become a most troublesome weed, and are very difficult to eradicate; this hath a round, compressed, tuberous root, which is of a yellowish colour, covered with a brown furrowed skin, like those of the large yellow vernal Crocus; from the root arise two flat sword-shaped leaves, which embrace each other at their base, and between these arise the flower-stalk, which grows near two feet high, having one or two narrow leaves embracing it like a sheath; the stalks are terminated by five or six purple flowers, standing above each other at some distance, and ranged on one side of the stalk; each of these has a spatha (or sheath) which covers the flower-bud before it expands, but splits open lengthways when the flowers blow, and shrivel up to a dry skin, remaining about the seed-vessel till the seeds are ripe. The flower hath one petal, which is cut almost to the bottom in six parts, so as to appear like a flower of six petals; the three upper segments stand near together, and rise like a labiated flower; the under one turns downward, and the two side segments form the chaps of the flower, and spread open at the top,

but are curved downward at the bottom. They are ranged along one side of the stalk, and are of a purplish red colour. This flowers the latter end of May, and in June, and the seeds ripen the beginning of August; it requires no care, for when it is once planted in a garden, it will multiply too fast, so as to become a troublesome weed.

There is a variety of this with white flowers, and another with flesh-coloured flowers, which have accidentally risen from seeds, so are not different species.

The second sort differs from the first, in having the flowers ranged on both sides the stalk, but in other respects it is very like to that; and of this there is a variety with white flowers, but these are not so common in the English gardens as the former.

The third sort hath larger roots than either of the former, but are of the same form; the leaves are also much broader and longer, the veins or channels of the leaves are deeper, the flower-stalks rise higher; the flowers are much larger, and of a deeper red colour than those of the former sorts, and the sheaths are longer. This plant makes a fine appearance in flower, so is worthy of a place in every good garden; and the rather, because the roots do not increase so fast as to become troublesome in the borders. This is propagated by offsets, which are sent off from the roots in the same manner as Tulips. The roots may be taken out of the ground the end of July, when their stalks decay, and may be kept out of the ground till the latter end of September, or the beginning of October, at which time they should be planted in the borders of the flower-garden, where they will thrive in any situation, and being intermixed with other flowers of the same growth, they will add to the variety.

The fourth sort grows naturally at the Cape of Good Hope, from whence I have several times received the seeds. This has been many years cultivated in the English gardens, but very rarely flowers here; for in near thirty years that I have cultivated this sort, I have never seen it but once in flower, though I have kept it in all situations, and planted it in various soils. The roots increase very fast, but will not live in the open air through the winter in this country. The roots of this sort are broader and flatter than those of any of the other sorts, and are covered with a netted skin; the leaves come out in the same manner, embracing each other like the former sorts; they are longer, smoother, and of a brighter green, than any of the others; these begin to appear in September, and continue growing in size till after Christmas; they begin to decay in March, and the latter end of June are quite withered, when the roots may be taken up, and kept out of the ground till August; the time of its flowering is in January. The flowers of this sort are placed on each side the stalk, and sit close to it, like the grains of the flat Barley; the sheaths between the flowers are not so long as those of the other sorts, and form a kind of scaly covering to them. The flowers are of a pale red colour without, but the three lower segments are yellow within toward their base, with a few red stripes. The flowers do not all open at the same time, but the lower ones decay before those on the upper part of the spike are in beauty; however, they make a good appearance at a season when all flowers are valuable.

This sort propagates by offsets very fast; these should be planted in a warm border of kitchen-garden earth, and in winter they should be covered with glasses or mats to guard them from frost; for I have with a slight shelter preserved those which were in pots under a common frame, and some which were planted in the full ground, when the frost has not been severe; and I have always found that those plants which were hardily treated, grew much stronger than those which were placed in a moderate degree of warmth; so that where there is a convenience of covering a warm border with glasses in the winter, if

these roots are planted in the full ground, where they may be protected from the frost, there will be a greater probability of their flowering, than in any other method of culture.

The fifth sort grows naturally at the Cape of Good Hope, from whence I received the seeds, which succeeded in the Chelsea garden, where the plants annually produce their beautiful flowers.

This hath a round, smooth, bulbous root, which is covered with a thin dark-coloured skin, from which come out in autumn two or three very narrow grassy leaves, folded over each other at their base, but open flat above, and rise near two feet high. In the spring of the year arises a single stalk from between the leaves about two feet long, which always bend on one side; toward the upper part of this come out two or three flowers, ranged on one side of the stalk, standing upright, each having a narrow spatha, or hood, and long slender tubes, which swell large upward, and are divided into six parts, which are nearly equal. The flower is of a dusky flesh colour, and each segment of the petal has a rhomboidal mark of a dark red, or purple colour; afterward the tube of the flower opens, and the deep division of the petals is seen, and the three stamina with their summits appear, attended by the style with its trifid stigma, arising from the germen. This plant flowers in May and the beginning of June; as this plant is a native of a warm country, it requires protection from the frost in winter; therefore the bulbs should be planted in pots filled with light earth, and placed in the green-house in winter; or, where there is not such convenience, they may be put under a hot-bed frame during that season, where they may have air in mild weather, and be screened from the frost; in such situations I have had them thrive and flower very well.

This is propagated by offsets from the root in the same manner as the last, and also by seeds, which are frequently perfected in England; these should be sown the latter end of August, in pots filled with light earth, and placed in a shady situation till the middle of September; then the pots should be removed where they may have the sun great part of the day, and in October they must be placed under a hot-bed frame, where they may be protected from frost and great rains, but enjoy the free air in mild weather. In the spring the young plants will appear, when they will require a little water once in eight or ten days; but it should be given them sparingly, for too much wet will rot these tender bulbs. In May, when the danger of frost is over, the pots should be removed to a sheltered situation, where they may have the morning sun till noon; and, if the season proves dry, they must be now and then refreshed with water. Toward the latter end of June, the leaves of these plants will decay; then the roots should be taken up, and may be mixed with sand, and kept in a dry room till the end of August, when they should be planted again; and as the roots are small, four or five may be planted in each half-penny pot, filled with light earth; these should be placed where they may have only the forenoon sun, till the middle of September, when they should have a warmer situation; and in October they must be placed under a hot-bed frame as before, and treated in the same way during the winter season; and in the spring they must be placed in the open air till their leaves decay, when they may be again taken out of the ground, and treated in the same manner as before; but as the roots will have grown to a larger size, so when they are planted again, they should each have a separate half-penny pot, because now they will be large enough to flower, so may be treated as the old roots.

The sixth sort is also a native of the Cape of Good Hope, from whence I have several times received the seeds; the root of this sort is oval, not compressed as those of the common sorts. The leaves are very long and narrow, having two deep furrows running the whole length, the midrib rising very prominent, so as

to have the appearance of a four-cornered leaf. The leaves are single, and wrapped close about the flower-stalk at their base to a considerable length; there are seldom more than two of these leaves from one root; the stalk is slender and round, and rises about two feet high; and the top is garnished with two flowers, which are placed two inches and a half asunder on the same side of the stalk, each having a short spatha, or sheath, embracing the germen and the base of the tube, which is long, narrow, and recurved, but enlarges greatly before it is divided. The upper part of the flower is cut into six equal segments, which end in acute points of a purplish colour, which form a stripe through the middle of each segment. The petal is of a cream colour, and fades to a sulphur colour before it decays. This flowers in June, and sometimes the seeds ripen well in England. This may be propagated by offsets from the root, or by seeds in the same manner as the fifth sort, and the plants require the same treatment.

GLANDIFEROUS trees, are such trees as bear mast, as Acorns, &c.

GLANDULOUS roots, are such roots as grow kernel-wise.

GLANS is that sort of fruit which is contained within a smooth, but hard bark, having but one seed; its hinder parts covered with a kind of cup, the forepart being bare, as Acorns; but it is properly the fruit without the cup.

GLASTENBURY THORN. See **MESPILUS**.

GLAUCIUM. See **CHELIDONIUM**.

GLAUX, Sea Chickweed, or Milkwort, and black Saltwort, is a low trailing perennial plant, with leaves somewhat like Chickweed, but of a thicker consistence, which sit close to the stalks. The flowers come out from the bosom of the leaves; they are white, and like those of Chickweed. This is seldom cultivated in gardens, so I shall not trouble the reader with a further account of it. This grows upon the sea-shores in most parts of England.

GLECHOMA. Ground Ivy, Gill go by the Ground, Ale-hoof, or Turn-hoof.

This plant grows naturally under hedges, and upon the sides of banks in most parts of England, so is rarely cultivated in gardens, for which reason I shall pass over it, with barely mentioning it here.

GLEDITSIA. Lin. Gen. Plant. 1025. *Acacia*. Raii Meth. 161. Honey Locust, or three-thorned *Acacia*.

The **CHARACTERS** are,

It hath male and hermaphrodite flowers in the same katkin, and female flowers in different plants. The male katkins are long, compact, and cylindrical, and have each a three-leaved small empalement; they have three roundish petals, which spread open in form of a cup; these have a turbinate nectarium, whose mouth afterward grows to the parts of fructification; they have six slender stamina, which are longer than the petals, terminated by oblong compressed summits. The hermaphrodite flowers in the same katkin, are situated at the end; these have empalements, petals, and stamina like the male, and have a germen, style, and seeds like the female, which are situated on different trees, and are disposed in a loose katkin; these have a five-leaved empalement, and have five oblong petals, with two short thread-like nectariums, and a broad germen longer than the petals, supporting a short reflexed style, crowned by a thick stigma. The germen afterward becomes a large flat pod, with several transverse partitions, having a pulp in each division, surrounding one hard roundish seed.

This genus of plants is ranged in the second section of Linnæus's twenty-third class, intitled Polygamia Diœceia, which includes those plants which have male and hermaphrodite flowers in the same plant, and female flowers in different plants.

The **SPECIES** are,

1. **GLEDITSIA** (*Triacanthus*) spinis triplicibus axillaribus. Lin. Sp. 1509. *Gleditsia* with three thorns on the side of the branches. *Acacia Americana* Abruzæ folio triacanthos, five ad axillas foliorum, spinâ triplici donatâ. Pluk. Mant. 1. *Three-thorned American Acacia*.

2. **GLEDITSIA** (*Inermis*) spinis paucioribus, folis bipinnatis, filiquis ovalibus. *Gleditsia* with fewer spines, winged leaves, and oval pods. *Acacia Abruzæ* folio triacanthos, capsulâ ovali unicum semen claudente. Catesb. Car. 1. p. 43. *Three-thorned Acacia* with an *Abrus* leaf, and an oval pod containing one seed.

These trees grow naturally in America; the first sort is very common in most parts of North America, where it is known by the title of Honey Locust; this has been many years cultivated in the English gardens, and is known among the gardeners by the title of three-thorned *Acacia*. It rises with an erect trunk to the height of thirty or forty feet, and is armed with long spines, which have two or three smaller coming out from the side, and are frequently produced in clusters at the knots on the stems of the trees; they are sometimes three or four inches long. The branches of this tree are also armed with the same sort of spines, and are garnished with winged leaves, composed of ten pair of small leaves which sit close to the midrib, and are of a lucid green. The flowers come out from the side of the young branches in katkins; they are of an herbaceous colour, so make no figure. The hermaphrodite flowers are succeeded by pods near a foot and a half long, and two inches broad, divided into many cells by transverse partitions, each containing one smooth, hard, oblong seed, surrounded by a sweet pulp.

The leaves of this tree seldom come out till June in this country, and the flowers appear the latter end of July, but they do not flower till they are of a large size: there was one tree in the Chelsea garden which produced flowers several years, and there is one now growing in the Bishop of London's garden at Fulham, which produced pods in the year 1728, and came to their full size, but the seeds did not ripen.

The second sort hath much the appearance of the first, but it hath fewer spines. The leaves are smaller, and the pods are oval, containing but one seed; this was discovered by the late Mr. Catesby, in Carolina, from whence he sent the seeds to England, by the title of Water *Acacia*, by which it is known in the gardens.

These trees are propagated by seeds, which must be procured from America, where the trees grow naturally; those of the first sort are annually sent to England in plenty, by the title of Locust, or Honey Locust, to distinguish it from the false *Acacia*, which is frequently called Locust-tree in America; these seeds may be sown upon a bed of light earth in the spring, burying them half an inch deep; and if the spring should prove dry, they must be frequently watered, otherwise the plants will not come up the first year, for I have sometimes had the seeds remain two years in the ground before they have come up; therefore those who are desirous to save time, should sow the seeds as soon as they arrive, and plunge the pots into a moderate hot-bed, observing to water them frequently; by this method most of the plants will come up the same season, but these should be gradually inured to bear the open air, for if they are continued in the hot-bed, they will draw up weak; during the summer season, those plants in pots will require frequent waterings, but those in the full ground will not dry so fast, therefore need no water, unless the season should prove very dry. In autumn, those in the pots should be placed under a hot-bed frame to protect them from frost, for these young plants generally keep growing late in the summer, so the upper part of their shoots is tender, and the early frosts of the autumn often kill the ends of them, if they are not protected, and this frequently occasions great part of the shoots decaying in winter; for which reason those plants in the full ground should be covered with mats in autumn, on the first appearance of frost; for a small frost in autumn will do more mischief to these young shoots which are full of sap, than severe frost when the shoots are hardened.

The following spring the plants may be transplanted into nursery-beds, at a foot distance row from row, and

and six inches asunder in the rows; but this should not be performed till April, after the danger of hard frost is over; for as the plants do not put out their leaves till very late, so there will be no hazard in removing them any time before May. If the season should prove dry, they must be watered; and if the surface of the beds is covered with moss, or mulch, to prevent the earth from drying, it will be of great service to the plants. In these beds the plants may remain two years, during which time they must be constantly kept clean from weeds; and in the winter there should be some rotten tan, or other mulch, spread over the surface of the ground to keep out the frost. If the plants thrive well, they will be fit to transplant to the places where they are to remain after two years growth, for they do not bear removing when large; the best season for transplanting of these trees, is late in the spring; they thrive best in a light deep soil, for in strong shallow ground they become mossy, and never grow large; they should also have a sheltered situation, for when they are much exposed to winds, their branches are frequently broken in the summer season, when they are fully clothed with leaves.

GLOBULARIA. Lin. Gen. Plant. 106. Tourn. Inst. R. H. 466. tab. 265. *Blue Daisy*.

The CHARACTERS are,

It hath a flower composed of many florets, which are included in one common scaly empalement; each floret has an empalement of one leaf, which is tubulous, and cut into five segments at the top. The florets have one petal, whose base is tubulous, but the brim is cut into four parts; the upper segment, which is the least, is reflexed; they have four stamina the length of the petal, terminated by distinct summits; in the bottom of the tube is situated an oval germen supporting a single style, crowned by an obtuse stigma. The germen afterward becomes an oval seed, sitting in the common empalement.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetandria Monogynia, which includes those plants whose flowers have four stamina and one style.

The SPECIES are,

1. **GLOBULARIA** (*Vulgaris*) caule herbaceo, foliis radicalibus tridentatis, caulinis lanceolatis. Flor. Succ. 109. *Globularia with an herbaceous stalk, the lower leaves divided into three points, and those on the stalks spear-shaped. Globularia vulgaris. Tourn. 467. Common Globularia.*
2. **GLOBULARIA** (*Nudicaulis*) caule nudo, foliis integerrimis lanceolatis. Lin. Sp. Plant. 97. *Globularia with a naked stalk, and spear-shaped entire leaves. Globularia Pyrenaica, folio oblongo, caule nudo. Tourn. 467. Pyrenean Globularia, with an oblong leaf and naked stalk.*
3. **GLOBULARIA** (*Alypum*) caule fruticoso, foliis lanceolatis tridentatis integrisque. Prod. Leyd. 190. *Globularia with a shrubby stalk, spear-shaped leaves, some ending in three points, and others are entire. Globularia fruticosa, myrti folio tridentato. Tourn. 467. Shrubby Globularia with a trifid Myrtle leaf.*
4. **GLOBULARIA** (*Spinosa*) foliis radicalibus crenato-aculeatis, caulinis integerrimis mucronatis. Lin. Sp. Plant. 96. *Globularia with lower leaves crenated and prickly, those on the stalks entire, ending in a point. Globularia spinosa. Tourn. 467. Prickly Globularia.*
5. **GLOBULARIA** (*Cordifolia*) caule subnudo, foliis cuneiformibus tricuspидatis, intermedio minimo. Lin. Sp. Plant. 96. *Globularia with a naked stalk, and wedge-shaped leaves ending in three points, whose middle segment is the least. Globularia Alpina minima, origani folio. Tourn. 467. Smallest Alpine Globularia with a wild Marjoram leaf.*
6. **GLOBULARIA** (*Orientalis*) caule subnudo, capitulis alternis sessilibus, foliis lanceolato-ovatis integris. Lin. Sp. Plant. 97. *Globularia with a naked stalk, alternate beads sitting close to the stalks, and oval, spear-shaped, entire leaves. Globularia Orientalis, floribus per caulem sparsis. Tourn. Cor. 35. Eastern Globularia with flowers scattered along the stalks.*

The first of these plants grows plentifully about Montpellier, as also at the foot of the mountains Jura and Saleva, and in many other parts of Italy, and in Germany; this plant hath leaves very like those of the Daisy, but are thicker and smoother. The flower-stalks rise about six inches high, supporting a globular head of flowers, composed of several florets, which are included in one common scaly empalement; they are of a fine blue colour, and appear in June; these are succeeded by seeds, which sit in the empalement, and ripen in autumn.

The second sort grows plentifully in the woods, near the convent of the Carthusians, and on the Pyrenean mountains; this is much larger than the former, and hath a shrubby stalk a foot and a half high; the foot-stalk is quite naked. The leaves are narrower, and much longer.

The first sort may be propagated by parting of the roots after the manner of Daisies. The best season for parting and transplanting of the plants is in September, that they may take new root before the frosty weather comes on. They should be planted in a shady situation, and require a moist loamy soil, in which they will thrive much better than in a light ground and an open situation; but the plants should not be removed oftener than every other year, if they are required to flower strong.

The third sort grows about Montpellier in France, and in Valentia, and several other parts of Spain. This has a hard woody stem, which rises about two feet high, having many woody branches, beset with leaves like those of the Myrtle-tree. On the top of the branches the flowers are produced, which are of a blue colour, and globe-shaped; this plant may be propagated by cuttings, which should be cut off in April, just before they begin to make new shoots; the cuttings should be planted into pots filled with light fresh earth, and then placed into a very moderate hot-bed, observing to water and shade them until they have taken root, when they may be taken out of the bed, and inured to bear the open air by degrees. In summer these plants may be exposed with other hardy exotic plants, and in winter they should be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but should be screened from hard frost, which will destroy them, if they are exposed thereto, but in mild winters they will live in the open air. This plant never produces good seeds in this country.

The fourth sort was found in the mountains of Granada, by Dr. Albinus; this plant is of low growth, and may be propagated as the first; as may also the fifth sort, which is the least of all the sorts, and the most hardy; therefore should have a shady situation, and a cool moist soil.

The sixth sort was found by Dr. Tournefort in the Levant; this is somewhat tender, and should be sheltered from the frost in winter, under a frame, but in summer it should be exposed with other hardy exotic plants, and will require to be frequently watered in dry weather. This may be propagated by seeds, or by parting of their roots, as was directed for the first sort.

GLORIOSA. Lin. Gen. Plant. 374. Methonica. Tourn. Acad. R. Scien. 1706. *The Superb Lily*.

The CHARACTERS are,

The flower hath no empalement; it hath six long spear-shaped petals, which are waved, and reflexed to the foot-stalk. It hath six stamina, which spread open each way, and are terminated by prostrate summits. In the center is situated a globular germen, supporting a slender inclining style, crowned by an obtuse triple stigma. The germen afterward becomes an oval thin capsule having three cells, filled with globular seeds, disposed in a double range.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, which includes the plants whose flowers have six stamina and one style.

1. **GLORIOSA** (*Superba*) foliis longioribus capreolis terminalibus. *Superb Lily with longer leaves ending with clasps.*

claspers. Methonica Malabarorum. Hort. Lugd. 688. *Methonica of Malabar*, and the *Lilium Zeylanicum superbum*. Hort. Amst. 1. p. 69. *Superb Lily of Ceylon*.

2. GLORIOSA (*Cerulea*) foliis ovato-lanceolatis acutis. *Superb Lily with oval, spear-shaped, acute leaves*.

The first sort grows naturally on the coast of Malabar, and also in Ceylon, from whence it was first brought to the gardens in Holland, where it has been many years cultivated; this hath a long fleshy root of a whitish colour, and a nauseous bitter taste, from the middle of which arises a round weak stalk, which requires support to prevent its trailing on the ground. The stalks grow to the height of eight or ten feet, garnished with leaves placed alternate on every side, which are smooth, about eight inches long, and one inch and a half broad at the base, growing narrower till within two inches of the end, which runs out in a narrow point, ending with a tendril, or clasper, by which it fastens to the neighbouring plants for support. At the upper part of the stalk the flower is produced from the side, standing upon a slender foot-stalk; it is composed of six oblong petals, ending with acute points, which, on their first opening, are of an herbaceous colour, and spread wide open; the flower hanging downward as the Crown Imperial and Fritillary, but afterward the petals turn quite back, and change to a beautiful red flame colour, their acute points meeting at the top; these petals are finely waved on their edges. The six stamina spread out every way almost horizontal, and are terminated by prostrate summits. In the center of the flower is situated a roundish germen, supporting an inclining style, crowned by a triple stigma. This plant flowers in June and July, but seldom perfects seeds in this country. The stalks decay in autumn, and the roots remain inactive all the winter, and the new stalks come out in March. The roots and every part of this plant is very poisonous, so should not be put in the way of children.

The seeds of the second sort were sent me by Mons. Richard, gardener to the French king at Trianon; these were brought from Senegal by Mons. Adanson, who discovered this plant growing there naturally; this is said to have a blue flower, but the plants which are in the Chelsea garden have not yet flowered. This hath a climbing stalk, which is garnished with smooth leaves about three inches long, and two broad, ending in acute points, but have no tendril or clasper. The stalks as yet have not grown more than two feet high here, but have the appearance of climbing like the other sort. The leaves have a strong disagreeable scent on being handled, so as to be troublesome to the head if too near, or long smelt to.

As these plants rarely produce seeds in this country, they are generally propagated by their roots; those of the first sort creep and multiply pretty fast, but the second hath not as yet put out any offsets; but as the plants are young, we cannot as yet say how they may increase when they are of a proper age. These roots may be taken out of the ground when their stalks are decayed, and preserved in sand during the winter season, but they must be kept in the stove, or a warm room, where they can receive no injury from the cold; and in the spring they must be planted in pots filled with light earth, and plunged into the tan-bed in the stove; but others chuse to let the roots continue in the ground all the winter, keeping the pots always in the tan-bed: where this is practised, the roots should have very little water in the winter; for as they are then in an inactive state, so moisture at that time frequently rots the roots.

Toward the latter end of March, or the beginning of April, their stalks will appear, when there should be some tall sticks put down by them to support them, otherwise they will trail over the neighbouring plants, and the first sort will fasten to the plants by the tendrils, which are at the end of the leaves. The stalks of this sort will rise ten or twelve feet high, if the

roots are strong, and some of the stalks will produce two or three flowers, which come out from the wings of the stalk near the top; these flowers make a fine appearance in the stove, during their continuance, which is seldom more than ten days or a fortnight. In summer, when the plants are growing, they will require frequently to be watered, but they must not have it in too large quantities, for they are very subject to rot with much wet at any season. Those roots which are not taken out of the pots in winter, should be transplanted and parted the beginning of March, before they put out new fibres, or stalks, for they must not be removed when they are in a growing state; the pots in which these roots are planted should not be too large; for unless they are confined, they will not put out strong stalks; the largest roots may be planted in twopenny pots, but the small ones will require only pots of about five or six inches over at the top.

GLYCINE. Lin. Gen. Plant. 797. Apios. Boer. Ind. alt. *Knobbed-rooted Liquorice Vetch*.

The CHARACTERS are,

The empalement of the flower is of one leaf, divided into two lips at the top, the upper lip being obtuse and indented; the lower lip is longer, trifid, and acute, the middle indenture being extended beyond the other. The flower is of the butterfly kind. The standard is heart-shaped, deflexed on the sides, gibbous on the back, and indented at the point. The wings are small, oblong, and oval toward their end, and bend backward. The keel is narrow, sickle-shaped, turning upward with its point to the standard, where it is broadest. It hath ten stamina, nine of which are joined in one body, and the other stands single, terminated by single summits. In the center is situated an oblong germen supporting a spiral cylindrical style, crowned by an obtuse stigma. The germen afterward becomes an oblong pod with two cells, inclosing kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes the plants whose flowers have ten stamina joined in two bodies. Tournefort places the first sort under this genus of Astragalus; which is ranged in the fifth section of his tenth class, which includes the herbs with a butterfly flower, whose pointal turns to a pod with two cells.

The SPECIES are,

1. GLYCINE (*Apios*) foliis impari-pinnatis ovato-lanceolatis. Hort. Upsal. 227. *Glycine with oval, spear-shaped, winged leaves*. Astragalus tuberosus scandens, Fraxini folio. Tourn. Inst. 415. *Climbing tuberous Milk Vetch with an Ash leaf*; and the Apios Americana. Cornut. 200.
2. GLYCINE (*Frutescens*) foliis impari-pinnatis caule perenni. Hort. Cliff. 361. *Glycine with winged leaves and a perennial stalk*. Phaseoloides frutescens, Caroliniana, foliis pinnatis, floribus cæruleis conglomeratis. Hort. Angl. tab. 15. *Carolina Kidney-bean-tree, with winged leaves, and blue flowers growing in whorls*.
3. GLYCINE (*Abrus*) foliis abrupto-pinnatis pinnis numerosis obtusis. Lin. Sp. 1025. *Glycine with abrupt winged leaves, whose lobes are obtuse*. Orobus Americanus, fructu coccineo nigra maculâ notato. Tourn. Inst. 393. *American Bitter Vetch with a scarlet fruit, marked with a black spot, commonly called wild Liquorice in the West-Indies*.
4. GLYCINE (*Comosa*) foliis ternatis hirsutis, racemis lateralibus. Lin. Sp. Plant. 754. *Glycine with hairy trifoliate leaves, and flowers growing in long bunches from the sides of the stalks*. Phaseolus Marianus scandens, floribus commosis. Pet. Mus. 453. *Climbing Kidney-bean of Maryland with spiked flowers*.
5. GLYCINE (*Tomentosa*) foliis ternatis tomentosis, racemis axillaribus brevissimis, leguminibus dispermis. Lin. Sp. Plant. 754. *Glycine with woolly trifoliate leaves, and very short spikes of flowers proceeding from the sides of the stalks, with pods containing two seeds*. Anonis phaseoloides scandens, floribus flavis sessilibus. Hort. Elth. 30. tab. 26. *Climbing Rest-Harrow like Kidney-bean, with yellow flowers sitting close to the stalks*.

The first sort grows naturally in Virginia; this hath roots composed of several knobs, or tubers, which hang to each other by small strings; from these come out in the spring slender twining stalks, which rise to the height of eight or ten feet, garnished with winged leaves, composed of three pair of oval spear-shaped lobes, terminated by an odd one. The flowers come out in short spikes from the side of the stalks; they are of a Pea-blossom kind, of a dirty flesh-colour, having little scent. These appear in August, but do not produce seeds in England. The stalks decay in autumn, but the roots continue; this is propagated by parting of the roots, each of the tubers being separated from the principal root, will grow; the best time for this is about the end of March, or the beginning of April, before they put out shoots. The roots should be planted in a warm situation, and in hard frost covered with tan or mulch to protect them, otherwise they will not live abroad in this country: where they have been planted against a south wall, they have thriven and flowered extremely well, which they seldom do in any other situation; and those roots which are planted in pots rarely flower, nor do their stalks rise near so high as those which are planted in the full ground; some ignorant persons call this the Twickenham Climber.

The second sort was brought from Carolina, but has been since observed in Virginia, and some other places in North America; this sort has woody stalks, which twist themselves together, and also twine round any trees that grow near, and will rise to the height of fifteen feet, or more. The leaves are winged, and in shape somewhat like the Ash-tree, but have a greater number of pinnæ. The flowers are produced in clusters from the wings of the leaves, which are of a purple colour; these are succeeded by long cylindrical pods, shaped like those of the scarlet Kidney-bean, containing several kidney-shaped seeds, but these are never perfected in England.

This climbing shrub is propagated in several nurseries near London, where it is known by the name of Carolina Kidney-bean-tree. It is increased by laying down the young branches in October, which will be rooted well by that time twelvemonth (especially if they are duly watered in dry weather) and may then be transplanted, either in a nursery for a year to get strength, or to the place where they are to remain for good, which should be in a warm light soil and a sheltered situation, where they will endure the cold of our ordinary winters very well; and if their roots are covered with straw, Fern, Peas-haulm, or any other light covering, there will be no danger of their being destroyed by the frost.

The third sort grows naturally in both Indies, and also in Egypt. This is a perennial plant, with slender twining stalks, which twist about any neighbouring support, and rise to the height of eight or ten feet, garnished with winged leaves, composed of sixteen pair of small, oblong, blunt lobes, set close together; these have the taste of Liquorice, from whence the inhabitants of the West-Indies have given it the name of Wild Liquorice, and use the herb for the same purpose as the Liquorice in Europe. The flowers are produced from the side of the stalks in short spikes or bunches; they are of a pale purple colour, and shaped like those of the Kidney-bean; these are succeeded by short pods, each containing three or four hard round seeds of a scarlet colour, with a black spot or eye on that side which is fastened to the pod. The seeds of this plant are frequently strung, and are worn as ornaments by the natives of those countries, where the plants grow naturally: they are frequently brought to England from the West-Indies, and are wrought into various forms, with shells and other hard seeds.

This plant is propagated by seeds, which must be sown upon a good hot-bed in the spring; but as the seeds are very hard, so unless they are soaked in water twelve or fourteen hours before they are sown, they frequently lie in the ground a whole year before they

vegetate; but when soaked, the plants will appear in a fortnight after the seeds are sown, if they are good, and the bed in a proper temperature of heat. When the plants are two inches high, they should be each transplanted into a separate pot, filled with light earth, and plunged into a hot-bed of tanners bark, where they should be shaded from the sun till they have taken new root; after which they must be treated in the same manner as other tender plants from the same countries, always keeping them in the bark-stove, for they are too tender to thrive in any other situation in England. This sort will flower the second year from seeds, and sometimes ripens seeds here.

There are two other varieties of this plant, one with a white, and the other a yellow seed, but the plants do not differ from the other in leaf or stalk; but as these have not as yet flowered in England, I do not know how their flowers may differ.

The fourth sort hath a perennial root and an annual stalk, which decays in the autumn. This rises from two to three feet high, with slender herbaceous stalks, which are garnished with trifoliate hairy leaves, sitting close to the stalks; the small leaves or lobes, are of the oval spear-shape, ending in acute points. The flowers come out from the side of the stalks; at the foot-stalk of the leaves; the naked part of the foot-stalk is about two inches long, and the spike of flowers is about the same length, and is recurved; the flowers are of a Pea-blossom kind, sitting close together. They are small, and of a fine blue colour, coming out the beginning of June, and are sometimes succeeded by seeds in England, which ripen in August.

This sort grows naturally in North America, and is hardly enough to live in the open air in England. It may be propagated by seeds, or parting of the roots; the former is the best method, where good seeds can be obtained: these may be sown on a bed of light earth in the spring, and if the season should prove dry, they must be frequently refreshed with water, otherwise they will remain a long time in the ground before they vegetate: when the plants come up, they must be kept clean from weeds in the summer, and in the autumn when their stalks are decayed, if some rotten tanners bark is spread over the surface of the ground, it will protect the roots from being injured by the frost. In the spring, the roots should be transplanted to the places where they are designed to remain, which must be in a warm sheltered situation, but not too much exposed to the sun, and in a light soil, where they will thrive and produce flowers annually. If this is propagated by parting of the roots, it should be done in the spring, before the roots begin to shoot, which is the best season for transplanting the plants: but these roots should not be parted oftener than every third year, for if they are often removed they will not flower so strong.

The fifth sort hath a perennial root and a climbing stalk, which rises near four feet high, garnished with woolly trifoliate leaves: the flowers come out in short bunches from the side of the stalks; they are small, of a yellow colour, and are succeeded by short pods, which contain two roundish seeds in each. This flowers in June, and the seeds ripen in autumn. It grows naturally in America, but is too tender to live in the open air in England. This is propagated in the same manner, and requires the same treatment as the third sort.

GLYCYRRHIZA. Lin. Gen. Plant. 788. Tourn. Inst. R. H. 389. tab. 210. [so called of γλυκύς, sweet, and ῥίζα, Gr. a root, q. d. sweet root: the ancients called it Scythian Root, because the Scythians first brought it into use.] Liquorice; in French, *Reglisse*.

The CHARACTERS are,

The flower hath a permanent tubulous empalement of one leaf, divided into two lips; the upper lip is cut into three parts, the middle one being broad and bifid, the under lip is single. The flower hath four petals, is of the butterfly kind, having a long erect standard, with oblong

oblong wings, and a two-leaved keel which is acute. It hath ten stamina, nine joined and one standing single; they are longer than the keel, and terminated by roundish summits. In the bottom is situated a short germen, supporting an aryl-shaped style the length of the stamina, crowned by a rising obtuse stigma. The germen afterward becomes an oblong, or oval compressed pod with one cell, including two or three kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, which includes those plants which have ten stamina joined in two bodies.

The SPECIES are,

1. GLYCRRHIZA (*Glabra*) leguminibus glabris. Hort. Cliff. 490. *Liquorice with smooth pods. Glycyrrhiza siliquosa, vel Germanica. C. B. P. Common Liquorice.*
2. GLYCRRHIZA (*Echinata*) leguminibusechinatis. Prod. Leyd. 386. *Liquorice with prickly pods. Glycyrrhiza capite echinato. C. B. P. Rough-podded Liquorice.*
3. GLYCRRHIZA (*Hirsuta*) leguminibus hirsutis. Prod. Leyd. 386. *Liquorice with hairy pods. Glycyrrhiza Orientalis, siliquis hirsutissimis. Tourn. Cor. Eastern Liquorice with hairy pods.*

The first sort is that which is commonly cultivated in England for medicine; the other two kinds are preserved in curious botanic gardens for variety, but their roots are not so full of juice as the first, nor is the juice so sweet; though the second sort seems to be that which Dioscorides has described and recommended, but I suppose the goodness of the first has occasioned its being so generally cultivated in Europe. The roots of this run very deep into the ground, and creep to a considerable distance, especially where they are permitted to stand long unremoved; from these arise strong herbaceous stalks, four or five feet high, garnished with winged leaves, composed of four or five pair of oval lobes, terminated by an odd one; the leaves and stalks are clammy, and of a dark green; the flowers come out in spikes from the wings of the stalks, standing erect; they are of a pale blue colour, and are succeeded by short compressed pods, each containing two or three kidney-shaped seeds. It flowers the latter end of July, but the seeds do not ripen in England.

This plant delights in a light sandy soil, which should be three feet deep at least, for the goodness of Liquorice consists in the length of the roots: the greatest quantity of Liquorice which is propagated in England, is about Pontefract in Yorkshire, and Godalmin in Surry; though of late years there hath been a great deal cultivated in the gardens near London: the ground in which you intend to plant Liquorice, should be well dug and dunged the year before you plant it, that the dung may be perfectly rotted, and mixed with the earth, otherwise it will be apt to stop the roots from running down; and before you plant it, the ground should be dug three spades deep, and laid very light; when your ground is thus well prepared, you should furnish yourself with fresh plants taken from the sides or heads of the old roots, observing that they have a good bud or eye, otherwise they are subject to miscarry; these plants should be about ten inches long, and perfectly sound.

The best season for planting them is in the beginning or middle of March, which must be done in the following manner, viz. First strain a line cross the ground in which you would plant them, then with a long dibble made on purpose, put in the shoot, so that the whole plant may be set strait into the ground, with the head about an inch under the surface in a strait line, about a foot asunder, or more, in the rows, and two feet distance row from row; and after having finished the whole spot of ground, you may sow a thin crop of Onions, which being plants that do not root deep into the ground, nor spread much above, will do the Liquorice no damage the first year; for the Liquorice will not shoot very high the first season, and the hoeing of the Onions will also keep the ground clear from weeds; but in doing of this you must be careful not to cut off the top shoots

the Liquorice plants when they appear above ground; which would greatly injure them; and also observe to cut up all the Onions which grow near the heads of the Liquorice; and after your Onions are pulled up, you should carefully hoe and clean the ground from weeds; and in October, when the shoots of the Liquorice are decayed, you should spread a little very rotten dung upon the surface of the ground, which will prevent the weeds from growing during the winter, and the rain will wash the virtue of the dung into the ground, which will greatly improve the plants.

In the beginning of March following you should slightly dig the ground between the rows of Liquorice, burying the remaining part of the dung; but in doing of this, you should be very careful not to cut the roots. This stirring of the ground will not only preserve it clean from weeds a long time, but also greatly strengthen the plants.

The distance which I have allowed for planting these plants, will, I doubt not, by some, be thought too great; but in answer to that, I would only observe, that as the largeness of the roots is the chief advantage to the planter, so the only method to obtain this, is by giving them room; and besides, this will give a greater liberty to stir and dress the ground, which is of great service to Liquorice; and if the plantation designed were to be of an extraordinary bigness, I would advise the rows to be made at least three feet distant, whereby it will be easy to stir the ground with a breast plough, which will greatly lessen the expence of labour.

These plants should remain three years from the time of planting, when they will be fit to take up for use, which should not be done until the stalks are perfectly decayed; for when it is taken up too soon, it is subject to shrink greatly, and lose of its weight.

The ground near London being rich, increases the bulk of the root very fast; but when it is taken up, it appears of a very dark colour, and not near so slightly as that which grows upon a sandy soil in an open country.

The second sort grows naturally in some parts of Italy, and in the Levant; the stalks and leaves of this are very like those of the first, but the flowers are produced in shorter spikes, and the pods which succeed them are very short, broad at their base, ending in acute points, and are armed with sharp prickles. This flowers about the same time as the first, and in warm seasons will perfect seeds in England.

The third sort grows naturally in the Levant, from whence the seeds were sent to the royal garden at Paris, by Dr. Tournefort. This hath much the appearance of the other two species, but the pods of it are hairy, and longer than those of the other. Both these sorts may be propagated in the same manner as the first, or from seeds, which may be sown in the spring on a bed of light earth; but as neither of these are used, so they are seldom propagated unless for the sake of variety.

GNAPHALIMUM. Lin. Gen. Plant. 850. Elichrysium. Tourn. Inst. R. H. 452. tab. 259. Goldylocks, or Eternal Flower; in French, *Immortelle*.

The CHARACTERS are,

It hath a compound flower, made up of hermaphrodite florets and female half florets, included in one scaly empalement; the hermaphrodite florets are tubulous, funnel-shaped, and cut into five parts at the brim, which are reflexed; these have five short hairy stamina, terminated by cylindrical summits. In the center is situated a germen, supporting a slender style the length of the stamina, crowned by a bifid stigma; the germen afterward becomes a single seed, which in some species is crowned with a hairy down, and in others a feathery down. The female flowers which are intermixed with these have no stamina, but a germen supporting a slender style, crowned by a bifid reflexed stigma. These are in some species fruitful, and in others they are barren. The empalement of the flower is permanent and shining.

This

This genus of plants is ranged in the first section of Linnæus's nineteenth class, which includes those plants which have hermaphrodite and female flowers inclosed in one common empalement, and are fruitful.

The SPECIES are,

1. GNAPHALIUM (*Stæchas*) fruticosum foliis linearibus, ramis virgatis, corymbo composito. Hort. Cliff. 401. *Goldyllocks with a shrubby stalk garnished with very narrow leaves, and a compound corymbus of flowers.* Elichrysum seu stæchas citrina angustifolia. C. B. P. 264. *Cassidony, or narrow-leaved Goldyllocks.*
2. GNAPHALIUM (*Angustissimum*) foliis linearibus, caule fruticoso ramoso, corymbo composito. Hort. Cliff. 401. *Goldyllocks with a branching shrubby stalk, and very narrow leaves, with a compound corymbus of flowers.* Elichrysum angustissimum folio. Tourn. Inst. R. H. 452. *Goldyllocks with very narrow leaves.*
3. GNAPHALIUM (*Uniflorum*) foliis alternis, acutè dentatis, subtus villosis, pedunculis longissimis unifloris. *Goldyllocks with alternate leaves sharply indented, woolly on their under side, with very long foot-stalks sustaining one flower.* Elichrysum sylvestre latifolium, flore parvo singulari. Tourn. Inst. R. H. 452. *Broad-leaved wild Goldyllocks, with a single small flower.*
4. GNAPHALIUM (*Luteo-album*) foliis semiamplexicaulibus ensiformibus, repandis obtusis, utrinque pubescentibus, floribus conglomeratis. Prod. Leyd. 149. *Goldyllocks with sword-shaped leaves half embracing the stalks, which are obtuse, reflexed, woolly on both sides, and flowers growing in clusters.* Elichrysum sylvestre latifolium capitulis conglobatis. C. B. P. 264. *Broad-leaved wild Goldyllocks, with heads growing in clusters.*
5. GNAPHALIUM (*Aquaticum*) caule ramoso diffuso, floribus confertis. Flor. Lapp. 300. *Goldyllocks with a diffused branching stalk, and flowers in clusters at the top.* Elichrysum aquaticum, ramosum, minus, capitulis, foliaceis. Tourn. Inst. 452. *Lesser branching aquatic Goldyllocks, with leafy heads.*
6. GNAPHALIUM (*Sylvaticum*) caule simplicissimo, floribus sparsis. Flor. Lapp. 298. *Goldyllocks with a single stalk, and flowers growing scatteringly.* Elichrysum spicatum. Tourn. Inst. R. H. 453. *Spiked Goldyllocks.*
7. GNAPHALIUM (*Dioicum*) caule simplicissimo corymbo simplici terminali, sarmentis procumbentibus. Hort. Cliff. 400. *Goldyllocks with a single stalk terminated by a single corymbus, and trailing branches.* Elichrysum montanum flore rotundiori candido. Tourn. Inst. R. H. 453. *Mountain Goldyllocks with a rounder white flower.*
8. GNAPHALIUM (*Montanum*) foliis radicalibus cuneiformibus, caulinis acutis sessilibus, caule simplicissimo, capitulo terminali aphylo, floribus oblongis. *Goldyllocks with the lower leaves wedge-shaped, those on the stalks acute, and sitting close, a single stalk without leaves, terminated by oblong flowers.* Elichrysum montanum longiore folio & flore albo. Tourn. Inst. 453. *Mountain Goldyllocks, with a longer leaf and white flower.*
9. GNAPHALIUM (*Chrysocomum*) humile, caule suffruticoso, foliis linearibus subtus argenteis, squamis calycinis longioribus acuminatis. *Low Goldyllocks with a shrubby stalk, very narrow leaves, silvery on their under side, and longer acute-pointed scales to the empalement.* Chamæchrysocoma prælongis purpurascensibusque Jacææ capitulis. Barrel. Icon. 406. *Dwarf Goldyllocks with longer and purplish heads like Knapweed.*
10. GNAPHALIUM (*Orientele*) subherbaceum, foliis lineari-lanceolatis sessilibus, corymbo composito, pedunculis elongatis. Lin. Sp. 195. *Herbaceous Goldyllocks with narrow spear-shaped leaves, and a compound cluster of flowers.* Elichrysum Orientale. C. B. P. 264. *Eastern Goldyllocks, called Immortal Flower.*
11. GNAPHALIUM (*Ignescens*) fruticosum, foliis sublan- ceolatis tomentosis sessilibus, corymbis alternis con- globatis, floribus globosis. Prod. Leyd. 149. *Shrubby Goldyllocks, with spear-shaped woolly leaves sitting close to the stalks, and alternate clusters of globular flowers.* Eli- chrysum Germanicum, calyce ex aureo rutilante. Tourn. Inst. R. H. 452. *German Goldyllocks having a reddish gold-coloured empalement.*
12. GNAPHALIUM (*Margaritaceum*) herbaceum foliis li- neari-lanceolatis acuminatis, alternis, caule superne ramoso corymbis fastigiatis. Hort. Cliff. 401. *Herba- ceous Goldyllocks with narrow, spear-shaped, pointed leaves placed alternate, and the upper part of the stalk branching, with a compact corymbus of flowers.* Elichrysum Ame- ricanum latifolium. Tourn. Inst. R. H. 453. *Broad- leaved American Goldyllocks.*
13. GNAPHALIUM (*Fetidum*) herbaceum foliis amplexi- caulibus, integerrimis acutis subtus tomentosis, caule ramoso. Hort. Cliff. 402. Lin. Sp. Plant. 850. *Her- baceous Goldyllocks with entire leaves embracing the stalks, woolly on their under side, and a branching stalk.* Elichrysum Africanum foetidissimum, amplissimo folio. Tourn. Inst. R. H. 454. *Most stinking African Goldyllocks with a large leaf.*
14. GNAPHALIUM (*Argenteum*) foliis amplexicaulibus in- tegerrimis ovatis nervosis utrinque tomentosis, caule ramoso. Hort. Cliff. 402. *Goldyllocks with entire acute leaves embracing the stalks, woolly on both sides, and a branching stalk.* Elichrysum Africanum foetidissimum amplissimo folio calyce argenteo. Tourn. Inst. 454. *Most stinking African Goldyllocks, with a very large leaf, and a silvery empalement to the flower.*
15. GNAPHALIUM (*Undulatum*) herbaceum foliis decur- rentibus lanceolatis acutis, undatis, subtus tomentosis, caule ramoso. Hort. Cliff. 402. *Goldyllocks with acute running leaves which are waved, and woolly on their under side, and a branching stalk.* Elichrysum graveolens acutifolium, caule alato. Hort. Elth. 130. *Stinking Goldyllocks, with an acute leaf and winged stalk.*
16. GNAPHALIUM (*Cymosum*) herbaceum foliis lanceo- latis trinerviis supra glabris caule infernè ramoso ter- minali. Hort. Cliff. 401. *Goldyllocks with spear-shaped leaves, having three veins, smooth on their upper side, and the under branches terminated with flowers.* Elichrysum Africanum folio oblongo, subtus incano, supra viridi, flore luteo. Boerh. Ind. alt. 1. 121. *African Goldyllocks with an oblong leaf, hoary on the under side, and green above, with a yellow flower.*
17. GNAPHALIUM (*Americanum*) caule herbaceo simpli- cissimo, foliis lanceolatis obtusis tomentosis, floribus spicatis lateralibusque. *Goldyllocks with a single herba- ceous stalk, obtuse, spear-shaped, woolly leaves, and flowers growing in spikes from the sides of the stalks.* Gnaphalium ad stæchadem citrinam accedens. Sloan. Cat. Jam. 125. *Cudweed like golden Cassidony.*
18. GNAPHALIUM (*Rutilans*) herbaceum foliis lineari- lanceolatis, caule infernè ramoso, corymbo composito terminali. Hort. Cliff. 401. *Herbaceous Goldyllocks with narrow spear-shaped leaves, the under part of the stalk branching, and a compound corymbus terminating the branches.* Elichrysum Africanum, folio oblongo an- gusto, flore rubello postea aureo. Boerh. Ind. alt. 121. *African Goldyllocks with an oblong narrow leaf and a reddish flower, which is afterwards yellow.*
19. GNAPHALIUM (*Sanguineum*) herbaceum, foliis de- currentibus lanceolatis tomentosis planis apiculo nudo terminali. Amœn. Acad. 4. p. 78. *Herbaceous Goldyllocks, with spear-shaped, woolly, running leaves, terminated by a naked point.* Chrysocoma Syriaca, flore atro rubente. Breyn. Cent. 146.
20. GNAPHALIUM (*Fruticosum*) frutescens foliis infernè lanceolatis caulinis lineari-lanceolatis, utrinque tomen- tosis, corymbo composito terminali. *Shrubby Goldyllocks with the under leaves spear-shaped, those on the stalks narrow, spear-shaped, woolly on both sides, and the stalks terminated by a corymbus of flowers.* Elichrysum Af- ricanum frutescens, angustis & longioribus foliis in- canis. Hort. Amst. 2. p. 109. *Shrubby African Goldyl- locks, with longer and narrower leaves which are hoary.*
21. GNAPHALIUM (*Oderatissimum*) foliis decurrentibus obtusis infernè villosis, corymbis conglobatis termi- nalibus. *Goldyllocks with obtuse running leaves, hoary on their under side, and a clustered corymbus of flowers ter- minating the stalk.* Elichrysum foliis linearibus decur- rentibus, subtus incanis, floribus corymbosis. Fig. Plant. tab. 131. fol. 2. *Goldyllocks with narrow running leaves, hoary on their under side, and flowers growing in a corymbus.*
22. GNAPHALIUM (*Plantaginifolium*) sarmentis procum- bentibus caule simplicissimo, foliis radicalibus ovatis maximis,

maximis, sarmentis procumbentibus. Lin. Sp. Plant. 850. *Goldyllocks with a simple stalk, large oval leaves at bottom, and trailing runners.* Gnaphalium plantaginifolio, Virginianum. Pluk. Alm. 171. *Virginia Goldyllocks with a Plantain leaf.*

23. GNAPHALIUM (*Obtusifolium*) herbaceum foliis lanceolatis, caule tomentoso paniculato terminalibus glomeratis conicis. Lin. Sp. Plant. 851. *Goldyllocks with spear-shaped leaves, a woolly stalk, terminated by a conical cluster of flowers.* Elichrysum obtusifolium, capitulis argenteis conglobatis. Hort. Elth. 130. *Blunt-leaved Goldyllocks, with silvery beads growing in clusters.*

24. GNAPHALIUM (*Spicatum*) foliis lanceolatis decurrentibus tomentosis, floribus spicatis terminalibus lateralibusque. *Goldyllocks with spear-shaped, woolly, running leaves, and flowers growing in spikes at the ends and sides of the stalks.* Elichrysum caule alato, floribus spicatis. Sloan. Cat. Jani. 125. *Goldyllocks with a winged stalk and spiked flowers.*

The first sort hath a shrubby stalk, which rises about three feet high, branching out into long slender stalks irregularly; the lower branches are garnished with obtuse leaves, two inches and a half long, and an eighth of an inch broad at the point, but those upon the flower-stalks are very narrow, ending in acute points; the whole plant is very woolly: the flowers terminate the stalks in a compound corymbus; their empalements are of a silvery colour at first, and very neat, but afterward turn of a yellowish sulphur colour. If these are gathered before the flowers are much opened, the heads will continue in beauty many years, especially if they are kept from the air and dust. The plants begin to flower in June, and there is a succession of flowers all the summer, some of which will continue in beauty most part of the winter. This is generally supposed to be the true golden Cassidony of the shops, but the second sort is usually substituted for it in England.

It is propagated by slips or cuttings, which may be planted in June or July, in a bed of light earth, and covered with glasses, or shaded with mats, observing to refresh them frequently with water, but it must not be given in large quantities; these cuttings will put out roots in six or eight weeks, then they should be taken up and planted in pots filled with light earth, and placed in a shady situation till they have taken new root, when they may be removed to an open situation, and placed among other hardy exotics, till about the middle or end of October; at which time they should be placed under a common frame, where they may be protected from frost, but in mild weather they should be exposed to the open air. With this management in winter, the plants will be much stronger than those which are kept in the green-house, where they generally draw too weak; for this sort only wants to be sheltered from hard frost, being so hardy as in very mild winters to live abroad in warm borders near walls, with little shelter.

The second sort hath a shrubby stalk, which divides into many slender branches, covered with a white bark; these form a thick bushy under shrub, and rise near three feet, garnished with very narrow leaves, hoary on their under side, but green on their upper, placed without order on every side the stalks; the flowers are produced in a compound corymbus at the end of the branches; their heads are small, and are of a yellow colour when fully blown; these are continued in succession most part of summer. This grows naturally in France and Germany, and is hardy enough to live in the open air in England. It is propagated by slips or cuttings, which may be planted in a shady border during any of the summer months, and in the autumn they may be transplanted into the places where they are designed to remain. This should have a dry undunged soil, in which it is rarely injured unless in the most severe frost.

The third sort is an annual plant, which grows naturally in Italy and Sicily; this hath an herbaceous stalk, which rises little more than a foot high, garnished with acute indented leaves, which are hoary on

their under side; the flowers stand upon long foot-stalks, which rise far above the branches, each sustaining one small whitish flower. These appear in July, and the seeds ripen in September. It is propagated by seeds, which should be sown in autumn upon a bed of light earth, where the plants are designed to remain; and when the plants come up in the spring, they should be thinned where they are too close, and kept clean from weeds, which is all the culture they require.

The fourth sort is an annual plant with woolly leaves, which rise with woolly stalks about eight inches high, garnished with oblong leaves which embrace the stalks with their base; the flowers grow in close clusters at the top, and from the side of their stalks, which are included in dry silvery empalements.

There is another species of this with narrower leaves, not quite so woolly; the stalks rise higher, and are more branched; the flowers grow in close bunches on the top of the stalks, and are of a pale yellow colour. Both these sorts will come up better from the scattered seeds, than when they are sown by art; but if the seeds are sown, it must be soon after they are ripe, otherwise they will not succeed. The plants require no other care but to keep them clean from weeds, and thinned where they are too close. They flower in July, and the seeds ripen in autumn.

The fifth sort is an annual plant, which grows naturally in many parts of England, on places which are covered with water in the winter; this is a low branching plant, with silvery leaves and dark heads of flowers, but being of no use is not cultivated in gardens.

The sixth sort is also an annual plant with narrow leaves, which are hoary on their under side; the stalks grow erect about a foot high, and at every joint is produced a short spike of white flowers, with dark-coloured empalements. This is found growing naturally in some parts of England, so is not often admitted into gardens. If the seeds of this sort are permitted to scatter, the plants will come up in the spring with greater certainty than if sown, and they will require little culture. These flower in July, and the plants decay soon after they have ripened their seeds.

The seventh sort grows naturally in the northern parts of England, upon the tops of hills and mountains, where the shoots which are sent out from every side of the plant put out roots, whereby it is propagated in great plenty: the leaves of this grow close to the ground, they are narrow at their base, but rounded at the end where they are broad; they are near an inch long, and hoary on their under side; the stalks are single, and rise about four inches high, terminated by a corymbus of flowers which is single. This flowers in May and June.

There are two varieties of this, one with a purple and the other a variegated flower, which have risen accidentally from seeds, but continue their difference in the gardens. They are easily propagated by offsets, which should be planted in the autumn, in a shady situation, where they will require no other care but to keep them clean from weeds. This plant is called *Pes Cati*, or *Catsfoot*.

The eighth sort grows naturally on the Alps. This is a low plant, with under leaves like the last mentioned; the stalks are single, and rise about six inches high, garnished with very small acute leaves, and terminated by four or five oblong flowers, which in some plants are white, and in others of a purplish colour. They appear about the same time as the former sort, and the plants may be propagated and treated in the same manner.

The ninth sort grows naturally in Spain and Italy. This is a low plant with a ligneous stalk, which seldom rises more than six inches high, garnished with very narrow leaves, white on their under side; the flowers are produced from the side of the stalks, each standing upon a separate foot-stalk; their empalements are scaly and long, ending in acute stiff points, and are of a purplish colour. This sort flowers in July, but seldom perfects seeds in this country.

The tenth sort is supposed to have been brought first from India to Portugal, where it has been long propagated for the beauty of its golden heads of flowers, which, if gathered before they are too open, will continue in beauty several years; so that in the winter season they ornament their churches with these flowers, and many of them are annually brought to England, and sold for ornaments to the ladies. These plants have a short shrubby stalk, seldom rising more than three or four inches high, putting out many heads; the leaves are narrow and woolly on both sides, and come out without order; the flower-stalks arise from these heads; they grow eight or ten inches high, are garnished all the way with narrow hoary leaves, and terminated by a compound corymbus of bright yellow flowers with large heads. These begin to flower in May, and there is a succession of them most part of summer. This is propagated by slipping off the heads during any of the summer months, and after stripping off the lower leaves, they should be planted in a bed of light earth, covering them with hand-glasses, which must be shaded every day when the sun is warm; and the cuttings must be supplied with water, which should be often repeated, but not in too great quantities; when these are rooted they should be planted in pots, and treated in the same manner as hath been directed for the first sort. These plants in mild winters will live abroad in a very warm border with little shelter, and the hardier they are treated, the greater number of flowers they will produce; for when they are drawn weak in a green-house, they never flower so strong. The eleventh sort hath very woolly stalks and leaves, which are much longer than those of the tenth; the stalks rise a foot high, sending out a few side branches; these are terminated by a compound corymbus of flowers, whose heads are small, and of a gold colour, changing a little red as they fade. This is propagated by slips in the same manner as the last mentioned, but the plants will live in the open air, if they are planted on a dry soil.

The twelfth sort grows naturally in North America, but has been long in the English gardens. This hath a creeping root, which spreads far in the ground, so as to become a troublesome weed very often, unless it is kept within bounds; the stalks of this are woolly, rising a foot and a half high, garnished with long leaves ending in acute points, which are placed alternate, and are woolly on their under side; the upper part of the stalk branches into two or three divisions, each being terminated by a close corymbus of flowers, with pretty large silvery empalements, which, if gathered and properly dried, will retain their beauty several years. This sort will thrive in almost any soil or situation, and is easily propagated by its creeping roots. It flowers in June and July, and the stalks decay in autumn.

The thirteenth sort grows naturally at the Cape of Good Hope. This is an annual plant, which sends out many oblong blunt leaves near the root; the stalks rise a foot and a half high, garnished with leaves placed alternate, which are broad at their base where they embrace the stalks, but end in acute points; they are woolly, and when handled, emit a very rank odour; the stalks are terminated by a corymbus of flowers, in large silvery empalements, which will retain their beauty several years.

The fourteenth sort grows naturally at the Cape of Good Hope, and is an annual plant, very like the former sort, but the leaves are of a yellowish green on their upper side, and woolly on their under; the stalks branch, and the heads of flowers are of a bright yellow colour, and these differences are permanent. Both these plants are propagated by seeds, which, if sown in the autumn on a warm border, will more certainly succeed, than when they are sown in the spring; or if the seeds are permitted to scatter, the plants will come up without care, and may be transplanted while they are young, to the places where they are designed to remain: when the plants have taken root, they will require no other care but to keep them clean from

weeds. They flower in July, and the seeds ripen in autumn.

The fifteenth sort grows in Africa, and also in North America, from both these countries I have received the seeds. It is an annual plant, with oblong leaves at the bottom, which are a little waved, and hoary on their under side. The stalks rise about a foot high, and are garnished with acute-pointed leaves; from their base runs a border or wing along the stalk; the whole plant has a disagreeable odour. The flowers grow in a corymbus on the top of the stalks, they are white, and appear in July. The seeds ripen in the autumn, which, if permitted to scatter, the plants will come up without care, as the two former sorts.

The sixteenth sort rises with a shrubby stalk three or four feet high, sending out many branches from the lower part, garnished with narrow spear-shaped leaves, which half embrace the stalks with their base; they are of a dark green on their upper side, but are hoary on their under; the stalks are terminated by a compound corymbus of yellow flowers, whose heads are small: these continue in succession great part of the summer, but are rarely succeeded by seeds in England. It is easily propagated by cuttings in any of the summer months, which may be planted in a shady border, and duly watered. These will take root in a month or five weeks, and may then be taken up and planted in pots, placing them in a shady situation till they have taken fresh root; then they may be removed to a sheltered situation, and placed with other hardy green-house plants till autumn, when they must be carried into the green-house, where, during the winter season, they should have as much free air as possible in mild weather, for they only require protection from frost, so they should be treated in the same manner as other hardy green-house plants.

The seventeenth sort is an annual plant, which grows naturally in France, Italy, and Spain. This hath a woolly herbaceous stalk, which rises six or eight inches high, garnished with obtuse, spear-shaped, woolly leaves. The flowers are produced in short spikes from the side, and at the top of the stalks; they are of a silvery colour, and appear in June and July. The seeds ripen in autumn, which, if permitted to scatter, the plants will come up without care, and require no other culture, but to keep them clean from weeds.

The eighteenth sort grows naturally at the Cape of Good Hope; this rises with a slender shrubby stalk, which sends out many lateral branches below; these are garnished with very narrow leaves, which are hoary on their under side. The flowers are produced in a compound corymbus at the end of the branches; they are at their first appearance of a pale red colour, but afterward change to a gold colour; the empalements of this sort are small, and dry like the other species of this genus. This sort is propagated by cuttings, in the same manner as the sixteenth, and the plants require the same treatment.

The nineteenth sort grows naturally in Egypt and Palestine. This is a perennial plant, whose under leaves spread near the ground; they are woolly on their under side; the stalks rise about six inches high; the leaves upon these are spear-shaped, ending in acute points; the stalks and leaves are woolly, and the stalk is terminated by a large corymbus of flowers sitting very close; these are of a fine soft red colour, so make a pretty appearance in the month of June, when they are in beauty.

This sort is propagated by offsets in the same manner as the seventh and eighth sorts, but this doth not produce them in plenty, so is very uncommon in the English gardens at present: it requires a drier soil than the seventh, and a warmer situation, but not too much exposed to the mid-day sun, so should be planted to a south-east aspect.

The twentieth sort grows naturally at the Cape of Good Hope, but has been long preserved in many curious gardens in Europe; the stalk rises three or four feet high, sending out several long irregular branches, which are terminated by a compound corymbus

G N I

rymbus of flowers. The heads of this sort are composed of leaves, which are much longer than those of any other sort; the heads of the flowers are of a bright silver colour. This is propagated by cuttings, which should be planted in the same manner as hath been directed for the tenth sort, and the plants should also be treated in the same way.

The twenty-first sort was raised from seeds in the Chelsea garden, which came from the Cape of Good Hope; the lower leaves of this are oblong and blunt. The stalks are shrubby, and divide into many irregular branches, which rise about three feet high; these are garnished with oblong blunt-pointed leaves, hoary on their under side, but of a dark green above; from the base of the leaves runs a border along the stalk, like a wing, of the same consistence with the leaves, so is what the former botanists termed a winged stalk, but Dr. Linnæus calls it a running leaf. The stalks are terminated by a compound corymbus of flowers, which are very closely joined together, and are of a bright gold colour, but the flowers are small, and change to a darker colour as they fade; there is a succession of these flowers most part of the summer, and the early flowers are frequently succeeded by seeds in England. This sort may be propagated by slips, or cuttings, in the same manner as the tenth, and the plants may be treated in the same manner as is directed for that. It is engraven in the 131st plate of the figures of plants.

The twenty-second sort grows naturally in North America, from whence the seeds have been brought to England; this is a perennial plant, whose lower leaves are large and oval; from the main stalk there come out runners, which take root in the ground, and have young plants at their extremity. The stalks are single, and garnished with narrower woolly leaves, placed alternate. The flowers are produced at the top of the stalks in a corymbus, they are of a white colour and small. They appear in June and July, and sometimes are succeeded by seeds, but the plants propagate so fast by offsets, that the seeds are little regarded; this will thrive in the open air, if planted in a dry soil and a warm situation.

The twenty-third sort grows naturally in North America; it is an annual plant, with woolly obtuse leaves. The stalks are single, and rise about nine inches high. The flowers grow in spikes from the side of the stalks; they are of a dirty white colour, so make no great appearance. If the seeds of this are permitted to scatter, the plants will rise without trouble, and only require to be kept clean from weeds.

The twenty-fourth sort grows naturally in Jamaica, and other of the hot parts of America; this rises with a shrubby stalk about two feet high, garnished with leaves about the size and shape of those of Sage, but woolly on their under side, and much veined; from the base of each leaf runs a border along the stalk. The flowers are produced in spikes from the side, and at the end of the stalk; these are long, and closely joined in the spike. It flowers in July and August, but never perfects seeds in England.

It is propagated by seeds, which should be sown on a hot-bed in pots, because the plants do not often rise the same year; therefore when it so happens, the pots should be placed in the stove in winter, and the following spring put upon a fresh hot-bed to bring up the plants; when these appear they must be planted into pots, and kept constantly in the hot-bed, otherwise they will not thrive in England.

GNAPHALODES. See MICROPUS.

GNIDIA.

The CHARACTERS are,

It hath a funnel-shaped empalement of one coloured leaf, with a long tube divided into four segments; the flower hath four plain petals shorter than the empalement inserted to it, and eight bristly erect stamina, terminated by simple summits, and an oval germen supporting a slender style on the side inserted with the stamina, crowned by a stinging stigma; the germen afterward becomes one oval oblique-pointed seed, inclosed in the empalement.

This genus of plants is ranged in the first order of

G O M

Linnæus's eighth class, intitled Octandria Monogynia, the flower having eight stamina and one style.

We have but one SPECIES of this genus, viz.

1. GNIDIA (*Pirifolia*) foliis sparsis lineari-subulatis, floribus verticillatis, aggregatis terminalibus. Lin. Sp. 512. *Gnidia with linear awl-shaped leaves, and flowers placed closely in whorls terminating the branches.* Rapunculus foliis nervosis linearibus, floribus argenteis non galeatis. Burm. Afr. 112.

This plant grows naturally in Æthiopia. It hath a low shrubby stalk, which rises three or four feet high, sending out a few sidebranches, garnished with narrow, oblong, acute-pointed leaves, which are green on their upper side, but pale on their under, with a strong longitudinal nerve, resembling the leaves of Rosemary: the flowers come out almost in whorls from between the leaves on the extremity of the branches, standing on short foot-stalks; they have long slender tubes, and are divided at the top into four segments which spread horizontally, having eight very short stamina in the bottom of the tube, and an oval germen with a slender style fastened to the side of the stamina; the germen is afterward succeeded by one oval-pointed seed. There are two varieties of this, one with a white, and the other hath a blue flower.

This is usually propagated here by cuttings, which if carefully planted during the summer months, in pots filled with light earth, plunged into a very moderate hot-bed, covering the pots closely with either bell or hand-glasses to exclude the air, being careful to shade the glasses daily, the cuttings will put out roots in six weeks, when they should be gradually inured to the open air. In winter the plants should be placed in a dry airy glass-case, where they may enjoy free air in mild weather, but protected from frost and damp air.

GOMPHRENA. Lin. Gen. Plant. 279. Amaranthoides. Tourn. Inst. R. H. 654. tab. 420.

The CHARACTERS are,

The flower hath a large three-leaved empalement, which is coloured and permanent. The petal is erect, and cut into five parts at the top; it hath a cylindrical tubulous empalement the length of the petal, cut into five small parts at the brim, which spread open; it hath five stamina scarcely discernible, situated in the brim of the nectarium, terminated by summits, shut up in the mouth of the nectarium. In the center is situated an oval-pointed germen, with two small styles, crowned with single stigma the length of the stamina. The germen afterward becomes one large roundish seed, inclosed in a thin crusted capsule with one cell.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, which includes the plants whose flowers have five stamina and two styles.

The SPECIES are,

1. GOMPHRENA (*Globosa*) caule erecto, foliis ovato-lanceolatis, capitulis solitariis, pedunculis diphyllis. Hort. Cliff. 86. *Gomphrena with an erect stalk, oval spear-shaped leaves, single heads, and foot-stalks having two leaves.* Amaranthoides Lychnidis folio, capitulis purpureis. Tourn. Inst. R. H. 654. *Globe Amaranthus with purple heads.*
2. GOMPHRENA (*Serrata*) caule erecto, spicâ interruptâ. Prod. Leyd. 419. *Gomphrena with an erect stalk, and an interrupted spike of flowers.*
3. GOMPHRENA (*Perennis*) foliis lanceolatis, capitulis diphyllis, flosculis perianthio proprio distinctis. Lin. Sp. Plant. 224. *Gomphrena with spear-shaped leaves, two leaves to the heads, and each floret having its proper empalement.* Amaranthoides perenne, floribus stramineis radiatis. Hort. Elth. 24. tab. 20. *Perennial Globe Amaranthus with radiated straw-coloured flowers.*

The first sort grows naturally in India, from whence the seeds were brought to Europe, and the plants have been many years cultivated in all the curious gardens: it is an annual plant, which rises with an upright branching stalk about two feet high, garnished with spear-shaped leaves placed opposite. The branches also come out opposite, and the foot-stalks of the flowers, which are long and naked, having two short leaves,

leaves, close under each head of flowers arises from the forks of the branches. The heads at their first appearance are globular, but as they increase in size become oval; these are composed of dry scaly leaves or petals, placed imbricatum like the scales of fish; under each of these is situated a tubulous flower, which just peeps out of the covering, but these are not much regarded by the generality of people; for the scaly empalement which covers them is so beautiful, and these if gathered before they are too much faded, will retain their beauty several years. After the flowers are past, the germen, which is situated in the bottom of each, becomes a large oval seed, inclosed in a chaffy covering, which ripens late in autumn, and the plants decay soon after.

There are two varieties of this sort, one with fine bright purple heads, the other hath white or silvery heads, and these never alter from seeds, so that they are permanent varieties, though in other respects they do not differ: there is also one with mixed colours, but whether this arose accidentally from the seeds of either of the former, I cannot determine, for this variety continues from seeds, and the other two I have cultivated more than thirty years, and have never found either of them vary.

There are also two varieties of these which grow naturally in the West-Indies, one with purple, and the other with white heads, which are much smaller and rounder than those before-mentioned. The plants grow much larger, and spread more into branches, and they are later before they flower, so that in cold seasons the seeds rarely ripen in England; these are called Bachelors Buttons by the inhabitants of America, but whether they are specifically different from the others, I cannot with certainty determine.

The second sort hath much slenderer stalks than the first, which grow taller, and are irregular. The leaves are smaller, but of the same shape. The flowers grow in spikes at the end of the branches, which are broken, or divided into three or four parts with spaces between them. The spikes are small, and of a pale purple colour. The seeds of this sort were sent me by the late Dr. Houstoun from Campeachy.

The third sort hath slender upright stalks, which are garnished with spear-shaped leaves placed opposite; they are hairy, and sit close to the stalks, which also are hairy, and terminated by small heads of flowers, which spread open from each other, so as that the empalement appear distinct; these are of a pale straw colour, and appear in July. The seeds sometimes will ripen in England, but the plants will live two or three years, if they are preserved in a stove.

The two sorts with large heads of flowers which are first mentioned, one with purple, and the other which is silver-coloured, are very ornamental plants in gardens, and are now very commonly cultivated in the English gardens. In Portugal, and other warm countries, they are cultivated to adorn their churches in the winter; for if these are gathered when they are fully grown, and dried in the shade, they will retain their beauty a long time, especially if they are not exposed to the air; these plants are annual, so are only propagated by seeds, which should be sown on a good hot-bed the beginning of March; but if the seeds are not taken out of their chaffy covering, it will be proper to soak them in water for twelve hours before they are sown, which will greatly facilitate their growing. When the plants are come up half an inch high, they should be transplanted on a fresh hot-bed, at about four inches distance, observing to shade them till they have taken root; then they should have fresh air admitted to them every day, in proportion to the warmth of the season; they will also require to be frequently refreshed with water. In about a month's time, if the hot-bed is of a proper warmth, the plants will have grown so large, as to nearly meet, therefore they will require more room, otherwise they will draw up weak; then a fresh hot-bed should be prepared, into which there should be a sufficient number of three farthing pots plunged, filled with light

rich earth, and when the bed is in a proper temperature of warmth, the plants should be carefully taken up with balls of earth to their roots, and each planted into a separate pot, observing to shade them till they have taken new root, afterward they must be treated in the same manner as other tender exotic plants. When the plants have filled these pots with their roots, they should be shaken out of the pots, and their roots on the outside of the ball of earth must be carefully pared off; then they should be put into pots a size larger, and when there is conveniency of a deep frame, to plunge the pots into another gentle hot-bed, it will bring the plants early to flower, and cause them to grow much larger than those which are placed abroad. In July the plants should be inured gradually to bear the open air, into which they may be removed about the middle of that month, and intermixed with other annual plants to adorn the pleasure-garden; but it will be proper to keep a plant or two of each sort in shelter for seeds, because when the autumn proves cold or wet, those plants which are exposed abroad, seldom produce good seeds.

GOOSEBERRY. See GROSSULARIA.

GORTERIA.

The CHARACTERS are,

The empalement of the flower is stiff, scaly, ending in bristly spines; the flower is composed of hermaphrodite florets in the disk, and female in the rays or border; the hermaphrodite florets are funnel-shaped, five-pointed, having five short stamina terminated by cylindrical summits, with a hairy germen supporting a slender style, crowned by a bifid stigma; the germen afterward becomes one roundish seed, surrounded by fine hairs. The female florets are tongue-shaped, have no style or stigma, and are barren.

This genus of plants is ranged in the third section of Linnæus's nineteenth class, intitled Syngenesia Polygamia frustranea, the flowers being composed of hermaphrodite florets in the disk which are fruitful, and female florets in the border, having neither style or stigma, so are barren.

The SPECIES are,

1. GORTERIA (*Ringens*) scapis unifloris, foliis lanceolatis pinnatifidis, caule depresso. Amoen. Acad. 6. p. 86. *Gorteria with one flower on each foot-stalk, spear-shaped, wing-pointed leaves, and a depressed stalk.* Arctotis ramis decumbentibus, foliis lineari-lanceolatis rigidis subtus argenteis. Ed. prior.
2. GORTERIA (*Fruticosa*) foliis lanceolatis integris dentato-spinosis subtus tomentosis, caule fruticoso. Lin. Sp. 1284. *Gorteria with entire spear-shaped leaves, whose indentures end in spines, woolly on their under side, and a shrubby stalk.* Carthamus Africanus frutescens, folio ilicis, flore aurco. Walth. Hort. 13. tab. 7.

The first sort grows naturally at the Cape of Good Hope; it is a low spreading plant, with ligneous stalks six or eight inches long trailing on the ground, having two or three side branches, each terminating in a close head of leaves, which are narrow, green on their upper side, but silvery on their under, cut into three or five segments at their ends. The foot-stalks of the flowers arise from the heads, and are six inches long, naked, supporting one large Orange-coloured flower at the top, composed of several hermaphrodite florets in the disk, which are fruitful; but the female half florets on the border are tongue-shaped, spreading open, each having a dark mark toward their base, with a white spot intermixed. The flowers appear in May and June, but are seldom succeeded by seeds in England.

This plant is easily propagated by cuttings planted in a shady border during any of the summer months, and the plants must be afterward treated as is directed for ARCTOTIS.

The second sort grows naturally at the Cape of Good Hope. This rises with a shrubby slender stalk three feet high, sending out a few weak branches, garnished with oblong leaves sitting close to the branches; they are smooth on their upper side, woolly underneath, and indented on their edges, each indenture ending with a weak spine. The flowers terminate the stalks, having

having leafy empalements ending with spines; the flowers are yellow, and appear in the summer months, but are not succeeded by seeds in England.

It is propagated by planting of the small heads at the end of the branches, in June or July, which must be closely covered with either bell or hand-glasses, or they will not succeed, and should be carefully screened from the sun. When these are well rooted, they should be put each into a small pot, and in winter should be placed in an airy glass-case secure from damps.

G O R Z. See U L E X.

G O S S Y P I U M. Lin. Gen. Plant. 755. Xylon. Tourn. Inst. R. H. 101. tab. 27. Cotton:

The CHARACTERS are,

The flower has a double empalement; the outer is large, of one leaf, and cut half way into three segments; the inner is cup-shaped, of one leaf, cut into five obtuse segments at the top. It hath five plain heart-shaped petals, which join at their base, and spread open. It hath a great number of stamina, which are joined at bottom in a column, but are loose above, and inserted into the petals; these are terminated by kidney-shaped summits. It hath a round germen, supporting four styles, joined in the column, and are the same length of the stamina, crowned by four thick stigmas. The germen afterward becomes a roundish capsule, ending in a point, having four cells, which are filled with oval seeds, wrapped up in down.

This genus of plants is ranged in the third section of Linnæus's sixteenth class, intitled Monodelphia Polyandria, which includes the plants whose flowers have many stamina, which are joined together with the styles in one column or body.

The SPECIES are,

1. G O S S Y P I U M (*Herbaceum*) foliis quinquelobis, caule herbaceo lævi. Hort. Upsal. 203. Cotton with leaves having five lobes, and a smooth herbaceous stalk. Gossypium. Camer. Epit. 203. The common herbaceous Cotton.
2. G O S S Y P I U M (*Barbadense*) foliis trilobis integerrimis subtus biglandulosis. Hort. Upsal. 205. Cotton-tree with entire leaves, having three lobes with three glands under their side. Gossypium frutescens annum, folio trilobo Barbadosense. Pluk. Alm. 172. tab. 188. Shrubby annual Barbadoes Cotton, with leaves having three lobes.
3. G O S S Y P I U M (*Arboreum*) foliis palmatis, lobis lanceolatis, caule fruticoso. Lin. Sp. Plant. 693. Cotton with hand-shaped leaves, having five spear-shaped lobes, and a shrubby stalk. Xylon arboreum, flore flavo. Tourn. Inst. R. H. 101. Tree Cotton with a yellow flower.
4. G O S S Y P I U M (*Hirsutum*) foliis trilobis & quinquelobisque acutis, caule ramoso hirsuto. Cotton with leaves having three and five lobes, ending in acute points, and a hairy branching stalk. Xylon Americanum præstantissimum, semine virescente. Lign. Tourn. Inst. R. H. 101. Finest American Cotton with a green seed.

The first sort is the common Levant Cotton, which is cultivated in several Islands of the Archipelago, as also in Malta, Sicily, and the kingdom of Naples; it is sown in tilled ground in the spring of the year, and is ripe in about four months after, when it is cut down in harvest as Corn is in England; the plants always perish soon after the seeds are ripe: this plant grows about two feet high, with an herbaceous stalk, garnished with smooth leaves divided into five lobes. The stalks send out a few weak branches upward, which are garnished with leaves of the same form but smaller. The flowers are produced near the extremity of the branches, at the foot-stalks of the leaves; these have two large empalements, the outer is cut into three parts, and the inner into five. The petals of the flower are of a pale yellow colour, inclining to white; these are succeeded by oval capsules, which open in four parts, having four cells, which are filled with seeds wrapped up in down, which is the Cotton.

The second sort grows naturally in several islands of the West-Indies; this rises with a shrubby smooth stalk four or five feet high, sending out a few side branches, which are garnished with smooth leaves, divided into three lobes. The flowers are produced toward the end of the branches, which are shaped like those of

the former sort, but are larger, and of a deeper yellow colour. The pods are larger, and the seeds are black.

The third sort hath a perennial shrubby stalk, which rises six or eight feet high, and divides into many smooth branches; garnished with hand-shaped leaves; having four or five lobes. The flowers are produced toward the end of the branches; these are larger than those of the two former sorts, and are of a deep yellow colour. The pods of this sort are larger than those of the former.

The fourth sort is a native of the East and West-Indies, from whence the seeds have been brought to Europe; this is also an annual plant, which perishes soon after the seeds are ripe. It rises to the height of three feet or more, and sends out many lateral branches, which extend to a great distance, where they are allowed room to grow; these are hairy, and garnished with leaves; having in some three, and others five acute-pointed lobes, with short hairy down on their surface. The flowers are produced from the side, and at the end of the branches; these are large, of a dirty sulphur colour, each petal having a large purple spot at the base, and are succeeded by oval pods, which open into four cells, which are filled with oblong green seeds wrapped up in a soft down. Where the plants have room to spread, their branches will produce four or five pods of Cotton upon each, so that from a single plant, thirty or more pods may be produced; and each of these are as large as middling Apples, so there will be a much greater produce from this than from any other sort, and the staple is much finer; therefore it is well worth the attention of the inhabitants of the British colonies in America to cultivate and improve this sort, since it will succeed in Carolina, where it has been cultivated for some years; and might be a commodity worthy of encouragement by the public, could they contrive a proper gin to separate the Cotton from the seeds, to which this sort adheres much closer than any of the other sorts, the Cotton from this shrub being preferable to any other yet known. All these sorts are very tender plants, therefore will not thrive in the open air in England; but they are frequently sown in curious gardens for variety: the first and fourth sorts will produce ripe seeds in England, if their seeds are sown early in the spring, upon a good hot-bed; and when the plants are come up, planted each into separate pots; and plunged into a hot-bed of tanners bark to bring them forward; and when they are grown too tall to remain under the frames, removed into the tan-bed in the stove, and shifted into larger pots, when their roots have filled the other; with this management I have had their flowers appear in July, and toward the end of September the seeds have been perfectly ripe, and the pods as large as those produced in the East and West-Indies; but if the plants are not brought forward early in the spring, it will be late in the summer before the flowers will appear, and there will be no hopes of the pods coming to perfection.

The Shrub-cotton will rise from the seeds very easily, if they are sown upon a good hot-bed; and when they are sown early in the spring, and brought forward in the same manner as hath been directed for the former sorts, the plants will grow to be five or six feet high the same summer; but it is difficult to preserve the plants through the winter, unless they are hardened gradually in August during the continuance of the warm weather; for when they are forced on at that time, they will be so tender, as to render them incapable of resisting the least injury. The plants of this sort must be placed in the bark-stove in autumn, and kept in the first class of heat, otherwise they will not live through the winter in England.

G R A F T I N G is the taking a shoot from one tree, and inserting it into another, in such a manner, as that both may unite closely, and become one tree; this is called by the ancient writers in husbandry and gardening, incision, to distinguish it from inoculating, or budding, which they call *inserere oculos*.

The use of grafting is to propagate any curious sorts of fruits, so as to be certain of the kinds, which cannot be done by any other method; for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as are not worth cultivating; but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock, or tree, on which they are grafted; for though the grafts receive their nourishment from the stocks, yet their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken; the only alteration is, that when the stocks on which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they will not make near so great progress as they otherwise would do, nor will the fruit they produce be so fair, and sometimes not so well flavoured.

These shoots are termed cions, or grafts; in the choice of these the following directions should be carefully observed. 1st, That they are shoots of the former year, for when they are older, they never succeed well. 2dly, Always to take them from healthy fruitful trees, for if the trees are sickly from whence they are taken, the grafts very often partake so much of the distemper as rarely to get the better of it, at least for some years; and when they are taken from young luxuriant trees, whose vessels are generally large, they will continue to produce luxuriant shoots, and are seldom so fruitful as those which are taken from fruitful trees, whose shoots are more compact, and the joints closer together; at least it will be a great number of years before the luxuriant grafts begin to produce fruit, if they are managed with the greatest skill. 3dly, You should prefer those grafts which are taken from the lateral, or horizontal branches, to those from the strong perpendicular shoots, for the reasons before given.

These grafts, or cions, should be cut off from the trees before their buds begin to swell, which is generally three weeks or a month before the season for grafting; therefore, when they are cut off, they should be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood is cut off with the cion, it will preserve it the better, and when they are grafted, this may be cut off; for at the same time the cions must be cut to a proper length before they are inserted in the stocks; but, till then, the shoots should remain their full length, as they were taken from the tree, which will preserve them better from shrinking; if these cions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month, or longer; but these should be cut off earlier from the trees than those which are to be grafted near the place where the trees are growing.

Having given directions for the cions and grafts, we next come to that of the stock, which is a term applied to the trees intended for grafting; these are either such old trees as are already growing in the places where they are to remain, whose fruit is intended to be changed, or young trees, which have been raised in a nursery for a supply to the garden; in the former case there is no other choice, but that of the branches, which should be such as are young, healthy, well situated, and have a smooth bark; if these trees are growing against walls, or espaliers, it will be proper to graft six, eight, or ten branches, according to the size of the trees, by which they will be much sooner furnished with branches again, than when a less number of cions are put in; but in standard-trees, four, or at most six cions will be sufficient.

In the choice of young stocks for grafting, you should always prefer such as have been raised from the

seed, and that have been once or twice transplanted. Next to these, are those stocks which have been raised from cuttings, or layers, but those which are suckers from the roots of other trees should always be rejected, for these are never so well rooted as the others, and constantly put out a great number of suckers from their roots, whereby the borders and walks of the garden will be always pestered with them during the summer season, which is not only unsightly, but they also take off part of the nourishment from the trees.

If these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened, and more compact than those which have grown close and have been there drawn up to a greater height; the wood of these will be soft, and their vessels large, so that the cions grafted into them will shoot very strong, but they will be less disposed to produce fruit than the other; and when trees acquire an ill habit at first, it will be very difficult to reclaim them afterward.

Having directed the choice of cions and stocks, we come next to the operation, in order to which you must be provided with the following tools.

1. A neat small hand-saw to cut off the heads of large stocks.
2. A good strong knife with a thick back, to make clefts in the stocks.
3. A sharp penknife to cut the grafts.
4. A grafting chisel and a small mallet.
5. Bals strings, or woollen yarn, to tie the grafts with, and such other instruments and materials as you should find necessary, according to the manner of grafting you are to perform.
6. A quantity of clay, which should be prepared a month before it is used, and kept turned and mixed, like mortar every other day, which is to be made after the following manner:

Get a quantity of strong fat loam (in proportion to the quantity of trees intended to be grafted, then take some new stone-horse dung, and break it in amongst the loam, and if you cut a little straw, or hay, very small, and mix amongst it, the loam will hold together the better; and if there be a quantity of salt added, it will prevent the clay from dividing in dry weather; these must be well stirred together, putting water to them after the manner of making mortar; it should be hollowed like a dish, and filled with water, and kept every other day stirred; but it ought to be remembered, that it should not be exposed to the frost, or drying winds, and the oftener it is stirred and wrought the better.

Of late years some persons have made use of another composition for grafting, which they have found to answer the intention of keeping out the air, better than the clay before described. This is composed of turpentine, bees-wax, and rosin, melted together, which, when of a proper consistence, may be put on the stock round the graft, in the same manner as the clay is usually applied; and though it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay; and as cold will harden this, there is no danger of its being hurt by frost, which is very apt to cause the clay to cleave, and sometimes fall off; and when the heat of summer comes on, this mixture will melt, and fall off without any trouble. In using of this, there should be a tin, or copper-pot, with conveniency under it to keep a very gentle fire with small-coal, otherwise the cold will soon condense the mixture; but you must be careful not to apply it too hot, lest you injure the graft. A person who is a little accustomed to this composition, will apply it very fast, and it is much easier for him than clay, especially if the season should prove cold. There are several ways of grafting, the principal of which are four:

1. Grafting in the rind, called also shoulder-grafting, which is only proper for large trees; this is called crown-grafting, because the grafts are set in form of a circle, or crown, and is generally performed

formed about the latter end of March, or the beginning of April.

2. Cleft-grafting, which is also called stock, or slit-grafting; this is proper for trees or stocks of a lesser size, from an inch, to two inches or more diameter; this grafting is to be performed in the months of February and March, and supplies the failure of the escutcheon way, which is practised in June, July, and August.

3. Whip-grafting, which is also called tongue-grafting; this is proper for small stocks of an inch, half an inch, or less, diameter; this is the most effectual way of any, and which is most in use.

4. Grafting by approach, or ablactation; this is to be performed when the stock you would graft on, and the tree from which you take your graft, stand so near together, that they may be joined; this is to be performed in the month of April, and is also called inarching, and is chiefly used for Jasmynes, Oranges, and other tender exotic trees.

We come next to the manner of performing the several ways of grafting.

The first method, which is termed rind, or shoulder-grafting, is seldom practised but on large trees, where either the head, or the large branches, are cut off horizontally, and two or four cions put in, according to the size of the branch, or stem; in doing of this, the cions are cut flat on one side, with a shoulder to rest upon the crown of the stock; then the rind of the stock must be raised up, to admit the cion between the wood and the bark of the stock, which must be inserted about two inches, so as the shoulder of the cion may meet, and closely join the crown of the stock; and after the number of cions are inserted, the whole crown of the stock should be well clayed over, leaving two eyes of the cions uncovered therewith, which will be sufficient for shooting; this method of grafting, was much more in practice formerly than at present; the discontinuance of it was occasioned by the ill success it was attended with; for as these cions were placed between the rind of the stock and the wood, so they are frequently blown out by strong winds, after they had made large shoots, which has sometimes happened after five or six years growth; so that whenever this method is practised, there should be some stakes fastened to support the cions, until they have almost covered the stock.

The next method is termed cleft, or stock-grafting; this is practised upon stocks, or trees, of a smaller size, and may be used with success, where the rind of the stock is not too thick, whereby the inner bark of the cion will be prevented joining to that of the stock; this may be performed on stocks, or branches, which are more than one inch diameter; in the doing of this, the head of the stock, or branch, must be cut off with a slope, and a slit made the contrary way, in the top of the slope, deep enough to receive the cion, which should be cut sloping like a wedge, so as to fit the slit made in the stock, being careful to leave that side of the wedge, which is to be placed outward, much thicker than the other; and in putting the cion into the slit of the stock, there must be great care taken to join the rind of the cion to that of the stock; for if these do not unite, the grafts will not succeed: when this method of grafting is used to stocks which are not strong, it will be proper to make a ligature of bafs, to prevent the slit of the stock from opening; then the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the cions above the clay for shooting.

The third method is termed whip, or tongue-grafting, which is the most commonly practised of any by the nurserymen near London, especially for small stocks, because the cions much sooner cover the stocks in this method than in any other.

This is performed by cutting off the head of the stocks sloping; then there must be a notch made in the slope toward the upper part downward, a little more than half an inch deep, to receive the cion, which must be cut with a slope upward, and a slit made in this slope like a tongue, which tongue must be in-

serted into the slit made in the slope of the stock, and the cion must be placed on one side of the stock; so as that the two rinds of both cion and stock may be equal, and join together exactly; then there should be a ligature of bafs to fasten the cion, so as that it may not be easily displaced; and afterward clay it over, as in the former methods.

The fourth sort of grafting is termed inarching-grafting by approach, or ablactation. This is only to be performed when the stocks, which are designed to be grafted, and the tree from which the graft is to be taken, stand so near together, or may be brought so near together, as that their branches may be united; this method of grafting is commonly practised on tender exotic plants, and some other sorts which do not succeed in any of the other methods.

In performing this operation, a part of the stock, or branch, must be slit off about two inches in length, observing always to make choice of a smooth part of the stock; then a small notch should be made in this slit of the stock downward, in the same manner as hath been directed for whip-grafting; then the branch of the tree designed to be inarched, should have a part slit off in like manner as the stock, and a slit made upward in this, so as to leave a tongue; which tongue should be inserted into the slit of the stock, observing to join their rinds equally, that they may unite well together; then make a ligature of bafs, to keep them exactly in their situation, and afterward clay this part of the stock over well, to keep out the air; in this method of grafting, the cion is not separated from the tree, until it is firmly united with the stock, nor is the head of the stock, or branch, which is grafted, cut off till this time, and only half the wood pared off with a slope, about three inches in length, and the same of the cion, or graft.

This method of grafting is not performed so early in the season as those of the other, it being done in the month of April, when the sap is flowing, at which time the cion and stock will join together, and unite much sooner than at any other season.

The Walnut, Fig, and Mulberry, will take by this method of grafting, but neither of these will succeed in any of the other methods; there are also several sorts of Evergreens, which may be propagated by this method of grafting; but all the trees which are grafted in this way are weaker, and never grow to the size of those which are grafted in the other methods; therefore this is rarely practised, but on such sorts of trees as will not take by the other methods.

The next thing which is necessary to be known, by those who would practise this art, is, what trees will take and thrive by being grafted upon each other; and here there have been no sure directions given by any of the writers on this subject, for there will be found great mistakes in all their books, in relation to this matter; but as it would swell this article too great, if all the sorts of trees were to be here enumerated, which will take upon each other by grafting, I shall only mention such general directions, as, if attended to, will be sufficient to instruct persons, so as they may succeed.

All such trees as are of the same genus, i. e. which will agree in their flower and fruit, will take upon each other: for instance, all the Nut-bearing trees may be safely grafted on each other, as may all the Plumb-bearing trees, under which head I reckon not only the several sorts of Plumbs, but also the Almond, Peach, Nectarine, Apricot, &c. which agree exactly in their general characters, by which they are distinguished from all other trees; but as many of these are very subject to emit large quantities of gum from the parts of the trees as are deeply cut and wounded, so the tender trees of this kind, viz. Peaches and Nectarines, which are most subject to this, it is found to be the surest method to bud or inoculate these sorts of fruits, for which see INOCULATION.

Then all such trees as bear cones will do well upon each other, though they may differ in one being evergreen, and the other shedding its leaves in winter; as is observable in the Cedar of Libanus, and the Larch-tree, which are found to succeed upon each other very well;

well; but these must be grafted by approach, for they abound with a great quantity of resin which is apt to evaporate from the graft, if separated from the tree before it is joined with the stock, whereby they are often destroyed; as also the Laurel on the Cherry, or the Cherry on the Laurel. All the mast-bearing trees will also take upon each other, and those which have a tender soft wood will do well if grafted in the common way; but those that are of a more firm texture, and are slow growers, should be grafted by approach.

By strictly observing this rule, we shall seldom miscarry, provided the operation be rightly performed, and at a proper season, unless the weather should prove very bad, as it sometimes happens, whereby whole quarters of fruit-trees miscarry; and it is by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; for, being grafted upon stocks of the same sort which are hardy, the grafts are rendered more capable to endure the cold, as hath been experienced by most of our valuable fruits now in England, which were formerly transplanted here from more southerly climates, and were at first too impatient of our cold to succeed well abroad; but have been, by budding or grafting upon more hardy trees, rendered capable of resisting our severest cold.

And these different graftings seem to have been greatly in use among the ancients, though they were certainly mistaken in the several sorts of fruits which they mention to have succeeded upon each other; as the Fig upon the Mulberry, the Plumb upon the Chestnut, with many others of the like kind; most of which I have already tried, and find they will not succeed; therefore what has been advanced on this head by the ancients, is not founded on experience; or at least they did not mean the same plants, which at present are called by those names; though I cannot help thinking we are apt to pay too much deference to the writings of the ancients, in supposing them seldom to be mistaken, or to assert a falsehood; whereas, if their works are carefully examined, it will be found, that they have often copied from each other's writings, without making experiments to prove the truth of their assertions: and it is well known, that the ranging of plants before Cæsalpinus's time (which is about 170 years since) was, by their outward appearance, or from the supposed virtues of them, which method is now justly exploded; and it hath been observed, from many repeated trials, that however plants may resemble each other in the shape and make of their leaves, manner of shooting, &c. unless they agree in their fruit, and their other distinctive characters, they will not grow upon each other, though performed with ever so much art.

GRAMEN. Tourn. Inst. R. II. 516. tab. 297. Raii Meth. Plant. 171. Grass; in French, *Chien-dent*.

To enumerate all the species of Grass which are found growing naturally in England, would swell this article greatly beyond the design of the work; therefore I shall only take notice of a few species, which are either used in medicine, or cultivated for fodder; for there is scarce a pasture in this country, where at least twenty different species are not to be found intermixed, and in most of them more than twice that number. These were, by the former writers on botany, all included under the common denomination of Gramen, but were divided into different sections. Mr. Ray has ranged them in the following order, Gramen Triticum, i. e. Wheat-grass. Gramen Secalinum, i. e. Rye-grass. Gramen Loliaceum, i. e. Darnel-grass. Gramen Paniceum, i. e. Panic-grass. Gramen Phalaroides, i. e. Canary-grass. Gramen Alopecuroides, i. e. Fox-tail-grass. Gramen Typhinum, i. e. Cat's-tail-grass. Gramen Echinatum, i. e. Hedgehog-grass. Gramen Cristatum, i. e. Crested-grass. Gramen Avenacium, i. e. Oat-grass. Gramen Dactylon, i. e. Cock's-foot-grass. Gramen Arundinaceum, i. e. Reed-grass. Gramen Milleacem, i. e.

Millet-grass. And under each of these sections there are many species. And there are many others, which, by older writers, were included under this general title, some of which have no relation to this class; but there are others which are near nearly allied to it, as the Cyperus, and Cypress Grasses, &c. These Dr. Linnæus has divided into genera; but by this method of classing them, he has separated them to a great distance from each other; for all those whose flowers have three stamina, are ranged in his third class; and others which have male and female flowers, are removed to his twenty-first class. However, it would have been much better to have kept them together, as Dr. Van Royen has done in the Prodomus of the Leyden garden, under one general title to the class of Graminea.

As the several genera under which the different species of Grass are ranged, have different characters by which they are distinguished, so it would be to little purpose to give them all in this work; and as there are no general characteristics by which the whole class can be known, so I shall not trouble the reader with any of them here, but proceed to enumerate a few of the species.

1. GRAMEN spica triticea repens vulgare, caninum dictum. Raii Syn. 2. p. 247. Common creeping Grass with a spike like Wheat, called Dog-grass. Triticum calycibus subulatis trifloris acuminatis. Lin. Sp. Plant. Wheat with an awl-shaped pointed empalement including three flowers, commonly called Couch, Couch-grass, or Quick-grass.
2. GRAMEN loliaceum, angustiore folio & spica. C. B. P. Darnel-grass, with a narrower leaf and spike. Lolium spica mutica. Lin. Sp. Plant. 83. Darnel with a chaffy spike, commonly called Ray, or Rye-grass.
3. GRAMEN pratense, paniculatum majus angustiore folio. C. B. P. 2. Meadow-grass with larger panicles and a narrower leaf. Poa panicula diffusa, spiculis quadrifloris pubescentibus, culmo erecto tereti. Flor. Suec. 77. Poa with a diffused panicle, the smaller spikes having four hairy flowers, and a taper erect straw.
4. GRAMEN pratense, paniculatum majus, latiore folio. C. B. P. 2. Meadow-grass with a larger panicle and broader leaf. Poa panicula diffusa spiculis trifloris glabris, culmo erecto tereti. Flor. Suec. 76. Poa with a diffused panicle, small spikes with three flowers, and an upright straw.
5. GRAMEN avenacium pratense elatius panicula flavescens, locustis parvis. Raii Syn. 407. Taller Meadow Oat-grass, with a yellowish panicle and small husks. Avena panicula laxa, calycibus trifloris brevibus, flosculis omnibus aristatis. Prod. Leyd. 66. Oat-grass with a loose panicle, three flowers in each empalement, which is short, and all the flowers having awns.
6. GRAMEN secalinum. Ger. Emac. lib. 1. cap. 22. n. 4. Tall Meadow Rye grass.
7. GRAMEN tremulum maximum. C. B. P. 2. Greatst Quaking-grass, or Cowquakes. Briza spiculis cordatis, flosculis septendecim. Hort. Cliff. 23. Briza with heart-shaped little spikes, and seventeen flowers in each.

The first sort of Grass is that which is directed to be used in medicine; the roots of this are chiefly used, and are accounted aperitive and diuretic, opening obstructions of the reins and bladder, provoking urine, and are of service against the gravel and stone. The juice of the leaves and stalks was greatly esteemed by Dr. Boerhaave, who generally prescribed this in all cases where he supposed there were any obstructions in the bile conduit.

This hath a creeping root, which spreads far in the ground, and is a very troublesome weed in gardens and arable land; for every small piece of the root will grow and multiply exceedingly, so it is very difficult to extirpate where it once gets possession: in gardens, the common method of destroying it is, to fork out the roots as often as the blades appear above ground; where this is two or three times carefully repeated, it may be totally rooted out; but when the surface of the ground is very full of the roots of this Grass, the shortest way of destroying it, is to trench the

the ground two spits and a shovelling deep, turning all the couch into the bottom, where it will rot, and never shoot up; but this can only be practised, where there is a sufficient depth of soil; for in shallow ground the roots cannot be buried so deep, as to lie below the depth to which they naturally shoot.

Where the roots of this Grass get possession in arable fields, it is very difficult to root out again; the usual method is by laying the land fallow in summer, and frequently harrowing it well over to draw out the roots: where this is carefully practised, the ground may be so well cleaned in one summer, as that the roots cannot much injure the crop which may be sown upon it; but such land should be cropped with Beans, Peas, or such things as require the horse-hoeing culture; for where the land can be frequently stirred and harrowed afterward, it will be of great service in cleaning it from the roots of this Grass and other bad weeds. The blade of this Grass is so rough, that cattle will not feed upon it.

The second sort is frequently cultivated, especially in strong cold land, upon which this Grass will succeed better than any other species, and is an earlier feed in the spring; but this is a very coarse Grass, and unless it is cut very early for hay, it becomes hard and wiry in the stalks, so that few cattle care to eat it; for this species has but few leaves, running all to stalk, so is usually called Bents, and in some counties Bennet; when this grass is fed, it will be proper to mow off the Bents in the beginning of June, otherwise they will dry upon the ground, and have the appearance of a stubble field all the latter part of summer; so that it will not only be very disagreeable to the sight, but also be troublesome to the cattle that feed on it, by tickling their nostrils; so that the want of better pasture only, will force them to eat of the young Grass which springs up between these Bents, for those they will not touch; therefore those who suppose that these are eaten in scarcity of feed by the cattle, are greatly mistaken; for I have many years closely attended to this, and have always found these Bents remaining on the ground untouched, till the frost, rain, and winds, destroy it in winter; and, by permitting these to stand, the after-growth of the Grass is greatly retarded, and the beautiful verdure is lost for three or four months; so that it is good husbandry to mow them before they grow too dry, and rake them off the ground: if these are then made into the hay, it will serve for cart-horses or cows feed in winter, and will pay the expence of mowing it.

There is another species of this Grass called Red Darnel, which is of a worse nature than the first, the stalks growing hard much sooner, and having narrower leaves. This is very common in most pasture grounds, for as it comes early to flower, so the seeds are generally ripe before the hay is cut, and from the falling seeds the ground is supplied with plenty of this sort; therefore those who are desirous to keep their pastures as clear from this Grass as possible, should always mow it before the seeds are ripe.

This Grass is usually sown with Clover, upon such lands as are designed to be ploughed again in a few years, and the common method is to sow it with Spring Corn; but from many repeated trials, I have always found, that by sowing these seeds in August, when there has happened a few showers to bring up the Grass, that the crop has answered much better than any which has been sown in the common way; for the Grass has often been so rank, as to afford a good feed the same autumn; and the following spring there has been a ton and a half of hay per acre mowed very early in the season, and this has been upon cold four land; so that I am convinced of that being the best season for sowing these Grasses, though it will be very difficult to persuade those persons to alter their practice, who have been long wedded to old customs. The quantity of seeds which I allow to an acre is about two bushels, and eight pounds of the common Clover, which, together, will make as good plants upon the

ground as can be desired; but this is not to be practised upon such lands where the beauty of the verdure is principally regarded, therefore is fit for those who have only profit in view.

The third and fourth sorts are the two best species of Grass for pastures, so that if the seeds of these were carefully collected and sown separately without any other mixture of Grass-seeds, they would not only afford a greater quantity of seed on the same space of land, but the Grass would also be better, the hay sweeter, and the verdure more lasting than of any other sorts; but there requires some attention to the saving of these seeds pure without mixture. I have tried to save the seeds of several species of Grass separately, in order to determine their qualities, but have found it very difficult to keep them distinct in gardens where the seeds of other sorts of Grass have been scattered: the only method in which I could succeed, was by sowing each species in a distinct pot, and when the plants came up, to weed out all the other kinds of Grass which came up in the pots; by this means I preserved a great variety of the grassy tribe several years, but not having ground enough to propagate the most useful species in any quantity, I was obliged to abandon the pursuit: but I must recommend this to persons of leisure and skill who have a sufficient quantity of land for the purpose, to carry this project into execution, which may be of singular benefit to the public; for we have an instance of the advantage which the inhabitants of the Netherlands have made, by saving the seeds of the White Clover, or Honeyfuckle Trefoil, which is a plant common to most of the English pastures; yet few persons in this country ever gave themselves the trouble to collect the seeds from the fields for sowing, but have purchased vast quantities of this seed annually, at a considerable price from Flanders, where the peasants have been so industrious, as to collect the seeds and sow great quantities of land with it, with a view of sale to this country only. This is not an inconsiderable article in husbandry, but deserves the attention of all those, who, by choice or otherwise, are engaged in the business of agriculture; for one acre of land will produce as much seeds of this species of Trefoil, as will sell for 12 l. where it is well planted and saved from the spring crop; and if the Grass-seeds before-mentioned were separately sown, and carefully weeded from all other species, and permitted to stand till their seeds were ripe, it might be of equal advantage with the other, especially now, when every gentleman is endeavouring to improve the verdure near their habitations.

The fifth and sixth sorts are also very good Grasses for pastures, and have perennial roots, so are the next best sorts for sowing to those before-mentioned, which, in my opinion, deserve the preference to all the other; but as it will be difficult to save a sufficient quantity of seeds of those alone, to supply the demand which may be for their seeds; so these two species may be admitted in aid of the other, as they are very leafy kinds of Grass, and their stalks do not become stiff and harsh like many other species, but with proper care may be made very fine; and, if duly rolled, their roots will mat and form a very close sward, therefore these should be included in the number of sown Grasses.

The seventh sort is mentioned for the sake of variety, and not for use; this hath an annual root, which sends up many broad hairy leaves, between which arise slender stiff stalks from a foot to near two two feet high, dividing upward into a large loose panicle, garnished with heart-shaped small spikes, each having about seventeen small floscules or florets; these, after the flowers are past, have a single seed succeeding them; the heads hang by slender long foot-stalks, which are moved by every wind, so that they generally appear shaking, from whence it had the title of Quaking Grass. There are four species of this Grass; two of them grow naturally in England; and these Grasses coming to head in May, occasioned the following

English proverb, *May come she early come she late, makes the cow quake.* The large sort here mentioned, grows naturally in the south of France and Italy, and is only preserved in some English gardens for the sake of variety.

If the seeds of this sort are sown in the autumn, or permitted to scatter when ripe, the plants will come up stronger, and flower much earlier, than when they are sown in the spring, so good seeds may always be expected from them, which can seldom be attained from the spring plants in England; and as two or three plants of this sort will be full enough in a garden for variety, so these should be allowed to spread; for where they grow at a distance from each other, the roots will send out a great number of stalks, which will be stronger, and produce much larger panicles than those which are too near together.

The Cock's-foot Grass, Capon's-tail Grass, and Millet Grasses are too coarse to deserve attention in England, though some of their species are very useful in the warm parts of America, where there is a great scarcity of finer Grass; and some of these are much better adapted to those warm countries, than any of our European Grasses, for many of them lie flat on the ground, and emit roots from their joints, so are well prepared for heat; their stalks are large and juicy, so will live in heat where few of the European Grasses can be made to thrive.

The land on which Grass-seed is intended to be sown, should be well ploughed, and cleared from the roots of noxious weeds, such as Couch-grass, Fern, Rushes, Heath, Gorse, Broom, Rest-harrow, &c. which, if left in the ground, will soon get the better of the Grass, and over-run the land. Therefore in such places where either of these weeds abound, it will be a good method to plough up the surface in April, and let it lie some time to dry; then harrow the roots into small heaps, and burn them. The ashes so produced, when spread on the land, will be a good manure for it. The method of burning the roots is particularly directed under the article LAND, which see: but where Couch-grass, Fern, or Rest-harrow is in plenty, whose roots run far under ground, the land must be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off after each ploughing, which is the most sure method to destroy them. Where the land is very low, and of a stiff clayey nature, which holds water in winter, it will be of singular service to make some under-ground drains to carry off the wet; which, if detained too long on the ground, will render the Grass sour. The method of making these drains is prescribed under the article LAND, which see.

Before the seed is sown, the surface of the ground should be made level and fine, otherwise the seed will be buried unequal. When the seed is sown, it must be gently harrowed in, and the ground rolled with a wooden roller, which will make the surface even, and prevent the seeds being blown in patches. When the Grass comes up, if there should be any bare spots, where the seed has not grown, they may be sown again, and the ground rolled, which will fix the seeds; and the first kindly showers will bring up the Grass, and make it very thick.

Where the land is designed to continue in pasture, it should be sown with the best sorts of Grass-seeds, and white Dutch Clover, or what is commonly called Honey-suckle Grass in many parts of England, but there is a great difficulty of procuring hay-seeds which are good; for in all the good pastures near London, which abound with the best sorts of Grass, the hay is commonly cut before the seeds of the Grass are ripe; so that those seeds which are procured from the stables where the horses are fed with the best sort of hay, are little more than chaff, or at best are only such as are of the early kinds of Grass, with a great quantity of Plantain and other weeds: which has discouraged many gentlemen from sowing them, nor has any one attempted to save these seeds properly; and as it requires longer time, and more attention, to save a quantity of

seeds of the purer sort of Grass than the generality of people care to bestow, so I would recommend the setting some of those upland pastures, which are cleanest from weeds, and have the sweetest herbage aside, to stand for seeds; and although by so doing the hay will be less valuable, yet from the sale of the seeds, it may answer better to the possessor, than to mow it merely for the hay; for any gentleman who has regard to the beauty of his land, had better give six times the price for such seeds, as is usually paid for the ordinary seeds, since the first expence of seeds is not to be put in competition with the beauty and advantage of having such as are good; for when the land is brought to a good sward (which may be done in one year, where it is properly prepared and sown with good seeds) it may be kept in good order, and by good management improved annually, and will continue so, as long as proper care is taken of it. I know some land which was sown in the method hereafter directed above forty years ago, which are now as good pastures as any I have seen, and may be always continued so.

These grounds abounded with many bad weeds; so they had a winter and summer's fallow, in which time they were five times ploughed and ten times harrowed in order to destroy the weeds, and make the surface of the ground fine; in August they were sown with the best Grass-seeds as could be procured, three bushels of this, and nine pounds of the white Dutch Clover-seeds were allowed to each acre; as there happened rains soon after the seeds were sown, so the Grass came up well; but among it were a great number of weeds, which were drawn up and carried off the ground, and in the beginning of October the fields were rolled with a Barley roller; in the spring the fields were again weeded, and afterward rolled; and that summer there was more than two tons of hay per acre mowed off the land; and by constant weeding twice a year, sweeping it with a bush harrow, rolling and dressing of the land, the Grass has been greatly improved since, and is now as good pasture as any in England: and since I have laid down great quantities of land in the same manner, and with equal success; therefore from many years experience can recommend it, as the surest method of having good pastures.

But I know the generality of farmers will object to the first loss of their crop; and also to the after expence of weeding, rolling, &c. as too great for common practice: however, I am well satisfied from experience, that whoever will be at the expence, will find their account in it; for the crops of hay will be so much better, and the after pasture also, that it will more than pay the expence, as from many exact accounts, which have been kept of the whole, is sufficiently demonstrated, and the verdure of these pastures is charming to all those who have any taste of natural beauties.

The proper management of pasture land is the least understood of any part of agriculture; the farmers never have attended to this, being more inclined to the plough, though the profits attending that have not of late years been so great as to encourage them in that part of husbandry; but these people never think of laying down land for pasture, to continue longer than three years, at the end of which time they plough it up again, to sow it with grain.

There is a sort of striped Grass which is preserved in many gardens for the beauty of its variegated leaves, which continue fresh the greatest part of the summer. This sort is easily propagated by parting the roots, either in spring or autumn, for every offset will increase to be a large root in one year's time. It will grow on any soil or in any situation, therefore may be planted in any abject part of the garden, where it will thrive, and afford an agreeable variety. This sort is by many persons called Ribband-grass, from the stripes of white and green, which run the whole length of the blade, like the stripes in some ribbands.

For the further management of Grass in fields, see PASTURE and MEADOW; and for that in gardens, see GRASS.

GRASS. The English Grass is of so good a quality for walks or Grass-plats, that if they be kept in good order, they have that exquisite beauty that they cannot come up to in France, and several other countries. But green walks and green plats are, for the most part, not made by sowing the Grass-seed, but by laying turfs; and, indeed, the turfs from a fine common or down, are much preferable to sown Grass.
